S. *ſodomeum*. Dark-thorned Nightſhade. Linn. Sp. Pl. 268. Willd. n. 63. Ait. n. 29. Sm. Fl. Græc. Sibth. t. 235, unpubliſhed. (S. pomiferum fruteſcens africanum ſpinoſum nigricans, borraginis flore, foliis profundè laciniatis; Herm. Lugd. Bat. 573. t. 575. Tourn.

Inſt. 149. S. pomiferum, foliis quercûs utrinque ſpinoſis, flore borraginis; Moriſ. ſect. 13. t. 1. f. 15.)—Stem ſhrubby, round, prickly. Leaves deeply pinnatifid, roundly lobed, roughiſh, with ſcattered thorns. Calyx prickly, much ſhorter than the fruit.—Native of Africa, and the ſouth of Europe. A greenhouſe ſhrub, flowering in June and July. The *ſtem* is erect, branched, brown or purpliſh, more or leſs roughiſh, like the reſt of the herbage, with ſomewhat ſtarry hairs, and bearing, like the ribs of the *leaves* above and below, and all the *ſtalks*, copious, ſtrong, browniſh, ſcarcely black, ſtraight thorns, broad at the baſe. The *leaves* are green, very deeply, often doubly, pinnatifid, with wide ſinuſes, and blunt rounded lobes, like thoſe of ſome American oaks. *Cluſters* lateral, ſimple. *Flowers* large and handſome, purple, with ſhortiſh yellow *anthers*. *Calyx* very thorny. *Fruit* yellow, globoſe, pendulous, an inch or two in diameter.

S. *Pyracantha*. Orange-thorned Nightſhade. Lamarck Dict. v. 4. 299. Ait. n. 30. Sm. Exot. Bot. v. 2. 9. t. 64.—Stem ſhrubby, very thorny, as well as the foliage and calyx. Leaves oblong, acute, pinnatifid, denſely downy. Cluſters lateral, woolly.—Native of Madagaſcar. Sent by M. Thouin, in 1789, to Mr. Aiton. It flowers in the ſtove in Auguſt and September, but, according to Mr. Lambert, ſucceeds well during autumn, if turned out under a ſouth wall. The whole plant is rendered very brilliant by the copious, large, bright-orange thorns, and the downy ribs of the *leaves* are of the ſame rich hue. Each *leaf* is often a foot long, with ſpreading, parallel, acute, lanceolate, angular lobes, clothed on both ſides with denſe, white, ſtarry pubeſcence. *Branches* and *ſtalks* woolly. *Cluſters* ſimple. *Calyx* woolly, thorny at the baſe only; its ſegments linear-lanceolate. *Corolla* violet, with green branching veins. *Anthers* yellow, equal. *Stigma* ſimple. *Berry* globoſe, reddiſh.

S. *ſiſymbrifolium*. Rocket-leaved Nightſhade. Lamarck Dict. v. 4. 307.—Stem ſhrubby, thorny, as well as the foliage and calyx. Leaves doubly pinnatifid, acutely notched, hairy. Cluſters lateral, with hairy ſtalks. Stigma two-lobed.—Gathered at Buenos Ayres, by Commerſon, whoſe ſpecimen is before us. The *leaves* are not half ſo long as the laſt, but broader in proportion, and green, not white or hoary, their pubeſcence, and that of the whole herbage, being ſimply hairy, apparently viſcid, not at all ſtellated. The *thorns* are ſlender, of a tawny or orange hue, and are extremely abundant about the baſe of the *calyx*. *Cluſters* longer than the leaves, ſimple, of a few large, white, or bluſh-coloured, *flowers*, whoſe *ſtigma* is capitate, of two downy lobes.

S. *argentatum*. Silvery-coated Nightſhade.—Stem ſhrubby, prickly, as well as the foliage and calyx. Leaves oblong, obtuſe, bluntly ſinuated, clothed, like the ſtalks, calyx, and back of the corolla, with depreſſed, ſtarry ſcales.—Native of Buenos Ayres. We preſume this may be the ſuppoſed variety, mentioned by M. Poiret in Lamarck, with ſimply pinnatifid *leaves*. Probably that able botaniſt viewed it but ſlightly, for nothing can be more diſtinct than our plant, gathered by Commerſon, nor are many of its genus more elegant. The *leaves*, on long ſpinous *ſtalks*, are pretty exactly of the ſize and figure of our Common Oak, but thickly clothed on both ſides with curious ſtarry ſcales, rather than hairs, more denſe and hoary on the under ſurface, and more ſilvery on the *flower-ſtalks*, *calyx*, and even the back of the *corolla* itſelf. The *thorns* of the whole plant are ſlender, and orange-coloured. The *calyx* is bell-ſhaped, angular, with ſhort ſlender teeth; its baſe prickly.

S. *cornutum*. Horn-flowered Nightſhade. Lamarck Dict. v. 4. 308. "Juſſ. Annal. du Muſ. d'Hiſt. Nat. v. 3. 120. t. 9;" *Purſh*.—Stem herbaceous, thorny, as well as the foliage and calyx. Leaves doubly pinnatifid, lyrate, nearly ſmooth. Anthers declining; the lower one much the largeſt.—Native of Vera Cruz, from whence Thierry de Menonville brought ſeeds to the Paris garden. We know not whether the *root* or *ſtem* be perennial or no, but the plant ſeems of luxuriant growth, with copious, long, ſlender, pale-yellow thorns. The *leaves* are green, not hairy, but roughiſh with minute points, at leaſt in a dry ſtate; the whole leaf, as well as each diviſion, particularly the terminal one, elegantly lyrate; the ribs beſet with fine briſtly thorns. *Cluſters* lateral, denſe, with ſlightly downy ſtalks. *Flowers* large, yellow, remarkable for the great ſize of their lowermoſt *anther*.

S. *heterandrum*. North American Horned Nightſhade. Purſh n. 6.—Stem herbaceous, thorny, as well as the foliage and calyx. Leaves doubly pinnatifid, hairy and downy on both ſides; their ſegments obtuſe. Anthers ſpreading; the lower one as long as the corolla. Berry encloſed in the armed calyx.—Found by Mr. Nuttall, on the banks of the Miſſouri, flowering in July. Annual, with large yellow *flowers*. Nearly allied to the laſt. *Purſh*.

S. *capenſe*. Thorny Cape Nightſhade. Linn. Suppl. 147. Willd. n. 64. Thunb. Prodr. 37.—Stem ſhrubby, round, thorny, as well as the foliage and calyx. Prickles crowded, ſtraight. Leaves bluntly pinnatifid, rough with ſtarry hairs. Fruit-ſtalks lateral, in pairs, unarmed, recurved.—Brought by Thunberg from the Cape of Good Hope. The *ſtem* is woody, very much branched, knotty, rigid, apparently of humble ſtature, armed with plentiful, ſharp, ſtraight, tawny prickles, from a quarter to half an inch long; the young *branches*, and *ſtalks*, clothed with lax ſtarry hairs. The *leaves* are ſtalked, barely an inch long, ſinuated like an oak-leaf, with two rounded lobes at each ſide, bearing a few large prickles, and clothed all over with the ſame ſtarry pubeſcence as the ſtalks, though deſcribed by the younger Linnæus and Thunberg as naked. The *flowers* we know nothing of. *Berries* globoſe, orange-coloured, poliſhed, naked, the ſize of Black Currants, two or three together, on ſtrong recurved *ſtalks*, ſhorter than the leaves, and almoſt entirely deſtitute of prickles, though the deeply-divided calyx bears ſeveral large ones. No figure, nor, till now, any full deſcription, of this ſpecies has been publiſhed.

S. *marginatum*. White-margined Nightſhade. Linn. Suppl. 147. Willd. n. 65. Ait. n. 31. Jacq. Coll. v. 1. 50. Ic. Rar. t. 45.—Stem ſhrubby, woolly, prickly, as well as the foliage and ſtalks. Leaves heart-ſhaped, waved or ſinuated, white-edged; denſely woolly beneath.—Said to have been brought by Mr. Bruce, the celebrated traveller, from Abyſſinia, or at leaſt from Africa, and introduced at Kew in 1775. Jacquin gives Paleſtine as its native country. This is a handſome greenhouſe *ſhrub*, flowering moſt part of the ſummer, and diſtinguiſhed by the pure-white margin of its rather large *leaves*, on the upper ſide, eſpecially when young. The ſnowy, granulated, minutely ſtarry pubeſcence of the whole plant, very denſe on the backs of the *leaves*, is alſo ſtriking. The *prickles* are ſmall and few. *Flowers* the ſize of a potatoe-bloſſom, cymoſe, with purple ribs. *Calyx* woolly, unarmed, ſplitting unequally. *Fruit* ovate, of a dirty yellow.

S. *Veſpertilio*. Bat-flowered, or Canary, Nightſhade. Ait. ed. 1. v. 1. 252. ed. 2. n. 33. Willd. n. 67. Wendl. Hort. Herrenh. faſc. 4. 5. t. 21. (Nycterium cordifolium; Venten. Malmaiſ. t. 85.)—Stem ſhrubby, prickly. Prickles conical. Leaves heart-ſhaped, undivided; woolly beneath.

Corolla irregular. Lower anther greatly elongated.—Brought by Mr. Maſſon, from the Canary iſlands, in 1779. A greenhouſe ſhrub, flowering in March and April. The upright branching *ſtem* is armed with abundance of ſhort, ſtraight, conical, browniſh *prickles*. *Leaves* the ſhape and ſize of thoſe of the *Catalpa;* green, beſprinkled with minute ſtarry hairs, above; denſely downy, and hoary, beneath. *Flowers* about the ſize of the laſt, and in like manner lateral and cymoſe, often, if not always, four-cleft and tetrandrous, their *ſtalks*, unarmed *calyx*, and back of the purple irregular *corolla*, covered with ſtarry down. Lowermoſt *anther* declining, ending in a long recurved beak, as in *S. cornutum* and *heterandrum*, already deſcribed, upon which character principally Ventenat founds his genus of *Nycterium*, ſo called from νυκτερις, *a bat*. Such a genus would differ from *Solanum* nearly as *Celſia* does from *Verbaſcum*, and if ſeveral more ſpecies ſhould occur, it might, for convenience at leaſt, be adopted.

S. *tomentoſum*. Woolly Nightſhade. Linn. Sp. Pl. 269. Willd. n. 70. Ait. n. 34. Thunb. Prodr. 36. (S. coccineum; Jacq. Miſc. v. 2. 329. Ic. Rar. t. 43. S. ſpinoſum, maximè tomentoſum; Bocc. Sic. 8. t. 5. f. 1.)—Stem ſhrubby, with a few briſtly prickles. Leaves heart-ſhaped, unarmed, wavy, clothed with denſe ſtarry wool on both ſides.—Native of the Cape of Good Hope; introduced into the European greenhouſes about the middle of the 17th century. A pretty ſpecies, with a zig-zag *ſtem* of no great elevation, its branches and whole herbage remarkably woolly and white, with a few ſcattered, minute, needle-like prickles, eſpecially on the *flower-ſtalks*. The pubeſcence of the young budding *leaves* is uſually tinged with violet. *Calyx* bell-ſhaped, cloven half way down, unarmed. *Corolla* purple or lilac, woolly at the outſide. *Fruit* globoſe, of a beautiful ſcarlet, varying in ſize from that of a pea to a ſmall gooſeberry.

S. *giganteum*. Tall Snowy-leaved Nightſhade. Jacq. Coll. v. 4. 125. Ic. Rar. t. 328. Willd. n. 74. Ait. n. 36. (S. niveum; Thunb. Prodr. 36. Vahl. Symb. v. 2. 41.)—Stem ſhrubby, armed with downy conical prickles. Leaves elliptic-lanceolate, acute, unarmed; ſmooth above; ſnow-white and downy beneath. Cluſters terminal, forked, cymoſe. Fruit erect.—Native of the Cape of Good Hope. Introduced by Mr. Maſſon, in 1792. A greenhouſe ſhrub, flowering in June and July, of a tall and ſtriking habit, like that of ſome *Echium* or *Tournefortia*. The *branches* are thick and round. *Prickles* copious, ſhort. *Leaves* numerous about the tops of the branches, from three to five inches long, ſtalked, recurved; dark green above; peculiarly white and ſoft beneath. *Flowers* numerous, purple, rather ſmall, drooping, on corymboſe ſtalks, which become entirely erect as the *fruit* advances.

S. *rubiginoſum*. Ruſty Nightſhade.—Stem ſhrubby, armed, like the footſtalks and ribs of the leaves, with hooked prickles. Leaves elliptical, acute; nearly naked above; downy and ruſty beneath. Cluſters terminal, forked, cymoſe. Corolla downy.—Gathered in Cayenne by Mr. Von Rohr, who ſent it to ſir Joſeph Banks as the *S. rubiginoſum* of Richard. But we find no ſuch name in the catalogue of Cayenne plants by this botaniſt, in the Actes de la Soc. d'Hiſt. Nat. de Paris, v. 1. 105. Aublet appears by his herbarium to have called this ſpecies *rhamnoides*, but it does not occur in his book. The dried ſpecimen is diſtinguiſhed by a peculiarly ſtriking ruſty tint, which may poſſibly not be ſo ſtrong in the living plant. The *branches* are round, covered with brown, minutely ſtarry, cloſe down, and armed with numerous, ſmall, ſmooth, very ſharp, ſtrongly hooked prickles. *Footſtalks* an inch long, angular, ſimilarly clothed and armed. *Leaves* three or four inches in length, and an inch and a half in breadth, entire, with one rib, prickly in the lower part, and many interbranching veins; their upper ſurface green, ſhining, ſmooth and naked, except a few ſcattered, rigid, ſtarry hairs, which cauſe a roughneſs to the touch; under ſurface marked with prominent veins, and denſely covered with cloſe, ſhining, ruſty or whitiſh, ſoft, ſtarry down. *Infloreſcence* ſimilar to the laſt, to which this fine ſpecies ſeems moſt akin, but the *ſtalks*, *calyx*, and under ſide of the *corolla*, are clothed with ruſty ſtarry pubeſcence. The *branch* is ſubſequently continued beyond the *flowers*.

S. *polyacanthos*. Many-thorned Nightſhade. Lamarck Tabl. Encycl. v. 2. 23. n. 2377. Dict. v. 4. 304 Willd. n. 79. (S. parviflorum; Cavan. Ic. v. 3. 19. t. 236. Phytolacca fruteſcens ſpinoſiſſima, foliis anguſtis et criſpis; Plum. Ic. 218. t. 224. f. 1.)—Stem ſhrubby, very prickly as well as the foliage. Prickles long, ſtraight, and ſlender. Leaves linear-lanceolate, obtuſe, ſlightly waved, nearly ſeſſile, hairy. Stalks axillary, ſingle-flowered.—Native of Hiſpaniola, where our ſpecimen was gathered by Thierry. The whole herbage is exceſſively prickly, with yellow needle-like thorns, green, rough with ſtarry hairs, not hoary. *Leaves* copious, an inch and a half long, rather convex, all ſimple and undivided. *Flowers* very ſmall, ſolitary, drooping, white. *Berry* globoſe, hardly bigger than a muſtard-ſeed. *Calyx* unarmed.

S. *igneum*. Red-ſpined Nightſhade. Linn. Sp. Pl. 270. Willd. n. 80. Ait. n. 37. Jacq. Hort. Vind. v. 1. 5. t. 14. (S. ſpiniferum fruteſcens, ſpinis igneis, americanum; Pluk. Phyt. t. 225. f. 5.)—Stem ſhrubby, prickly, as well as the footſtalks and foliage. Prickles ſcattered, ſomewhat conical, ſhining. Leaves lanceolate, entire, ſlightly downy on both ſides.—Native of South America. Cultivated for more than 100 years paſt in the ſtoves of this country, where it is moſt conſpicuous for the little ſhining flame-coloured thorns, ſometimes making the ſhrub look as if on fire. The *branches* are round. *Leaves* ſtalked, green, three or four inches long. *Flowers* white, often only four-cleft, in ſlender, ſimple, lateral cluſters.

S. *ſtelligerum*. Starry Nightſhade. Sm. Exot. Bot. v. 2. 57. t. 88. Brown. n. 8.—Stem ſhrubby, prickly, with taper thorns. Leaves lanceolate, entire, unarmed; ſmooth above; denſely woolly and veiny beneath. Wool ſtarry. Corymbs lateral.—Native of New South Wales, as well as of the tropical part of New Holland, in which laſt-mentioned country the prickles were obſerved by Mr. Brown to be more perfectly ſtraight. This pretty ſpecies has not yet appeared in any garden. The *ſtem* is buſhy, from three to five feet high, with round, downy, leafy, prickly *branches*, but every other part is unarmed. *Leaves* about three inches long, on woolly *ſtalks;* their upper ſide green, ſhining, quite ſmooth except the rib; under covered with denſe white wool, compoſed of ſtarry hairs, elevated on ſtalks. *Flowers* numerous, three-quarters of an inch broad, light blue, with orange *anthers*, each of whoſe terminal pores is cloſed by a ſeparate lid. *Berries* ſcarlet, erect, the ſize of a currant, not longer than the lanceolate ſegments of their unarmed *calyx*.

S. *Milleri*. Miller's Nightſhade. Jacq. Coll. v. 4. 209. Ic. Rar. t. 330. Willd. n. 81. Ait. Epit. 374. (S. trilobatum, floribus parvis albis; Linn. Sp. Pl. 270. S. Schiru-ſchuna; Mill. Dict. ed. 8. n. 32.)—Stem ſhrubby, armed with hooked compreſſed prickles. Leaves ſinuated or pinnatifid, obtuſe, ſlightly prickly, ſmooth. Stalks moſtly in pairs, ſingle-flowered.—Native of the Cape of Good Hope. Cultivated by Miller in 1762, but we know not whether it exiſts at preſent in any garden. The *branches* are irregular and ſpreading, bearing copious tawny prickles, ſhaped like thoſe of a wild briar. *Leaves* ſtalked, an inch or inch and half long, green, ſinuated like thoſe of an oak. *Flowers* ſmall, white, not unlike thoſe of *S. nigrum*, but their *calyx* is thorny. *Berries* black, reſembling the fruit of that ſpecies.

S. *trilobatum*. Three-lobed Nightſhade. Linn. Sp. Pl. 270. Willd. n. 82. Ait. n. 38. Burm. Ind. 57. t. 22. f. 2.—Stem ſhrubby, armed with hooked compreſſed prickles. Leaves angular, ſomewhat three-lobed, obtuſe, unarmed, ſmooth. Flowers racemoſe.—Native of the Eaſt Indies. Cultivated by Miller in 1759. A ſtove-plant, flowering in Auguſt. More ſlender than the laſt, with more diſtant, and leſs ſinuated *leaves*, on longer *ſtalks*. But the much larger purple *flowers*, in double-branched lateral *cluſters*, eſſentially diſtinguiſh the preſent plant, whoſe *branches* and *leaves*, the prickles excepted, might be thought to belong to ſome ſpecies of *Boerhavia*. Plukenet's t. 316. f. 5, is rather more like *S. Milleri*, but cannot be preciſely determined, for want of the infloreſcence.

Section 3. *Branches ending in thorns.* One ſpecies.

S. *lycioides*. Box-thorn Nightſhade. Linn. Mant. 46. Willd. n. 83. Ait. n. 39. Jacq. Coll. v. 1. 96. Ic. Rar. t. 46.—Stem ſhrubby; branches with terminal thorns. Leaves elliptical. Flowers ſolitary.—Suppoſed to be a native of Peru. A ſtove-plant in England, flowering in May and June. Its habit is correctly compared by Linnæus to that of a *Lycium*. The *ſtem* is woody, with many long, trailing, ſlender, angular, ſmooth, leafy *branches*, finally becoming ſpinous at the extremity. *Leaves* ſtalked, about an inch long, ſmooth, entire. *Flowers* elegant, ſolitary, on lateral ſlender ſtalks, an inch in length. Segments of the *calyx* narrow, ſmooth. *Corolla* light-blue. *Anthers* ſhort, orange. *Berry* ſcarlet, the ſize of a currant.

Notwithſtanding our having here added twelve ſpecies to Willdenow's liſt, we are conſcious that many ſtill remain unſettled, of which we have only imperfect or uncertain ſpecimens. The tropical regions of Africa probably poſſeſs ſeveral more. Beſides thoſe we have noticed, Mr. Brown defines fourteen new ſpecies in his *Prodromus* of the Flora of New Holland, under the following names. *S. tetrandrum*, *viride*, and *biflorum*, without prickles. *S. diſcolor*, *violaceum*, *furfuraceum*, *parvifolium*, *ellipticum*, *armatum*, *Hyſtrix*, *cinereum*, *pungetium*, *campanulatum*, and *echinatum*, with prickles on the ſtem, ſtalks, leaves or calyx. Among theſe the *Hyſtrix* is moſt remarkable for having prickles on the corolla itſelf.

SOLANUM, in *Gardening*, contains plants of the herbaceous, ſhrubby, and tuberous-rooted, eſculent kinds, of which the ſpecies cultivated are: the love-apple, or tomato (S. lycoperſicum); the Ethiopian nightſhade (S. æthiopicum); the large-fruited nightſhade, or egg-plant (S. melongena); the woody nightſhade, or bitter-ſweet (S. dulcamara); the mullein-leaved nightſhade (S. verbaſcifolium); the ſhrubby nightſhade, or winter cherry (S. pſeudocapſicum); the oak-leaved nightſhade (S. quercifolium); the dug-fruited nightſhade (S. mammoſum); the Indian nightſhade (S. indicum); the Carolina nightſhade (S. carolinenſe); the black-ſpined nightſhade (S. ſodomeum); the Paleſtine nightſhade (S. ſanctum); and the tuberous-rooted nightſhade, or common potatoe (S. tuberoſum).

In the firſt ſort the fruit is ſmooth, but varies in form, ſize, and colour, from which Miller has formed two varieties; the firſt of which is commonly cultivated in the ſouth of Europe to put into ſoups and ſauces, to which it imparts an agreeable acid flavour: the fruit is very large, compreſſed both at top and bottom, and deeply furrowed all over the ſides, and of a red-yellow or yellowiſh colour. The latter is round, about the ſize of a large cherry, either yellow or red. It is a native of South America, flowering from July to September.

And in the third ſort there are varieties with oblong violet-coloured fruit, with an oblong, white, large fruit, with a globular violet-coloured fruit, and with a globular white or variegated fruit. Some make other varieties, as red-fruited, yellow-fruited, prickly-fruited, &c.

Alſo in the fourth ſort there are varieties with fleſh-coloured, with white flowers, and with variegated leaves. Some have likewiſe gold ſtriped-leaved, African thick-leaved, &c.

The ſixth ſort has alſo varieties with red and with yellowiſh fruit.

In the laſt ſort, which is probably a native of Peru, or ſome part of that tract of continent, the principal varieties may be diſtinguiſhed into two kinds, as the red-rooted and white-rooted ſorts; the ſub-varieties of which are extremely numerous; but for garden purpoſes, the following are the moſt uſeful kinds that are generally employed.

The early dwarf-red, the round-red, the oblong-red, the pale-red, the blood-red, the Iriſh red or painted lord, old winter-red, rough-red, and ſmooth-red.

Early forcing potatoe, the early dwarf-white, brown early, Cumberland early, early Scot, golden dun, early champion, white bloſſom, Manly white, kidney-white and red, red-noſed, true white, flat white, and ſuperfine white early.

Many other kinds or varieties are made uſe of in gardens for raiſing the late as well as the early crops of this moſt uſeful root. In Lancaſhire, for the very early crops, they have principally recourſe to the early kings, and foxes ſeedlings.

They alſo cultivate a ſmall everlaſting potatoe, as it is called, in the ſame ſituations, covering the beds with ſtraw or ſome other material in the winter ſeaſon, when neceſſary. A ready ſupply of the root may, it is ſaid, be provided in this way by this ſort of potatoe.

In the firſt volume of the Tranſactions of the Horticultural Society of London, ſir Joſeph Banks has given the following curious and intereſting account of the introduction of this ſpecies of ſolanum, or the common potatoe, into this country and Europe. The notes from which this account has been principally taken, have, it is ſaid, been ſome of them collected from authorities of difficult acceſs by the learned and very intelligent Mr. Dryander.

It is ſtated, that the potatoe now in uſe was brought to England by the coloniſts ſent out by ſir Walter Raleigh, under the authority of his patent, granted by queen Elizabeth "for diſcovering and planting new countries, not poſſeſſed by Chriſtians," which paſſed the great ſeal in 1584. Some of ſir Walter's ſhips ſailed in the ſame year, others, on board of one of which was Thomas Herriot, afterwards known as a mathematician, in 1585; the whole of them, however, returned, and probably brought with them the potatoe, on the 27th of July, 1586.

The ſaid Thomas Herriot, who was probably ſent out, as it is ſaid, to examine the country, and report to thoſe who employed him the nature and produce of the ſoil, wrote an account of them, which is printed in the firſt volume of De Bry's Collection of Voyages. In this account, under the article of roots, in p. 17, he deſcribes a plant which is called Opanawk. "Theſe roots are," he ſays, "round, ſome as large as a walnut, others much larger; they grow in damp ſoil, many hanging together, as if fixed on ropes: they are good food either boiled or roaſted."

Gerarde in his Herbal, publiſhed in the year 1597, gives a figure of the potatoe, under the name of the potatoe of Virginia, and aſſerts, that he received the roots from Virginia, which are otherwiſe denominated Norembega.

The manuſcript minutes of the Royal Society, 13th of December, 1693, aſſure us, that ſir Robert Southwell, then preſident, informed the fellows, at a meeting, that his grandfather brought potatoes into Ireland, who firſt had them of ſir Walter Raleigh.

This evidence, it is ſuppoſed by ſir Joſeph, proves, in no ſatisfactory manner, that the potatoe was firſt brought into England, either in the year 1586, or very ſoon after that period, and ſent from thence to Ireland without delay, by ſir Robert Southwell's anceſtor, where it was cheriſhed and cultivated for food before the good people of England knew its value; for Gerarde, who had this plant in his garden in 1597, recommends the roots to be eaten as a delicate diſh, not as common food.

It appears, however, he ſays, that it firſt came into Europe at an earlier period, and by a different channel; for Cluſius, who at that time reſided at Vienna, firſt received the potatoe, in 1598, from the governor of Mons, in Hainault, who had procured it the year before from one of the attendants of the pope's legate, under the name of Taratonfli; and learned from him, that in Italy, where it was then in uſe, no one certainly knew whether it originally came from Spain, or from America.

Peter Cicca, in his Chronicle, which was printed in 1553, tells us, it is ſaid, in chap. xl. p. 49, that the inhabitants of Quito, and its vicinity, have, beſides mays, a tuberous root, which they eat, and call papas; this Cluſius gueſſes to be the ſame ſort of plant he received from Flanders, and this conjecture has, it is ſaid, been confirmed by the accounts of travellers, who have ſince that period viſited the country.

It is concluded that, from theſe details, it may fairly be inferred, that potatoes were brought into Europe from the mountainous parts of South America, in the neighbourhood of Quito; and that, as the Spaniards were the ſole poſſeſſors of that country, there can be little doubt of their having been carried firſt into Spain, but that as it would take ſome time to introduce them into uſe in that country, and afterwards to make the Italians ſo well acquainted with them as to give them a name, there is every reaſon to believe, that they had been ſeveral years in Europe before they were ſent to Cluſius.

As the name of the root in South America is papas, and in Virginia that of opanawk; the name of potatoe was, it is ſaid, evidently applied to it on account of its ſimilarity in appearance to the battata, or ſweet potatoe; and our potatoe appears to have been diſtinguiſhed from that root, by the appellation of potatoe of Virginia, until the year 1640, if not longer.

It is added, that ſome authors have aſſerted, that potatoes were firſt diſcovered by ſir Francis Drake in the South ſeas, and others, that they were introduced into England by ſir John Hawkins; but in both inſtances, the plant alluded to is, it is ſaid, clearly the ſweet potatoe, which was uſed in England, as a delicacy, long before the introduction of our potatoes; it was imported, it is ſaid, in conſiderable quantities, from Spain and the Canaries, and was ſuppoſed to poſſeſs the power of reſtoring decayed vigour. The kiſſing comfits of Falſtaff, and other confections of ſimilar imaginary qualities, with which our anceſtors were duped, were, it is ſaid, principally compoſed of theſe, and eringo roots.

It is alſo further noticed, that the potatoes themſelves were ſold by itinerant dealers, chiefly in the neighbourhood of the Royal Exchange, and purchaſed, at no inconſiderable coſt, by thoſe who had faith in their alleged properties. The alluſions to this opinion are, it is obſerved, very frequent in the plays of that age.

Method of Culture.—Theſe plants, from the great differences in their natures, habits of growth, and other qualities, muſt evidently require different modes of cultivation and management.

Culture in the Annual Kind. — The three firſt ſpecies, which are of this ſort, may be raiſed from ſeed, which ſhould be ſown in the early ſpring on hot-beds, moulded over to the depth of ſix or ſeven inches with light rich mould, in drills or pots plunged into the beds. When the plants come up, they ſhould be properly thinned, have a pretty free admiſſion of air, and occaſional waterings; and the love-apple kinds, when they have attained ſome growth, as five or ſix inches, and the weather becomes ſettled warm, ſhould be removed into the open ground, planting them in a warm ſheltered border, and placing them at a conſiderable diſtance. Some may be trained againſt a ſouth fence, to have the advantage of the full ſun: they ſhould always be ſupported by ſome means or other to ſhew themſelves, and ripen their fruit. But the egg-plants ſhould be pricked out, when a few inches in height, into another hot-bed prepared for the purpoſe, at the diſtance of four or five inches; and ſome may be put in ſeparate pots, and plunged in the bed, giving water and ſhade till they are freſh rooted; the waterings ſhould be duly repeated, and freſh air freely admitted, when the weather is fine: it may alſo be requiſite to remove them with balls about their roots to a third hot-bed, in order to have them very fine and ſtrong: the frame ſhould be raiſed as they advance in growth, and when the weather becomes fine and hot, they ſhould be gradually hardened, and finally ſet out in the pots, &c. where they are wanted.

Culture in the Hardy Shrubby Kind.—The fourth ſort, which is of this nature, may be increaſed by layers and cuttings, which may be laid down or planted out in the autumn or ſpring, where they will be well rooted by the following autumn, when they may be taken off and removed into nurſery-rows, or where they are to grow for good.

Culture in the Shrubby Greenhouſe Kind.—Likewiſe all the eight following ſorts, which are of this deſcription, may be increaſed by ſeeds, which ſhould be ſown thinly in rich light earth in the early ſpring in ſmall pots, plunging them in the hot-bed under frames and glaſſes, watering them frequently, when the plants will ſoon come up, admitting freſh air daily; and when the plants are about two inches high, they ſhould be pricked out upon another hot-bed, giving water and ſhade, till they are freſh rooted; and ſome may be put into pots, plunging them in the bed. As the warm weather advances, they ſhould be gradually hardened to the open air, ſo as to be ſet out into it about the middle of the ſummer, when the weather is mild and fine.

And they ſhould afterwards be managed as other ſhrubby exotic greenhouſe plants.

There are alſo many of the tender ſhrubby hot-houſe or ſtove kinds, that are highly deſerving of cultivation, ſuch as the fiery-thorned American, Guinea, tomentoſe trilobate, and ſeveral other ſpecies.

Theſe may all be increaſed by ſowing the ſeeds of them, in the ſpring, in pots of light earth, to be plunged into a hot-bed;

hot-bed; when the plants are come up two or three inches in height, they ſhould be pricked out ſeparately into ſmall pots, which are alſo to be plunged into the hot-bed or bark-bed of the ſtove, afterwards managing them as other ſhrubby exotics of the ſtove kind. The propagation and increaſe of them may likewiſe be tried, in ſome caſes, by cuttings, which are to be ſet or planted in pots, and the whole plunged into the bark-bed, covering them cloſe down by means of a hand-glaſs.

All theſe plants muſt be conſtantly kept in pots filled with light rich earth, and be retained, the moſt part of the year, in the ſtove, among collections of that ſort, except for juſt a month or two in the height of the ſummer, when the heat is conſiderable. In this way they not unfrequently ſucceed very well.

Theſe plants, in all the ſorts, are very ornamental among other potted plants; and the firſt is cultivated likewiſe for the fruit as a pickle: the fourth is alſo ornamental in the borders, &c. of gardens and ſmall pleaſure-grounds.

Culture in the Potatoe Kind.—This laſt ſort is highly valuable for its tuberous eſculent root, which is well known under the title of potatoe. Theſe roots may be obtained for uſe plentifully almoſt the year round: the early ſorts, being planted forward in the ſpring, often afford tolerable crops fit to take up in the beginning of June and in July following, eſpecially in rich warm grounds; but the main crops are permitted to continue growing till autumn, as about the latter end of October or beginning of November, when the ſtalks or haulm begin to decay, at which time the roots will be arrived to full maturity: and being then taken out of the ground, and houſed in ſome cloſe dry apartment, keep in good perfection for eating all winter and ſpring, until the arrival of the new crops in the following ſummer.

With regard to the properties of the different ſorts or varieties of this root, ſo far as they relate to their uſefulneſs as food, or their nouriſhing qualities, there is probably no very material difference; but inſomuch as their agreeableneſs for the purpoſe of eating by man is concerned, there is conſiderable diverſity, ſome ſorts being naturally farinaceous and mealy, while other kinds are heavy and clayey, or waxy, the former of which are, for the moſt part, highly deſirable and greatly reliſhed, while the latter are diſagreeable to and diſreliſhed by many. The red ſorts were formerly held in great eſteem, and ſuppoſed the beſt; and though they are moſt probably in no reſpect inferior to thoſe of the white kinds, theſe have of late, in general, been much preferred, eſpecially the round, the oblong-white or whitiſh red, and the kidney ſorts, as being more productive, more ſaleable in the markets, and the moſt deſirable for eating.

This has cauſed the culture of the large red ſort to be in a great degree overlooked and neglected, though ſome think that the potatoes of this kind are ſuperior to thoſe of the white ſort in the richneſs of their flavour and ſome other qualities.

As both ſorts, however, poſſeſs good qualities in different ways, the beſt and moſt uſeful varieties, in each kind, ſhould be cultivated in ſufficient and ſuitable proportions. The early ſorts are, however, the moſt proper and ſuitable for being cultivated in gardens in moſt caſes.

It is of importance in the garden, as well as the field, to have good-ſized potatoes for ſets, or for taking the ſets from, whatever the ſort may be, as the very ſmall potatoes, or chats, as they are called, never anſwer well in this intention. And it is equally important to have a frequent change of the ſeed or ſets which are employed for raiſing the crops, as every two or three years, new, or ſuch potatoes as are freſh from other grounds, being found highly uſeful in preventing degeneracy and promoting the goodneſs and abundance of the crops, as well as in obviating their tendency to the curl, which is ſo greatly injurious to them.

The potatoe is an annual plant, which leaves offsets, tubers, or roots, for its future propagation and increaſe.

All the varieties may be cultivated with ſucceſs in any open ſituation. They delight in a moderately light rather dry ſoil and open ſituation, which ſhould be rendered light with dung. The plants are increaſed by the root, either whole or cut in pieces, each cutting forming a proper ſet or plant. This is their general method of cultivation; but they may likewiſe be raiſed from ſeed to gain new varieties.

In moſt places the general ſeaſon for planting this root is from about the middle or the latter end of February to the middle of April; the early ſorts, for forward crops, being planted in the latter end of February or early in March; but for the general crops, March, and the firſt fortnight in April, is the moſt proper planting ſeaſon, eſpecially in moiſt land; as, if planted earlier, and much wet ſhould ſucceed, it would rot the ſets, more particularly if cuttings; though in caſes of neceſſity, where the ground is not ready before, they may be planted any time in April, or even in May, and yield tolerable crops by October. And the ground for this purpoſe ſhould always be dug over for the reception of the plants to one full ſpade deep.

But as to the planting, it may be performed by means of a dibble, by holeing in with a ſpade, or drilling in with a hoe, bedding in, &c. in rows at two feet aſunder, eight, twelve, or fifteen inches diſtant in each row, and not more than four or five inches deep at the moſt.

Dibble-planting.—This is performed either with a common large garden dibble, blunted at the bottom, making holes four or five inches deep, at the diſtance before mentioned, dropping one ſet into each hole as you go on, and ſtriking the earth in over them, or raking it afterwards, which is a better method.

The ſurface of the ground ſhould, ſome time afterwards, be further raked, and left perfectly even and level.

Drill-planting.—In this mode the drills may be formed either with a large hoe, two feet aſunder, and four or five inches deep, in which drop the ſets a foot aſunder, and cover them in with the earth equally the depth of the drill; or the drills may be made with a ſpade, and the ſets covered in by means of a rake, the ground being left quite even on the ſurface.

Furrow-planting.—This is performed by the ſpade, by turning over or taking out a ſpit of earth all along, putting in the dung, and then dropping the ſets in the furrow immediately upon it, and with the next ſpit turning the earth in upon the ſets of the firſt; and in another furrow, two feet from this, putting in the dung and dropping another row of ſets, which are covered in as above, and ſo on till the whole is finiſhed.

Holeing-in planting.—This is performed with a ſpade. A man having a light handy ſpade, and beginning at one end of the line, takes out a ſpit of earth, forms a ſmall aperture four or five inches deep, another perſon directly following after drops a ſet in the hole, the earth of the next ſpit immediately covers it up, and ſo on to the end of the work.

Trenching-in planting.—This is ſometimes practiſed in light ground, and is effected as the perſon proceeds in digging or trenching the ground, being trenched in the common way, each trench two ſpades wide, and one ſpade deep, placing one row of potatoes in each trench: beginning at one end of the ground, opening a trench the proper width and depth, as above, then paring in the top of the next trench deeply, putting it with ſome good dung in the bottom of the firſt, levelling it evenly, then digging along about half the width of the next or ſecond trench, turning the earth into the firſt upon the dung, only two or three inches in depth, and upon which lay the potatoe-ſets in a row along the middle eight or ten inches or a foot or more aſunder; then digging along the reſt or whole width of the ſaid ſecond trench a moderate ſpade deep, turning the earth of it into the firſt trench, over the ſets, three or four inches deep; this done, dung the bottom of the open trench, and proceed with the digging and planting as before; and continue trench and trench to the end of the work.

Bedding-in planting.—This is ſometimes done in low wet-tiſh land, for the ſake of raiſing the beds, and ſinking the alleys deep enough to drain off the too copious moiſture, and is thus performed:—the ground is divided into four, five, or ſix-feet wide beds, with alleys two or three feet wide between bed and bed; and the beds being dug, the potatoe-ſets are placed upon a little littery dung on the ſurface in rows lengthwiſe; and then the alleys dug out a ſpade deep, caſting the earth over the ſets about three or four inches thick; or the alleys may be firſt dug out to raiſe the beds, and the ſets then planted with a dibble in the common method: thus, by either of theſe methods, in wet ground, the alleys being ſunk, and the beds raiſed, the alleys drain off the redundant moiſture, which might rot the ſets before they begin to ſprout out and grow.

And this method of planting is ſometimes performed on graſs or ſward-land, marking out beds as above, with alleys between of proportionable width; then, without digging the beds, the potatoe-ſets are placed immediately upon the ſward at proper diſtances; the alleys being then dug and the ſpits turned graſs-ſide downward upon the beds over the ſets, covering them the proper depth as above, in which, if any additional depth is wanted, it may be ſupplied from the under earth of the alleys; and thus the ſets being between two ſwards, grow, and often are productive of very good crops, if permitted to have full growth. This is a ſort of lazy-bed mode of planting, that is not to be much practiſed in gardens.

In the after-management of the crops, where weeds begin to over-run the ground, two or three hoeings ſhould be given to kill them and looſen the ſurface of the ſoil; and when the plants have ſome growth, ſome hoe up a ridge of earth cloſe to each ſide of every row of plants in the firſt or ſecond hoeing, to ſtrengthen their growth more effectually, and render them more prolific, as the bottom of the ſtalks ſo landed up generally emits roots in the earth that become productive of potatoes the ſame as the principal roots.

In October, when the potatoes are full grown, they ſhould in the general crops be wholly taken up before they are attacked by froſt, and depoſited in ſome dry apartment for keeping: ſome may however be taken up before for occaſional uſe: this buſineſs is uſually performed by a three-pronged fork, the ends of the prongs being a little blunted. The early crops are to be taken up as they are wanted for uſe, as ſeen below.

Before the potatoes are begun to be dug up, whether in the early or late crops, the haulm ſhould be cut cloſe to the ground and cleared away, in the former only to the extent of what is to be taken up at the time, but in the latter for the whole ſpace which is to be dug up in the day, or other length of time, or for the quantity there may be. It is to be turned off in heaps on to the dug land, that the ſurface of the ground to be dug for potatoes may be rendered perfectly clear and convenient for the work. This is uſually done as the workman proceeds. In forking the crop up, the labour then goes on, by firſt opening a trench along one end of the ground to the depth and width of a good ſpit, proceeding in the ſame way with the reſt, throwing the whole of the potatoes, as they are dug up, into large baſkets placed for the purpoſe, carefully digging over all the land in a regular manner ſpit by ſpit, turning each clean upſide down into the previous open trench. In this manner the whole is to be completed.

The early crops are beſt taken up as they are wanted, as they do not keep ſo good when dug up in large quantities.

The haulm is ſometimes burnt, in the heaps as they lie upon the ground, but it is probably better to make uſe of it as litter, or to employ it for ſome garden purpoſes, which it may be made to anſwer.

When become perfectly dry and well freed from dirt and other matters, the potatoes may be put up and ſecured in the houſe, when for keeping, all the cut and bruiſed ones, as well as the chats or very ſmall ones, being previouſly ſorted out and taken away. Towards the ſpring they may likewiſe be rubbed over to take off the ſprouts and make them keep better.

When it is intended to raiſe new varieties from ſeed, ſome of the firſt flowering plants ſhould be marked, the ſeed ſhould be gathered in autumn when full ripe, and in the March or April following ſown in ſome light ſoil, in an open ſituation, in ſhallow drills a foot aſunder; and when the plants come up, they ſhould be kept clear from weeds till autumn, when, about the end of October or beginning of November, the roots may be taken up, ſelecting the fineſt and largeſt, which preſerve in ſand till ſpring; then plant them in the common way, and by the autumn following they will have made proper increaſe, and attain full perfection; when their properties muſt be determined.

It is not improbable, from what has been written on the ſubject in the Tranſactions of the Horticultural Society of London, that much utility and advantage may be derived in the cultivation of the early or proper garden potatoe, from making uſe of new and more early varieties than ſuch as have been uſually employed. Formerly, the early varieties of this root were ſolely gained by accident from the ſeeds of the late ſorts, and conſequently not often produced; as the early ſorts or varieties of this plant were well known to ſeldom or never afford either bloſſoms or ſeeds in the common methods of culture, they being only capable of being increaſed by portions of their tubers or roots. But by having recourſe to ſuch methods of management with them, as tend to prevent the preternaturally early forming of their tubers or roots, it has been found that ſeeds may be readily procured from the moſt early of the beſt early ſorts, the ſeeds of which may, it is ſuggeſted, in ſucceſſive crops, at laſt afford ſtill more early and better varieties, than any which have hitherto been produced. This would be a great and important acquiſition, eſpecially in the garden culture of the potatoe. See POTATOE.

The manner of the cultivation of the potatoe in the preceding year, and the ſtate which it is in from it, would ſeem alſo to have much influence on the produce of the ſucceeding year, as great benefit has, it is ſaid, ariſen from planting ſuch potatoes as had grown late and not been fully maturated in the preceding year. And in the early ſorts it has been found, that the earlineſs likewiſe of the crops, to ſome extent, are dependent upon the ſtate of the varieties; ſo that the ſucceſs of the cultivator in raiſing an early crop of this kind, may be good or bad, according to the mode or manner of the culture, in the preceding year, of the tubers or plants. Such varieties as have the appearance of being expended, worn out, and worthleſs, may alſo be reſtored, in ſome inſtances at leaſt, to their original or primary vigour and importance by attention in this way.

Thus, by preparing proper tubers in the preceding year for planting out crops in the ſucceeding one, great utility may be produced in the garden cultivation of this root, as well as in the field.

In the ſame Tranſactions, in ſpeaking of the preventing of the curl, the able preſident remarks, that the rough and uneven ſurface of the leaf in this plant, which, in exceſs, indicates, and indeed conſtitutes, the diſeaſed ſtate known by the above name, ſeems to exiſt in, and to form an eſſential characteriſtic, of every good variety of the potatoe; as he has never met with a ſingle variety of the perfectly ſmooth poliſhed-leaved kind that poſſeſſed any degree of excellence. And it is endeavoured to be proved, that this rough and crumpled ſtate of the leaf probably originates in the preternaturally inſpiſſated or thickened ſtate of the fluid, in the firm and farinaceous potatoe. Such varieties, however, as have ſmooth and poliſhed leaves, are, it is ſaid, in general, the moſt productive, and grow in the moſt luxuriant manner, which, it is thought, partly ſhews, that the ſmooth leaf is a more perfect and efficient organ than the rough one; the latter indicating, it is ſuppoſed, ſome degree of approximation to diſeaſe.

It is ſtated, that by planting potatoes of an early variety in the ſame ſoil from which a crop of the ſame variety had been taken in the month of July, a ſecond crop was procured. But the tubers produced by thoſe laſt planted, were found to be much more ſoft and watery, when boiled, than others of the ſame variety, and conſequently greatly inferior in value for all culinary purpoſes; they were on that account kept for future planting. It was inferred, on the principles that had been laid down, that the organizable matter theſe contained, being in a leſs firm and concrete ſtate, it would prove more diſpoſeable, and that in the ſucceeding ſeaſon, plants of ſtronger growth, and more ſmooth and perfect foliage, might conſequently be expected. The reſult proved the inference to be every way true: the plants preſented the appearance of a different variety, and afforded a more abundant crop and larger tubers than had ever before been obtained from the ſame variety. This trial was, it is ſaid, confined to a ſingle very early kind, which had previouſly produced partially curled leaves; but, it is ſuppoſed, the ſame method of management will prove equally advantageous with other varieties, which ſhew ſimilar indications of incipient diſeaſe.

If this reaſoning and mode of culture ſhould turn out to be correct and well founded, they may be of great uſe in bettering and promoting the growth of this ſort of valuable root.

By other writers this diſeaſe in the potatoe plant has, however, been ſuppoſed to ariſe in other ways, and to be of a very different kind; and it is ſtated, that Mr. Dickſon, in the Tranſactions of the Caledonian Horticultural Society, conceives it to originate in debility, ariſing from the too great ripeneſs of the tubers, and in the parent plant having too much expended itſelf in affording bloſſoms and ſeeds, as well as tubers. In proof of which, the very curious fact is related, that a cutting taken from the extremity, which is moſt firm and farinaceous, of a long or kidney-ſhaped potatoe, will afford diſeaſed plants, while another cutting taken from the oppoſite end of the ſame potatoe, will produce perfectly healthy plants.

But it is thought by Mr. Knight, that this opinion cannot be acceded to, as it is not to be ſuppoſed, that a plant which is a native of ſuch a climate as the potatoe, can ever be over-ripened in ſo northern a ſituation; beſides, thoſe varieties which never afforded either bloſſoms or ſeeds, have in his garden been quite as ſubject to the diſeaſe as others. Nor is it believed that the buds of the firm farinaceous extremity have greater maturity than thoſe at the contrary end, as thoſe neareſt the parent plant are in reality the oldeſt, the tuber being formed by a branch, which has expanded itſelf in a lateral manner, inſtead of having extended itſelf in a longitudinal direction. Conſequently the buds of it are arranged as they would have been upon the elongated branch; and every tuber, in its incipient ſtate of formation, will extend itſelf into a branch, provided the plant, to which it belongs, be cut off cloſe to the ground, and the current of aſcending ſap be in conſequence diverted into, and through the tubers.

It is however found, by both the above inquirers, that a tuber, or part of one, which is ſoft and aqueous, affords a better plant than one which is firm and farinaceous, or in the mealy ſtate.

It is ſaid, in the corrected Agricultural Survey of Cornwall, that a gardener of Penzance, in that diſtrict, can aſcertain when a potatoe choſen for a ſet will produce the curl; as a healthy potatoe will always, in his opinion, be largeſt, and rounded at its noſe-end, while a diſeaſed potatoe runs ſmaller at its noſe-end than at the tail-end, and will produce the curl, if planted. It is noticed, that the form of the diſeaſed potatoe here deſcribed is very eaſily diſtinguiſhable in the kidney ſort, or in any long-ſhaped potatoe, but not ſo readily, or with ſuch facility, in the round kind; yet it is ſuppoſed to be capable of being diſtinguiſhed by attention, and a little practice, in all.

In regard to ſets, as whole potatoes do not always anſwer well for the purpoſe, and as thoſe of certain large ſizes are better than ſmall ones; the beſt mode of forming them is ſuppoſed to be that of taking off the ſprout or noſe-end, and the umbilical or tail-end of the potatoe, leaving the middle part entirely for the ſet. The worſt mode of cutting the potatoe, in this intention, is, it is ſaid, that of dividing it down the middle, from the noſe to the tail, though a method much too commonly practiſed.

The preparing the ſets beforehand, as in the preceding winter, from the faireſt and beſt potatoes, and placing them in ſuch dry ſituations, as that they may become incruſted with their juice, and thereby bleed leſs before ſprouting, than if freſh cut in the ſpring at the time of planting, is a practice adopted in Ireland with advantage. The ſet is, of courſe, ſtronger, and it puts forth a more vigorous ſhoot ſoon after being planted. The planting of ſmall whole potatoes, or ſets having more than two ſtrong eyes or buds, is with reaſon commonly avoided; and thoſe potatoes with a number of eyes, on what is termed the crown of the potatoe, are invariably rejected, with the ſmall potatoes, both being found to produce languid ſhoots, and a number of ſmall bad potatoes of no value. In all theſe ſtates they are thought to be improper for planting as ſets.

Theſe hints, ſtatements, and concluſions, may ſerve to extend and improve our knowledge of the nature of a diſeaſe which has long been ſo injurious to potatoe crops. See Curl.

Ch. *Cal.* Perianth inferior, of one leaf, in five deep, erect, lanceolate, permanent ſegments. *Cor.* of one petal, bell-ſhaped, gradually dilated upwards, divided into numerous, linear, ſtraight ſegments. *Stam.* Filaments five, thread-ſhaped, very ſhort; anthers ſimple, arrow-ſhaped, pointed, converging, ſhorter than the corolla. *Piſt.* Germen ſuperior, roundiſh; ſtyle thread-ſhaped, about the length of the corolla, permanent; ſtigma obtuſe, notched, downy. *Peric.* Capſule nearly cylindrical, ſlightly curved, obliquely ſtriated, of one cell, opening with five abrupt notched teeth at the ſummit. *Seeds* numerous, minute, pointed, attached to a central, columnar, unconnected *receptacle*.

Eſſ. Ch. Corolla bell-ſhaped, in many linear ſegments. Anthers beaked. Capſule cylindrical, of one cell, with ſeveral teeth at the ſummit.

1. S. *alpina*. Alpine Soldanella. Linn. Sp. Pl. 206. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 49. Jacq. Auſtr. t. 13. Camer. Epit. 254. (S. alpina, major et minor; Cluſ. Hiſt. v. 1. 308, 309. Ger. Em. 838, 839.)—Native of the alps of Auſtria and Switzerland, and the Pyrenean mountains, flowering in ſpring. With us it is uſually reckoned a hardy perennial, but ſucceeds beſt in a pot, ſheltered in a frame in winter. Few, even of its alpine companions, are more ſingularly elegant. The *root* is fibrous. *Stem* none. *Leaves* ſeveral, ſtalked, ſpreading, round, ſmooth, convex, nearly or quite entire; ſomewhat heart-ſhaped at the baſe; paler underneath. *Flower-ſtalks* ſeveral, radical, erect, four or five inches high, ſmooth, each bearing one, two, or three drooping *flowers*, of a delicate purpliſh blue, occaſionally white, with a red *calyx*, and two or three lanceolate *bracteas* at the baſe of the partial ſtalks. *Capſule* near an inch long. *Style* various in length.

SOLDANELLA, in *Gardening*, contains a plant of the low, herbaceous, perennial kind, of which the ſpecies cultivated is the alpine ſoldanella (S. alpina).

In this ſort there is a variety which has all the parts ſmaller; the petiole is ſhorter and more ſlender, and the leaves are not ſo much rounded, but gradually widen from the petiole.

Method of Culture.—This is increaſed by parting the roots in autumn, about September, planting them in pots, or in a cool ſhady ſituation, where the ſoil is of a moiſt loamy kind, being frequently watered when the ſeaſon is dry, and kept from the ſun.

The ſeeds, ſoon after they become ripe, may alſo be ſown in pots or boxes, filled with the above ſort of mould, being placed in the ſhade, and frequently watered. The plants riſe in the ſpring, and in the autumn following ſhould be removed into ſeparate pots, to have the protection of a frame in winter. They ſucceed beſt in a northern aſpect.

Theſe plants afford variety among other potted plants, in different ſituations about the houſe.

SOLDAU, or DZIADORF, in *Geography*, a town of Pruſſia, in the province of Oberland; 100 miles S. of Konigſberg. N. lat. 53° 2′. E. long. 20° 4′.

SOLDER, SODDER, or *Soder*, formed from the French *ſoudure*, of the Latin *ſolidare, to ſtrengthen:* is a metallic compoſition, uſed in ſoldering or joining together other metals.

For this purpoſe, it is required that ſolders melt ſooner than the metal to be ſoldered, that they adhere firmly to its ſurface, and that they approach as near as may be to the metal ſoldered in hardneſs and colour.

The different ſolders are made of gold, ſilver, copper, tin, biſmuth, and lead; uſually obſerving, that in the compoſition there be ſome of the metal to be ſoldered mixed with ſome higher and finer metals.

The ſolder for gold is compoſed of fine gold, with one-fourth or one-half its weight of fine ſilver, accurately mixed together by fuſion, and afterwards beat out into leaves, ſomewhat thinner than card-paper, and rendered as ſoft as poſſible by annealing. For the method of applying it, ſee SOLDERING.

Goldſmiths are ſaid to make four kinds of ſolder; *viz.* ſolder of eight, where, to ſeven parts of ſilver, there is one of braſs or copper; ſolder of ſix, where only a ſixth part is copper; ſolder of four, and ſolder of three. It is the mixture of copper in the ſolder that makes raiſed plate always come cheaper than flat.

As mixtures of gold with a little copper are found to melt with leſs heat than pure gold itſelf, theſe mixtures ſerve as ſolders for gold; two pieces of fine gold are ſoldered by gold that has a ſmall admixture of copper; and gold alloyed with copper is ſoldered by ſuch as is alloyed with more copper: the workmen add a little ſilver as well as copper, and vary the proportions of the two to one another, ſo as to make the colour of the ſolder correſpond, as nearly as may be, to that of the piece. A mixture of gold and copper is alſo a ſolder for fine copper as well as for fine gold.

Gold being particularly diſpoſed to unite with iron, this metal, with a high alloy of copper, proves an excellent ſolder for the finer kinds of ſteel inſtruments.

For larger works in iron and ſteel, copper, or an alloy compoſed of equal parts of tin and iron, is employed.

The ſolder uſed by plumbers is made of two pounds of lead to one of block-tin. Its goodneſs is tried by melting it, and pouring the bigneſs of a crown-piece on a table; for, if good, there will ariſe little, bright, ſhining ſtars in it.

For ſilver, two kinds of ſolder, *viz.* the hard and ſoft, are uſed and applied like the gold ſolder. The hard ſolder is compoſed of equal parts of ſilver and fine braſs, and the ſoft is prepared by fuſing the hard ſolder with $\frac{1}{15}$th its weight of pure zinc. Another ſolder for ſilver may be formed of two parts of fine ſilver and one part of braſs, taking care that theſe are not long kept in fuſion, leſt the braſs fly off in fumes. For coarſer ſilver, a ſolder is prepared by melting four parts of fine ſilver and three of braſs, throwing in a little borax, and pouring it out as ſoon as it is melted.

The ſolder for copper is made like that of the plumbers; only with copper and tin; and for very nice works, inſtead of tin, they ſometimes uſe a quantity of ſilver.

For copper, braſs, and the hard alloys of copper, the beſt hard ſolder, ſays Aikin (Dict.), is compoſed of braſs and zinc, in the proportion of from eight to ſixteen of the former to one of the latter, according to the required hardneſs. The ſoft ſolder is compoſed of three parts of zinc and one of lead, and is applied by means of a common ſoldering iron, made red-hot.

Solder for tin is made of two-thirds of tin and one of lead, or of equal parts of each; but where the work is any thing delicate, as in organ-pipes, where the juncture is ſcarcely diſcernible, it is made of one part of biſmuth, and three parts of pewter.

The pewterers uſe a kind of ſolder made with two parts of tin and one of biſmuth: this compoſition melts with the leaſt heat of any of the ſolders.

The ſolder for tin, pewter, and lead (or the plumber's ſolder), ſays Aikin (ubi ſupra), is of two kinds: the leaſt fuſible is compoſed of equal parts of tin and lead; the more fuſible contains, beſides, biſmuth in various proportions. A very good ſoft ſolder is prepared by melting together ſixteen parts of tin, eight of lead, and four of biſmuth.

Spelter ſolder is made of one part of braſs and two of ſpelter, and is uſed by the braziers and copper-ſmiths for ſoldering braſs, copper, and iron. This ſolder is improved by adding to each ounce of it one pennyweight of ſilver. But as this ſolder does not melt without a conſiderable degree of heat, it cannot be uſed when it is inconvenient to heat the work red-hot; and therefore, in this caſe, copper and braſs are ſoldered with ſilver.

Though ſpelter ſolder be much cheaper than ſilver ſolder, yet workmen in many caſes prefer the latter. And Mr. Boyle informs us, that he has found it run with ſo moderate a heat, as not much to endanger the melting of the delicate parts of the work to be ſoldered; and if well made, this ſilver ſolder will lie even upon the ordinary kind itſelf; and ſo fill up thoſe little cavities that may chance to be left in the firſt operation, which is not eaſily done without a ſolder more eaſily fuſible than the firſt made uſe of. Works Abridged, vol. i. p. 135.

As to iron, it is ſufficient that it be heated red-hot, and the two extremities, in this ſtate, be hammered together. By this means they become incorporated one with the other: when it is ſoldered it is uſually done with braſs; good tough braſs, with borax applied, mixed with water to the conſiſtence of paſte.

The duke of Florence's nail, anciently ſo much admired, as being half iron and half gold, whereas thoſe two metals were deemed irreconcileable, was joined by a kind of ſolder made by Turneiſſer, an ingenious chemiſt of Venice; the ſecret of which was never diſcovered till publiſhed by Tachenius. This ſolder is nothing but a little copper, or cyprus vitriol, put between the gold and the iron. For, naturally, the great acidity of the gold reduces the iron into a ſcoria or ruſt, when the two are applied over one another; but this inconvenience is removed, by the interpoſition of a little copper, be it in the ſmalleſt quantity imaginable. See the next article.

SOLDERING, or **Soddering**, among *Mechanics*, the joining and faſtening together of two pieces of the ſame metal, or of two different metals, by the fuſion and application of ſome metallic compoſition on the extremities of the metals to be joined.

In ſoldering, ſome artifice is neceſſary to make the ſolder and metals adhere. All the metals, except ſilver and gold, upon melting, or before, are covered with droſs: and all the ſolders have ſome of theſe metals in them: this droſs hinders the ſolder and metal from uniting, and it is neceſſary to remove it. This is not performed in every kind of ſoldering by the ſame materials. The plumbers effect this by greaſing the lead, laying on the ſolder, and melting it with a hot iron, and thus the droſs, generated in fuſion, unites with the greaſe, and flows away from the melted metal. The glaziers and tin-men uſe roſin in powder for the ſame purpoſe; for all inflammable ſubſtances that will melt are equally conducive to this uſe. When copper and braſs are ſoldered with pewter, the work is firſt waſhed with a ſolution of ſal ammoniac in water, then heated juſt hot enough to melt the pewter, and the pewter applied to the joint to be ſoldered. In ſoldering that requires a greater heat, borax is uſed.

Thus, in ſoldering gold, and alſo ſilver, take a piece of ſolder of the proper ſize and ſhape, and lay it on the part to be cemented, and ſprinkle it over with pulverized borax; then apply the flame of a blow-pipe, which will cauſe both the borax and ſolder to fuſe, the latter incorporating with, and adhering firmly to, the gold. When the juncture is complete, the piece is left to cool, and the borax is removed by boiling water, or, what is ſtill better, a little dilute ſulphuric or muriatic acid. It is obſerved, that the ſolder will, in this caſe, appear conſiderably paler than the other part, both on account of the ſilver with which it is alloyed, and of the borax, which always lowers the colour of the gold. This defect, however, may be remedied by melting on the ſurface of the ſolder a mixture of two parts of nitre and one of burnt alum, and afterwards waſhing it off with a ſoft bruſh and hot water; by which the natural colour of the gold will be reſtored, and even heightened. Others direct this operation to be performed by joining together the pieces propoſed to be united with fine ſoft iron wire, and touching the joint to be ſoldered with a camel's hair pencil, dipped in borax finely powdered, and well moiſtened with water; and then placing a little ſolder upon the joint, and applying upon it a large piece of charcoal, and, with a blow-pipe and lamp, blowing upon it through the flame, until it melts the ſolder; and thus the work is finiſhed. In order to cleanſe ſilver or gold, after it is ſoldered, make it juſt red-hot, and let it cool; then boil it in alum-water, in an earthen veſſel, and it will be as clean as when new. If it be gold, boil it in urine and ſal ammoniac.

For a method of ſoldering, particularly uſeful to optical and mathematical inſtrument-makers, ſee GRINDING *of Metallic Specula*.

SOLDIDO, a name given to the tamoata.

SOLDIER, a military man, liſted to ſerve a prince or ſtate, in conſideration of a certain daily pay.

The word is formed from the Italian, *ſoldato*, and that from the Latin, *ſolida*, or *ſolidata*, of *ſolidus*, the *ſolde* or *pay;* though Paſquier chooſes to derive it from the old Gauliſh *ſoldoyer*, a ſoldier; and Nicod from *ſoldurius*.

The ſoldier is a perſon who takes pay; the vaſſal is one who is obliged to ſerve at his own expence: the volunteer ſerves at his own expence, and of his own accord.

Du-Cange obſerves, that the ancient ſoldiers were not to be ſhort of five feet and a half; and that this meaſure was called *incoma* or *incomma*.

Every member of a ſociety, capable of bearing arms, is obliged to ſerve and defend the ſtate; and, therefore, ſhould be diſpoſed to take them up, at the firſt order of him who has the power of making war. In England this is the prerogative of the king, for to him belongs the right of granting commiſſions for raiſing troops; but he cannot compel any perſon to enliſt, nor, without the concurrence of the parliament, keep an army on foot. In ancient times, eſpecially in ſmall ſtates, every member, on a declaration of war, was a ſoldier: the whole community took up arms, and followed to the war. Soon after a choice was made, and armies formed of ſelect men, whilſt the reſt of the people purſued their common occupations. At preſent the uſe of regular troops is almoſt every where adopted, eſpecially in powerful ſtates. The public authority raiſes ſoldiers, diſtributes them into different bodies, under the command of generals and other officers, and keeps them on foot as long as it thinks neceſſary. As every citizen or ſubject is obliged to ſerve the ſtate, the ſovereign has a right, in caſe of neceſſity, to enliſt whom he pleaſes; but he ſhould chooſe only ſuch as are proper for the occupation of war: and it is highly proper to take, as far as poſſible, only volunteers, who enliſt chearfully without compulſion. See ENLISTING, IMPRESSING, and VOLUNTEERS.

No perſon is naturally exempt from taking up arms in defence of the ſtate; the obligation of every member of the ſociety being the ſame. Thoſe only are excepted, who are incapable of handling arms, and ſupporting the fatigues of war. This is the reaſon why old men, children, and women, are excepted. Nevertheleſs, unleſs government is compelled by neceſſity, it ſhould exempt from military ſervice all who are employed in ſtations uſeful or neceſſary to ſociety. Magiſtrates are, therefore, uſually excepted; their whole time not being too much for the adminiſtration of juſtice, and the maintenance of order. The clergy, ſays Vattel, cannot naturally, and by any right, arrogate to themſelves a particular exemption. To defend one's country is an action not unworthy of the moſt ſacred hands. However, the reaſons alleged in favour of magiſtrates may be urged alſo in behalf of that part of the clergy who are truly uſeful; ſuch as teach religion, govern the church, and celebrate the public worſhip. But as for thoſe immenſe multitudes of uſeleſs religious, who, under pretence of dedicating themſelves to God, in effect ſpend their lives in an effeminate idleneſs, they have no right to claim a privilege that is pernicious to the ſtate; and whilſt the prince exempts them from military ſervice, he injures the other members of the community, by throwing on them the whole burden. "I do not pretend," ſays Vattel, "to adviſe a prince to fill his armies with monks, but gradually to diminiſh a uſeleſs claſs of men, by taking from it injurious and ill-grounded privileges." There is another claſs of idle perſons, the exemption of whom is ſtill more culpable; that uſeleſs claſs of footmen, who fill the houſes of the great and wealthy: a claſs who by their calling corrupt themſelves, by diſplaying the luxury of their maſter.

Among the Romans, while all the people ſerved alternately in war, their ſervice was gratuitous; but when a choice is made, and ſtanding armies are formed, the ſtate is to pay them; no man owing more than his quota of the public ſervice: and if the ordinary revenues are not ſufficient, it muſt be provided for by impoſts. It is juſt that they who do not ſerve ſhould pay their defenders. When the ſoldier is not in the field, there is a neceſſity of quartering him; and this burden naturally falls on houſekeepers: but as it is attended with many inconveniencies to the people, it becomes a good prince, or a wiſe and equitable government, to eaſe them of it as far as poſſible. Moreover, the aſylums prepared for ſoldiers and reduced officers, who are grown old in the ſervice, or whom fatigues or the enemy have rendered incapable of providing ſubſiſtence for themſelves, may be conſidered as part of the military pay. The eaſe of theſe unfortunate victims of war is the indiſpenſible duty of every ſtate, in proportion to its ability. It is contrary, not only to humanity, but to the ſtricteſt juſtice, that generous citizens, heroes who have ſhed their blood for the ſafety of their country, ſhould be left to periſh with want, or unworthily forced to beg for ſubſiſtence.

Mercenary ſoldiers are foreigners voluntarily engaging to ſerve the ſtate for money, or a ſtipulated pay. As they owe no ſervice to a ſovereign, whoſe ſubjects they are not, the proſpect of advantage is their ſole motive. It has been a queſtion, however, whether the profeſſion of a mercenary ſoldier be lawful, or not? or whether individuals may for money, or any other reward, engage to ſerve a foreign prince in his wars? This queſtion, ſays Vattel, does not to me appear very difficult to be ſolved. They who enter into ſuch engagements, without the expreſs or tacit conſent of their ſovereigns, offend againſt their duty as ſubjects. But if their ſovereign leaves them at liberty to follow their inclination for a military life, they are abſolutely free. Now, every free man may join himſelf to whatever ſociety he pleaſes, and which to him appears moſt advantageous. He may make its cauſe his own, and eſpouſe its quarrels. He becomes in ſome meaſure, at leaſt for a time, a member of the ſtate in the ſervice of which he engages: and as an officer is commonly at liberty to quit the ſervice when he thinks proper, and the ſoldier at the term of his engagement; if, therefore, this ſtate embark in a war, manifeſtly unjuſt, the foreigners may quit its ſervice. And this mercenary ſoldier having now learnt the art of war, has rendered himſelf capable of ſerving his country, whenever it requires his aſſiſtance. The laſt conſideration will furniſh us with an anſwer to a queſtion propoſed on this head: whether the ſovereign may, with equity and decency, permit his ſubjects to ſerve foreign powers indiſcriminately for money? He may, becauſe his ſubjects will by this means learn an art, the thorough knowledge of which is both uſeful and neceſſary. The tranquillity, the profound peace, which Switzerland has ſo long enjoyed, in the midſt of all the commotions and wars which have agitated Europe; this long repoſe, it is ſaid, would ſoon become fatal to it, did not the citizens, by ſerving foreign princes, qualify themſelves for the operations of war, and ſupport their martial ſpirit.

Mercenary ſoldiers engage themſelves, and enliſt voluntarily. The ſovereign has no right to compel foreigners;

he is not even to make uſe of artifice or ſurpriſe, for inducing them to engage in a contract, which, like all others, ſhould be founded on candour and probity.

As the right of levying ſoldiers belongs ſolely to the nation, ſo no perſon is to enliſt ſoldiers in a foreign country, without the permiſſion of the ſovereign; and even with this permiſſion, none but volunteers are to be enliſted: for the ſervice of their country is out of the queſtion here, and no ſovereign has a right to give or ſell his ſubjects to another. They who undertake to enliſt ſoldiers in a foreign country, without the ſovereign's permiſſion; and, in general, whoever alienates the ſubjects of another, violates one of the moſt ſacred rights both of the prince and the ſtate. It is the crime diſtinguiſhed by the name of *plagiat*, or manſtealing, and accordingly is puniſhed with the utmoſt ſeverity in every policied ſtate.

All ſoldiers, natives or foreigners, are to take an oath to act faithfully, and not deſert the ſervice. This is no more than what they are already obliged to, the one as ſubjects, the other by their engagement; but their fidelity is of ſo great importance to the ſtate, that too many precautions cannot be taken for rendering it ſecure. Deſerters ſhould be ſeverely puniſhed, and the ſovereign, where he judges it neceſſary, may inflict capital puniſhment on them. The emiſſaries, who ſolicit them to deſert, are far more guilty than the recruiters above mentioned.

Good order and ſubordination, ſo uſeful in all places, are no where ſo neceſſary as in an army. The ſovereign ſhould exactly ſpecify and determine the functions, duties, and rights of military perſons, as ſoldiers, officers, commanders of parties, and generals. He ſhould regulate and fix the authority of commanders of all degrees, the puniſhments to be inflicted on offences, the form of trials, &c. The laws and orders relative to theſe ſeveral particulars form the military code.

Theſe regulations, the particular end of which is to maintain order in the troops, and to render them capable of performing the beſt ſervice, conſtitute what is called military diſcipline.

Judge Blackſtone obſerves, that in a land of liberty it is extremely dangerous to make a diſtinct order of the profeſſion of arms. In abſolute monarchies this is neceſſary for the ſafety of the prince, and ariſes from the main principle of their conſtitution, which is that of governing by fear; but in free ſtates, the profeſſion of a ſoldier, taken ſingly and merely as a profeſſion, is juſtly an object of jealouſy. In theſe no man ſhould take up arms but with a view to defend his country and its laws: he puts not off the citizen when he enters the camp; but it is becauſe he is a citizen, and would wiſh to continue ſo, that he makes himſelf for a while a ſoldier. The laws, therefore, and conſtitution of theſe kingdoms, know no ſuch ſtate as that of a perpetual ſtanding ſoldier, bred up to no other profeſſion than that of war; and it was not till the reign of Henry VII. that the kings of England had ſo much as a guard about their perſons.

The preſent regulations concerning the regular military force of our country, as contradiſtinguiſhed from the militia, &c. and for regulating the royal marine forces when on ſhore, are chiefly contained in the yearly acts againſt mutiny and deſertion. Theſe comprehend the articles of war, enliſting of ſoldiers, including foreign ſoldiers, the number of whom allowed to be at one time in the united kingdom is extended by 46 Geo. III. c. 23. to 16,000, muſter, the proviſion of carriages, billeting of ſoldiers, or quartering them by conſtables or other magiſtrates of cities, towns, villages, &c. in livery ſtables, ale-houſes, victualling houſes, the houſes of ſellers of wine by retail, and all houſes of perſons ſelling brandy, ſtrong waters, cyder, or metheglin, by retail; but in no private houſes whatſoever; and the rates of ſubſiſtence to be paid to innkeepers, &c. for ſoldiers' quarters; the removal of ſoldiers in times of election of members of parliament; the mode of apprehending and puniſhing of deſerters; maintenance and ſetting up trades after their diſcharge; the probate of their wills, &c. &c. Moſt of theſe particulars occur under their reſpective heads; and for others our limits require us to refer to the acts themſelves.

As ſoldiers, by the annual act of mutiny, are put in a worſe condition than any other ſubjects, ſo, by the humanity of our ſtanding laws, they are in ſome caſes put in a much better. By ſtat. 43 Eliz. cap. 3. a weekly allowance is to be raiſed in every county for the relief of ſoldiers that are ſick, hurt, and maimed; and beſides, the royal hoſpital at Chelſea is eſtabliſhed for ſuch as are worn out in their duty. Moreover, officers and ſoldiers, that have been in the king's ſervice, are by ſeveral ſtatutes, enacted at the cloſe of ſeveral wars, at liberty to uſe any trade or occupation they are fit for in any town in the kingdom, (except the two univerſities,) notwithſtanding any ſtatute, cuſtom, or charter to the contrary. And ſoldiers in actual military ſervice, may make noncupative wills, and diſpoſe of their goods, wages, and other perſonal chattels, without thoſe forms, ſolemnities, and expences, which the law requires in other caſes. Blackſt. Comm. book i. cap. 13.

The profits attending the profeſſion of a ſoldier, among the Romans, were very conſiderable. 1. Booty and plunder, with which they frequently returned home loaded, eſpecially after taking any cities or towns; for theſe were generally given up to be plundered. 2. The ſubdued countries, which were often divided among the ſoldiers. 3. Their pay. 4. Clothes. 5. Proviſions. 6. Farms and houſes in provinces were alſo given them. 7. Many privileges and immunities, as that none could touch his goods in his abſence in the camp. 8. Legacies, which the emperors left to be diſtributed among them. 9. Donatives. 10. Promotions to military honours lay open to every brave man, though of the meaneſt birth.

Not only humanity but intereſt require that great care ſhould be taken of the health of ſoldiers. Much inſtruction may be drawn for this purpoſe from Dr. Pringle's excellent treatiſe, called "Obſervations on the Diſeaſes of the Army." He there remarks, that the circumſtances of ſoldiers in time of war differ from thoſe of other people, in that they are more expoſed to the injuries of the weather, and always crowded together, whether in camp, barracks, or hoſpitals: wherefore the moſt general diviſion of theſe diſtempers may be into ſuch as ariſe from the intemperature of the weather, and thoſe from infection.

Military diſeaſes depending on the weather, are reducible to two ſorts, *viz.* to thoſe of ſummer, and to thoſe of winter. However, as expoſitions to cold are unavoidable upon the firſt encampment, as alſo for ſome time before the army uſually goes into winter-quarters, the winter diſorders, beginning about the end of autumn, will not entirely ceaſe before the ſummer is well advanced; and, on the other hand, as the heats of ſummer and damps of autumn diſpoſe the body to ſickneſs, the camp-diſtempers are never quite over with the campaign, but continue ſome time after the troops retire into winter-quarters.

The ſummer diſeaſes are all of a bilious or putrid nature, as thoſe of winter are inflammatory. See FEVER, and the articles referred to under that ſubject.

SOLDIERS, *Exerciſe of.* See EXERCISE.

SOLDIERS, *Liſting* or *Enliſting of.* See LISTING.

Soldiers, *Puniſhment of*. See *Military* Execution.

For other particulars relating to ſoldiers, ſee Deserter, *Royal* Hospital, *Camp* Hospitals, Court-*Martial*, Martial *Law*, Mutiny, &c.

Soldiers, *Band of*. See Band.

Soldiers, *Freſh-water*, in *Botany*, a name given in ſeveral parts of England to the ſtratiotes, a diſtinct genus of plants, called by Boerhaave *aloides*.

Soldier-*Wood*. See Mimosa.

Soldier's *Gut*, in *Geography*, a cove on the north-eaſt coaſt of the iſland of St. Chriſtopher.

SOLDIN, a town of Brandenburg, the capital of a circle, and formerly the capital of the New Mark, ſituated on a lake of the ſame name, about ſix miles long, noted for its lampreys. The town contains about 200 houſes, and two churches, and has ſome manufactures of cloth; 32 miles N. of Francfort on the Oder. N. lat. 53° 2′. E. long. 14° 59′.

SOLDO, in *Commerce*, a money of account and copper coin in Italy. Ferrara keeps accounts in lire of 20 ſoldi, or 240 denari correnti. The lira alſo contains 2 giuli or paoli; and the ſoldo, 6 quattrini. The ſcudo di Cambio is reckoned at 4 lire, or 80 ſoldi. At Florence, accounts are kept in ſcudo d'oro, ducati, or lire; each of theſe is divided into 20 ſoldi, or 240 denari, and diſtinguiſhed by the names of ſoldi d'oro, ſoldi di ducato, ſoldi di lira; alſo in paoli of $13\frac{1}{3}$ ſoldi di lira. Accounts of certain ſales of goods are likewiſe kept in Pezze da otto reali, or livornine of $5\frac{3}{4}$ lire, which are likewiſe divided into 20 ſoldi, or 240 denari di Pezza. The copper coins at Florence are ſoldi, dueti or pieces of quattrini, ſingle quattrini, and denari or piccioli. At Bologna, accounts are kept in lire of 20 ſoldi; the ſoldo, alſo called Bajocco or Bolognino, is divided into 12 denari, or 5 quattrini. At Rome, the ſcudo di ſtampa d'oro is divided into 20 ſoldi, or 240 denari. The coins at Bologna are of the ſame denomination, weight, and value, as thoſe at Rome. The bolognini in ſilver is a ſingle ſoldi; the copper ſoldi is its half, and quattrini the fifth part of a ſoldo. Kelly's Cambiſt.

SOLDURII, in *Antiquity*, a kind of military clients, or retainers to the great men in Gaul, particularly in Aquitania, mentioned by Cæſar.

The ſoldurii were people that ſhared all the good and ill fortune of their patrons; to whom, if any diſaſter happened, they either underwent the very ſame, or killed themſelves: and Cæſar aſſures us, that no one had ever been known to refuſe the alternative. Lib. iii. de Bell. Gall.

Vigenere takes them to have been more than common ſoldiers; and even gentlemen in penſion, or appointment. Athenæus calls them συναποθνησκοντες, *q. d.* dying together, or with their maſters.

SOLE, in *Geography*, a town of Norway; 6 miles S. of Stavanger.

Sole, in *Ship-Building*, a ſort of lining, to prevent wearing or tearing away the main part to which it may be attached; as to the rudder, bilgeways, &c.

Sole is alſo a name ſometimes given to the lower ſide of a gun-port, which, however, is more properly called the port-ſill.

Sole *of a Horſe*, that plate of horn which, encompaſſing the fleſhy ſole, covers the whole bottom of the foot. The ſole ought to be thick and ſtrong, and the ſhoe of a horſe ſo ſet upon the hoof as not to bear upon it, for otherwiſe the ſole would be hurt, and not only make the horſe lame, but deſtroy the fleſh that ſeparates it from the coffin-bone. It has been an abſurd practice with ſome to take out the ſole. It is done without touching the outſide of the hoof, as taking off the cruſt makes a *hoof-caſt*. And a horſe that has been unſoled, it is ſaid, will recover in a few weeks. But this cuſtom of *drawing* horſes' ſoles, in order to relieve the inflammation of the part, and to promote a free perſpiration, is not in the leaſt beneficial, as it leaves ſuch a weakneſs and tenderneſs behind, that the poor creatures moſtly ever afterwards labour under an incurable lameneſs. And La Foſſe, though he has recommended the practice, has not produced a ſingle inſtance of its ſucceſs. In lieu, therefore, of tearing the ſole up by the roots, Mr. Wood adviſes the following method; in the firſt place, to take off from the tenſion of the veſſels and leſſen the inflammation, to draw away blood at the toe and above the hoof; after which, a poultice, compoſed as below, may be applied. This conſiſts of linſeed boiled in water to a pulp, then adding gooſe-greaſe, tar, and cow-dung to it; boiling them all together to the proper conſiſtence.

The compoſition may be put to the foot, and all round the hoof; and a cold charge applied above the coronet. Where there is no great inflammation, the addition of a little ſoap to the poultice, may aſſiſt much in removing any coagulation of blood in that quarter.

When the foot is ſhaped like the back part of an oyſter-ſhell, and the ſole higher than the hoof, ſo that the whole foot is quite filled up on the lower part, it is called a *crowned ſole*.

Sole *Corporation*. See Corporation.

SOLEA, in *Geography*, a town of Italy, in the department of Panaro; 8 miles N. of Modena.

Solea, or *Soli*, a town of the iſland of Cyprus, formerly the ſee of a biſhop, and in more ancient times called "Epea;" 30 miles N.N.E. of Baffa.

Solea, in *Ichthyology*, the *ſole-fiſh*, a well-known fiſh, and much eſteemed at table. See Soal.

SOLEÆ, among the Romans, were a kind of ſandals or ſlippers, which covered only the ſole of the feet, and were bound on with thongs of leather; inſtead of which the women, and effeminate perſons of the other ſex, tied them on with purple-coloured ribbands, or ſuch as were variouſly adorned with gold and ſilver.

SOLEBAY, in *Geography*. See Southwold.

SOLEBURY, a townſhip of Pennſylvania, in the county of Bucks, containing 1669 inhabitants; 30 miles N. of Philadelphia.

SOLECISM, Soloecismus, in *Grammar*, a groſs impropriety in ſpeech, contrary to the uſe of language, and the rules of grammar, either in reſpect of declenſion, conjugation, or ſyntax. See Purity.

The word is Greek, σολοικισμος, derived from the *Soli*, a people of Attica, who, being tranſplanted to Cilicia, loſt the purity of their ancient tongue, and became ridiculous to the Athenians for their improprieties in it.

An actor on the Roman theatre having made a falſe geſture, the audience immediately cried out, he had committed a ſoleciſm with his hand.

Cicero, ad Herenn. lib. iv. cap. 12. diſtinguiſhes in the following manner between *barbariſm* and *ſoleciſm*. "Latinitas eſt quæ ſermonem purum conſervat, ab omni vitio remotum. Vitia in ſermone, quominus is latinus ſit, duo poſſunt eſſe; ſoleciſmus et barbariſmus. Soleciſmus eſt, cum verbis plurimis conſequens verbum ſuperiori non accommodatur. Barbariſmus eſt, cum verbum aliquod vitioſe effertur."

Soleciſm is accounted by grammarians a much greater fault than barbariſm, (ſee Purity,) as it diſplays a greater ignorance of the fundamental rules of the language. However, when ſoleciſms are not very glaring, where they do not darken the ſenſe, or ſuggeſt ſome ridiculous idea, the rhetorician regards them as much more excuſable than barbariſms; becauſe the former is accounted ſolely the effect of negligence, the latter of affectation. Negligence in expreſſion, often the conſequence of a noble ardour in regard to the ſentiments, is, at the worſt, a venial treſpaſs; ſometimes it is not even without energy; affectation is always a deadly ſin againſt the laws of rhetoric. It ought alſo to be obſerved, that in the article of ſoleciſms, much greater indulgence is given to the ſpeaker than to the writer; and to the writer, who propoſes to perſuade or move, greater allowances are made, than to him who propoſes barely to inſtruct or pleaſe. The more vehemence is required by the nature of the ſubject, the leſs correctneſs is exacted in the manner of treating it. Nay, a remarkable deficiency in this reſpect is not nearly ſo prejudicial to the ſcope of the orator, as a ſcrupulous accuracy, which bears in it the ſymptoms of ſtudy and art. Æſchines is ſaid to have remarked, that the orations of his rival and antagoniſt, Demoſthenes, ſmelled of the lamp, thereby intimating that their ſtyle and compoſition were too elaborate. If this remark be juſt, it conveys the greateſt cenſure that was ever paſſed on that eminent orator. But, as the intermediate degrees between the two extremes are innumerable, both doubtleſs ought to be avoided. Grammatical inaccuracies ought to be avoided by a writer, for two reaſons; one is, that a reader will much ſooner diſcover them than a hearer, however attentive he may be; the other is, as writing implies more leiſure and greater coolneſs than is implied in ſpeaking, defects of this kind, when diſcovered in the former, will be leſs excuſed than they would be in the latter. To enumerate all the kinds of ſoleciſm to which writers and ſpeakers are ſubject, would be both an uſeleſs and endleſs taſk. The tranſgreſſion of any of the rules of ſyntax is a ſoleciſm; and almoſt every rule may be tranſgreſſed in a variety of ways. Some of the more flagrant ſoleciſms are thoſe which betray an ignorance of the rudiments of the tongue; and others, which are more the effects of inattention, may be diſtinguiſhed by the ſofter name of inaccuracies. For examples of both kinds we refer to Lowth, Prieſtley, Murray, and other grammarians. See alſo Campbell's Philoſophy of Rhetoric, vol. i. b. 2. ch. 3.

SOLEDA, in *Geography,* a town of the iſland of Cuba; 56 miles S.S.E. of Havanna.

SOLEFTA, a town of Sweden, in Angermanland; 40 miles N.N.W. of Hernoſand.

SOLEIL. *Ombre de Soleil.* See OMBRE.

SOLEIL *de Mer*, in *Ichthyology*, a name given by the French writers, and by Rondeletius, to a peculiar ſpecies of ſtarfiſh, of a ſmall ſize, the legs of which reſemble very much the tails of lizards, and are very brittle.

Geſner deſcribes alſo a ſpecies under the name of the ſea-moon, *luna marina,* which, he ſays, is remarkably fragile, and which, from what elſe he has ſaid of it in its deſcription, appears alſo to be the ſame creature. The great character, however, of the creature's legs reſembling, both in colour and figure, the end of the common brown land-newt's tail, is ſo expreſſive, that it cannot but be always known by it.

Theſe rays are ſo extremely friable, that it is ſcarcely poſſible to touch them without their breaking, and they are not beſet with points in the manner of the common rays of the creatures of this kind.

The other rays of ſtar-fiſhes being furniſhed with many hundred legs, and theſe wanting them entirely, it follows, that in this ſpecies the rays themſelves muſt ſupply the place of legs, and aſſiſt the creature in walking; and thence its manner of walking muſt neceſſarily be different from that of any other kind. Theſe rays are five in number, and are inſerted very near the mouth of the creature, which is always placed in the centre of the ſtar: the part where this aperture is ſituated, and which may be called the body of the animal, is of a roundiſh figure; the diameter of it is about a third part of the length of the rays; its under ſurface is flat, and its upper convex; and it is covered, both above and below, with ſcales, but they are arranged in different manners.

The common habitations of the ſea-ſtars, on the rough ſhores of the ſea, is no place for theſe tender creatures, every daſh of a wave againſt a ſtone, if they were in the way, would break off their limbs; they have the caution, therefore, to fix their reſidence only in calm places, and where the ſhore is covered entirely with a deep ſmooth ſand. When the water has forſaken them, they are often ſeen walking ſlowly on the ſhore; and in this caſe they uſe their rays as ſo many legs. As they divide the body of the fiſh into two equal parts, there is no ray before or behind any where, ſo that the creature goes with equal eaſe to any ſide that it likes. The beſt motion they are able to make is, however, very ſlow, and the ground on which they march ought to be very even; for if they attempt to haſten their pace, or if they find any thing uneven in their paſſage, one or more of their legs uſually breaks; and this is the reaſon why this ſpecies is ſeldom found with its rays perfect. They never bury themſelves deep in the ſand, but juſt get under it, ſo as to be covered; and this they do by advancing two of the rays together, and burrowing carefully with them, and then following them with the reſt of the rays and the body. Mem. Acad. Par. 1712.

SOLEISSEL, JAMES DE, in *Biography*, a celebrated maſter of horſemanſhip, was born in 1617, in the province of Forez. He was educated among the Jeſuits, but followed, during his ſtudies, a propenſity which he had felt when very young, of attending to the manege, with which, when he arrived at man's eſtate, he joined the ſtudy of the diſeaſes of horſes. When he had made himſelf tolerably perfect in both branches of the ſcience, he commenced teacher of horſemanſhip to the young nobleſſe of his province. The reputation which he ſoon acquired cauſed him to be invited to aſſiſt in the academy for the manege in Paris, where he publiſhed a work, entitled "Le Parfait Marechal," which became very popular, and was tranſlated into ſeveral languages. He was likewiſe author of a treatiſe entitled "Le Marechal methodique," and of a Dictionary of the terms of horſemanſhip. He was a man of a very reſpectable private character, and poſſeſſed all the accompliſhments that were neceſſary to his profeſſion. He died in 1680.

SOLEK, in *Geography*, a town of Auſtrian Poland, in the palatinate of Sandomirs; 30 miles N. of Sandomirs.

SOLEMCO, a town of Hungary; 13 miles E.N.E. of Gros Wardein.

SOLEMN, SOLENNIS, ſomething performed with much pomp, ceremony, and expence. Thus we ſay, ſolemn feaſts, ſolemn funerals, ſolemn games, &c.

SOLEMN, in *Law*, ſignifies ſomething authentic, or that is clothed in all its formalities.

SOLEMN *Acceptance*. See ACCEPTANCE.

SOLEMN *Teſtament*, in the *Civil Law*, is to be atteſted by ſeven perſons, and ſealed with their ſeals.

SOLEMN *Marriage*, is that performed in one's own pariſh-church, after publication of the banns, and in preſence of witneſſes.

SOLEN, or *Razor-Sheath*, in *Natural Hiſtory*, a genus of the Vermes Teſtacea claſs and order, of which the generic character is as follows. The animal is an aſcidia; its ſhield is bivalve, oblong and open at both ends; the hinge has a ſubulate reflected tooth; it is often double, and not inſerted in the oppoſite valve. It had its name, *ſolen*, from the Greek, in which language that word expreſſes a pipe or tube; this fiſh, when the ſhells are cloſed, very aptly reſembling a tube. The Latin writers have called it *unguis*, from its reſemblance in colour and conſiſtence to the human nail. The common people in many parts of France call it *coutelier*, and in Italy it is commonly called *cannolichio*. (See SHELLS.) There are twenty-three ſpecies enumerated by Gmelin, which are as follow.

Species.

* VAGINA. The ſpecific character of this is, that the ſhell is linear, ſtraight, roundiſh, one end emarginated; the hinge is marked with a ſingle oppoſite tooth in each valve. There is a variety that inhabits the European and Indian ſeas: it is ſix or ſeven inches broad, and only one inch long. The ſhell is yellowiſh, divided diagonally into two triangles, one of which is ſtriate longitudinally, the other tranſverſely, and marked with curved bands. This ſpecies, and all the others that are found in this genus belonging to this country, are figured by Barbut, Liſter, Donovan, and other naturaliſts.

* SILIQUA. The ſhell of this ſpecies is linear, and ſtraight; it has one hinge, which is two-toothed. There is a variety with roſy lunules. The former is found in moſt European ſeas, and on our own coaſts. The latter is to be met with in the Indian ſeas. It is ſeven or eight inches broad, and not more than one and a half inch long. The ſhell is equally broad and compreſſed, with a double tooth at the hinge, receiving another oppoſite, and on one ſide there is another ſharp tooth directed downwards: the colour is of an olive-brown, with a limpid aſh-coloured mark dividing the ſhells diagonally: one part is ſtriate longitudinally, the other tranſverſely.

* ENSIS. Shell linear, a little bowed, like a ſcymitar: it has one hinge, which is two-toothed. It inhabits European ſeas. The ſhell is coloured, and marked like that of the ſiliqua; it is rounded at both ends; the two teeth of one valve are inſerted into a triangular hollow of the other.

* PELLUCIDUS. Shell ſub-arched, ſub-oval, pellucid; one hinge two-toothed. This is found on the ſhores of Angleſea; the ſhell is thin and pellucid, about an inch broad, with a double ſharp tooth in one valve, receiving a ſingle one from the oppoſite, with a proceſs in each ſhell pointing towards the cartilage of the hinge.

* LEGUMEN. Shell linear, oval, ſtraight; hinges placed in the middle, and two-toothed; one of them bifid. It is found in the European and the Atlantic ſeas; is two inches and a half broad. The ſhell is ſub-pellucid, radiate, from the hinge to the margin; it is rounded at both ends.

* CULTELLUS. The ſhell of this ſpecies is ſhaped ſomething like a kidney, with a ſingle tooth in one valve and two in the other. It inhabits European and Indian ſeas, and is more than two inches broad. The ſhell is fragile, covered with a rough cuticle, under which it is dirty-white, with tawny marks; both ends are rounded.

RADIATUS. Shell oval, ſtraight and ſmooth, with a tranſverſe depreſſed rib growing on one ſide. This is found in India, and is very thin and brittle. The ſhell is of a violet colour, with four tranſverſe white rays, growing larger towards the thinner margin; the depreſſed rib running nearly the length of the ſhell; the hinge is callous on each ſide; both valves are two-toothed.

STRIGILATUS. Shell oval, obliquely ſtriate. There is a variety which inhabits the Mediterranean, Atlantic, and Indian ſeas. The ſhell is roſy, with two white rays, ſtrong and ventricoſe; the hinge is a little prominent at the margin, with a thin reflected tooth.

ANATINUS. The ſhell of this is ovate, membranaceous, and hairy, with a falcate rib at the hinge. It inhabits the Indian ocean, on a ſandy bottom. The ſhell is pellucid, white, thin, like paper; one end rounded and cloſed, the other gaping, like the beak of a bird: there is a tooth in each valve reſembling an ear-picker.

MACHA. Shell oval, oblong, truncate before; one hinge is two-toothed. It is found in the Pacific ocean. It is about ſix or ſeven inches long; in colour it is brown, varied with blue; it produces pearl.

BULLATUS. Shell roundiſh, inflated, ſub-ſtriate; the fore-part is gaping, in conſequence of its crenatures. This is found in the American and Indian ſeas; brittle, white ſpotted or clouded with purple, longitudinally ſtriate, ſub-pellucid; hinge with a ſingle tooth, marginal ones remote, compreſſed, and inſerted in a hollow of the other valve.

MINUTUS. Shell oval, angles of the valves ſerrate. It is found in the northern parts of Europe, among zoophytes; is the ſize of a cucumber-ſeed; longitudinally ſtriate, truncate at the top, with acute ſerrate ridges, diverging from the hinge towards the top.

VIRENS. The ſhell of this is ovate-oblong, with tumid boſſes. It inhabits Java; is very brittle, diaphanous, white, outwardly greeniſh, valves unequal, reſembling in its ſhape the Mya pictorum; the tip and baſe hardly cloſed, with two approximate teeth in one hinge, and none in the oppoſite.

DIPHOS. Shell oval, ſtraight, ſmooth, with prominent membranes. It inhabits the Indian ocean, and reſembles the S. radiatus. It is two inches and a half long, and five broad; covered with a greeniſh cuticle, under which it is violet, with numerous rays; two of theſe are more diſtinct. The hinge has two teeth in one valve, and one in another.

MINIMUS. Shell linear-oval, ſtraight; the hinges are lateral and two-toothed; one of them is bifid. It inhabits Tranquebar; reſembles the S. legumen, but is much leſs; the cuticle is yellowiſh, under which it is clear white; the inner rib runs down the whole ſhell.

MAXIMUS. Shell linear, oval, ſtraight, with arched ſtriæ; hinges lateral, two-toothed. It inhabits the ſhores of Nicobar; it is a very rare ſpecies. The ſhell is thin and pellucid, white, covered with a yellowiſh cuticle; it is four inches broad, one and a half long, gaping at both ends; the teeth of the hinge not receiving one another.

COARCTATUS. The ſhell of this is tranſverſely wrinkled, contracted in the middle, rounded at both ends; hinge in the middle, with ſometimes one, and ſometimes two teeth in either valve. This is found on the ſhores of Nicobar, is about three-fourths of an inch long, and two and a half broad. The ſhell is of a dirty white, and gaping at both ends.

ROSEUS. Shell roſy, equivalve; the tooth of the hinge is ſub-bifid, and inſerted in a hollow of the oppoſite valve. It inhabits the Red ſea, reſembles the Telina radiata, but is open at both ends.

SANGUINOLENTUS. Shell oval, quite ſmooth; the hinge is callous, and two-toothed. It inhabits Jamaica; the beaks are roſy without and within.

STRIATUS. Shell equivalve, tranſverſely ſtriate; hinge with a ſingle tooth. It is alſo found near the ſhores of Nicobar,

Nicobar, and is middle-ſized. The ſhell is thin, roſy, with white rays.

Occidens. The ſhell of this ſpecies is tranſverſely ſtriate, ſmooth at the protuberant parts, radiate with white and reddiſh; both the hinges are two-toothed, with a hollow in the middle. Its reſidence is not known. The ſhell is marked with white and reddiſh ſpots ſcattered about; is more than four inches broad, and two long; both ends are gaping; the hinge is lateral.

* Crispus. The ſhell, in this ſpecies, is partly ſmooth, partly rough with undulate crimped lines; the hinge has a long narrow tooth. It is found in the river Tees, and reſembles the S. anatinus, though it is thought by ſome naturaliſts not to be a diſtinct ſpecies.

Spengleri. Protuberances or beaks of the ſhell two-parted; primary tooth of the hinge rounded, acceſſory ones long and narrow; one of them is curved. The ſhell is hardly an inch long, but two and a half broad; it is rounded at both ends.

Rondeletius obſerves, that there are, among the ſolens of the ſame ſpecies, males and females, which are eaſily diſtinguiſhable from one another; and that the females are larger, have no variegations on the ſhells, and are much better taſted than the males. Rumphius has deſcribed a very remarkable ſpecies of ſolen, which always remains buried in ſand, and which is not properly a bivalve, conſiſting only of one piece, though of the ſhape of the ſolen; he calls this *ſolen arenarius*. Liſter has called the crooked ſpecies *ſolènes curvi*, and ſome call them the *ſcymitar* ſolens.

We have ſeveral ſpecies of the ſtraight ſolens, though but few of the crooked ones.

Of the crooked ſolens, two are the only known ſpecies. 1. The ſcymitar ſolen. 2. The *ſolen arenarius*, always found in ſand.

The ſhell of this fiſh is compoſed of two pieces, which are the two halves of a hollowed cylinder, with an elliptic baſe, divided in a longitudinal direction. Theſe two pieces are faſtened together near one end by a ligament, like that which joins the ſhells of the muſcle or the oyſter. From the place where this ligament is fixed, quite to the other end of the ſhell, there is a membrane faſtened to each edge of the ſhell, and this increaſes in breadth in proportion to its diſtance from the place of its origin; ſo that, viewed externally, it forms a ſort of iſoſceles triangle, the baſe of which was about two lines in breadth. The colour and conſiſtence of this membrane give it very much the appearance of a piece of parchment; it has a conſiderable ſpring in it, and ſerves on occaſion to open, or draw together, the two ſides of the ſhell.

There is another membrane, of the ſame kind with this, faſtened to the other ſide of the fiſh, there adhering to each ſhell, but this is of an equal breadth all the way down: this ſerves alſo to ſhut or open the edges of the ſhell. When the ſolen ſhuts its ſhell, it folds itſelf into ſeveral longitudinal wrinkles, which open again when the ſides of the ſhells ſeparate.

Hence it is to be obſerved, that though this ſhell has a power of opening and ſhutting, yet the body of the fiſh is always ſecured, and is no more expoſed to ſight at one time than at another, and there is no part where the fiſh can be ſeen but at the ends.

This fiſh lives in the ſand on the ſea-ſhore, where it buries itſelf often a foot and a half, or two feet deep; the length of the ſhell is, at this time, nearly in a vertical poſition, and the fiſh has a power of raiſing itſelf at pleaſure up to the ſurface, and ſinking down again, while the ſhell remains all the time buried in its place. Almoſt all other animals have a horizontal motion, and the ſhell-fiſh of the ſea crawl along upon its bottom under water, as the common land animals do on dry ground; but this creature's progreſſive motion is only vertical, and that confined to a very ſmall compaſs; all that it is able to do for itſelf being only to raiſe itſelf higher or lower, and ſink deeper or riſe higher in the ſand, within the narrow compaſs of about two feet at the utmoſt, as the going beyond that muſt occaſion its deſtruction. Where theſe ſhell-fiſh are buried in the ſand, there is a hole reaching from every one of them to the ſurface, by means of which they have a free communication with the water: theſe holes generally are placed in great numbers near one another, and are eaſily diſtinguiſhed at a time when the tide has left the ſhore uncovered. They are not round, but oblong, and ſomewhat reſemble the key-hole of a lock, but that they have a roundneſs at each end, whereas that uſually is rounded only at one.

When it has occaſion to aſcend out of its hole, nothing more is required than the putting out the end of the leg, ſwelling it, and thus thruſting itſelf up to the length of that leg; then retracting it into the ſhell again, and thruſting out and inflating its end for a ſecond movement of the ſame kind. Theſe motions may be all perceived in the creature when out of the ſand, particularly that by which it buries itſelf; for if held up in the fingers, it thruſts out the leg, and performs all the motions as if in the ſand, making a fruitleſs attempt to ſave itſelf in its old way. Mem. Acad. Par. 1712. *ſ.*

Klein, and ſome others, have given the name ſolen to the ſeveral ſpecies of *tubuli marini*.

Solen, in *Geography*, a town of Weſtphalia; 6 miles S.S.W. of Magdeburg.

SOLENA, in *Botany*, ſo called by Willdenow, from σωλην, *a tube*, or *pipe*, in alluſion to the long tube of the flower. For the ſame reaſon, Schreber had named this ſame genus *Cyrtanthus*, but the latter appellation is now beſtowed on a very different one. (See Cyrtanthus.) Willd. Sp. Pl. v. 1. 961. (Cyrtanthus; Schreb. Gen. 122. Poſoqueria; Aubl. Guian. v. 1. 133. Juſſ. 201. Lamarck Illuſtr. t. 163.)—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, turbinate, in five acute, erect, permanent ſegments. *Cor.* of one petal; tube very long, cylindrical, recurved, dilated at the ſummit, its orifice fringed with hairs; limb in five deep, oblong, obtuſe, reflexed ſegments. *Stam.* Filaments five, capillary, very ſhort, incurved, ſomewhat unequal, inſerted into the mouth of the tube, between the ſegments of the limb; anthers oblong, acute at each end, attached by their baſe. *Piſt.* Germen inferior, elliptical; ſtyle capillary, as long as the tube; ſtigma minute, three-cleft. *Peric.* Berry elliptical, large, of one cell, full of pulp, and crowned with the calyx. *Seeds* about twelve, angular, imbedded in the pulp.

Eſſ. Ch. Calyx five-cleft, ſuperior, permanent. Corolla ſalver-ſhaped, with a very long, incurved tube, hairy at the mouth. Stamens inſerted into the rim of the tube. Style thread-ſhaped. Stigma three-cleft. Berry of one cell, with many angular ſeeds.

1. S. *longiflora*. Guiana Pipe-flower. Willd. n. 1.—(Poſoqueria longiflora; Aubl. Guian. v. 1. 134. t. 51.)—Found by Aublet, on the banks of the great rivers of Guiana, flowering in November, and bearing fruit in January. The Galibis call it *Aymara-poſoqueri*, becauſe a fiſh named *aymara* feeds on the berries. The *ſtem* is ſhrubby, five or ſix feet high, with a hard white wood, and ſlender,

knotty, ſmooth, oppoſite *branches*. *Leaves* oppoſite, ſtalked, elliptical, pointed, entire, veiny, ſmooth, about four inches long, each pair croſſing the next. *Stipulas* in pairs between the footſtalks, broad at the baſe, taper-pointed. *Flowers* about ſix, in a terminal *corymb*, white, drooping, ſlender, the tube of each about four inches long. *Fruit* yellow, ſucculent, ſweet, and pleaſant, the ſize of a guinea-hen's egg; the pulp red.

SOLENA is alſo the name of a genus, of the order of *Cucurbitaceæ*, in Loureiro's Fl. Cochinch. 514, which he thus denominates on account of the filaments forming a ſort of ſheath. The only ſpecies is *S. heterophylla*, a native of woods in China and Cochinchina, with which we are unacquainted, but which ſeems nearly related to *Bryonia;* only the *ſtamens* are monadelphous, and in the ſame flower with the *piſtil*. The *berries* are ſcarlet. *Root* tuberous, of many white, oblong, farinaceous knobs, eatable, and, according to the author we follow, uſeful in conſumptions and dyſenteries, as well as the ſeeds.

SOLENANDRIA, ſo called by Ventenat, in his Jardin de la Malmaiſon, from σωλην, *a tube*, becauſe of the union of the ſtamens. See GALAX.

SOLENHOFEN, in *Geography*, a town of Germany, in the principality of Anſpach; 29 miles S. of Anſpach.

SOLENIA, in *Botany*, a third generic name, (ſee SOLENA and SOLENANDRIA,) derived from σωλην, *a tube*, or *pipe*, is uſed in Hoffmann's *Flora Germanica*, v. 2. t. 8, for a minute genus of *Fungi*, whoſe tubular form it expreſſes. The ſpecies compoſing this ſuppoſed genus are, however, ſunk in *Peziza*, by Perſoon in his *Synopſis Fungorum*, 675, of which they conſtitute the ſeventh ſection, being in all four ſpecies. See PEZIZA.

SOLENOE, in *Geography*, a town of Ruſſia, in the government of Kolivan; 104 miles S. of Kolivan. N. lat. 52° 45′. E. long. 80° 54′.

SOLENOV, a lake of Ruſſia, 60 miles long and 20 broad, with two iſlands, between lake Aral and the Caſpian ſea. N. lat. 43° 50′ to 44° 50′. E. long. 56° 14′.

SOLES, in *Ancient Geography*, a town of Aſia, in Cilicia, on the ſea-coaſt, afterwards called Pompeiopolis.—Alſo, a town of the iſland of Cyprus, in which was a temple of Venus. See SOLOE.

SOLESMES, in *Geography*, a town of France, in the department of the North, and chief place of a canton, in the diſtrict of Cambray; 9 miles E.N.E. of Cambray. The town contains 3849, and the canton 16,419 inhabitants, on a territory of 140 kiliometres, in 17 communes.—Alſo, a town of France, in the department of the Sarte; 3 miles N. of Sable.

SOLE-TENANT, in *Law*, he or ſhe who holds lands only in his or her own right, without any other perſon joined.

E. gr. If a man and his wife hold lands for their lives, the remainder to their ſon: here, the man dying, the lord ſhall not have heriot, becauſe he dies not ſole-tenant.

SOLEURE, in *Geography*, a canton of Switzerland, holding the eleventh rank in the Helvetic confederacy, ſtretches partly through the plain, and partly along the chains of the Jura, and contains about 50,000 ſouls, including the inhabitants of the capital. The ſoil is, for the moſt part, fertile in corn; and thoſe diſtricts which lie within the Jura abound in excellent paſtures. The trade both of the town and canton is of little value, although the ſituation is commodious for an extenſive commerce. It is divided into eleven diſtricts or bailliages, called interior and exterior; the former are governed by bailifs, who are ſenators, and remain in the towns; the latter by bailifs ſelected from the members of the great council, who reſide in their bailliages. The inhabitants of the canton are Catholics, excepting thoſe in the bailliage of Buckegberg, who profeſs the reformed religion. In ſpiritual offices, the Catholics depend on three biſhops; but neither of theſe biſhops can iſſue any ordinance, or even viſit their dioceſes, without the approbation of the ſenate. In this canton are two chapters; alſo an abbey of Benedictines, four convents, and three nunneries. Its principal charitable inſtitutions are, an hoſpital at Soleure, and another at Olten, for the reception of burghers, ſubjects, and foreigners; the foundation of Thurigan, for old perſons of both ſexes belonging to the burgherſhip; a foundling hoſpital for orphans, and for children of poor burghers; and the hoſpital of St. Catharine, for the inſane and incurables. In eccleſiaſtical affairs, the inhabitants of Buckegberg, who profeſs the reformed religion, though ſubject to Soleure, are under the protection of Bern: and though formerly this complication of political and religious intereſts created frequent miſunderſtandings between the two cantons, yet matters were amicably and finally adjuſted on the 18th of November, 1618, at the treaty of Winingen. The inhabitants take the oath of fidelity, every third year, to the government of Soleure; but if aggrieved in their religious eſtabliſhment, can have recourſe to Bern. The ſenate of Bern nominates to the vacant benefices, but the prieſts are under the neceſſity of obtaining the confirmation of the chapter of Soleure. Bern alſo poſſeſſes ſupreme juriſdiction in criminal affairs. Soleure enjoys all the other rights of ſovereignty; ſuch as the power of levying taxes, appeals in the laſt reſort, and the deciſion of all matrimonial and eccleſiaſtical concerns, with this proviſo, that the deciſion ſhall be regulated according to the articles of the treaty of Winingen. With reſpect to the militia, all the males, from the age of 15 to 60, are formed into ſix regiments, conſiſting of about 8000 men, excluſive of 240 dragoons, and the corps of artillery, amounting to 600. The colonel of each regiment is always a ſenator, and the major a member, of the great council. The ſovereign power reſides in the great council, conſiſting of 102 members, choſen by the ſenate, in equal proportion, from the eleven tribes or companies into which the ancient burghers are diſtributed. The prerogatives of the great council are to enact and abrogate laws; to explain obſcure parts of the conſtitution, and make alterations in the form of government; to levy taxes, declare war, and conclude peace; to contract alliances, receive appeals in criminal caſes from the burghers of the capital, and in civil proceſſes above the ſum of two Swiſs livres, or 6*l.* 3*s.*; to confer the new burgherſhip, elect the treaſurer, or fourth chief of the republic, from the ancient eleven ſenators, nominate to the ſeven exterior bailliages, &c. &c. To be qualified for admiſſion into the great council, the candidate muſt be twenty years of age, an ancient burgher, and a member of the ſame tribe in which the vacancy happens. The great council aſſembles ordinarily once every month; and extraordinarily, when convened by the ſenate.

The ſenate, or little council, a conſtituent part of the great council, is compoſed of the two advoyers or chiefs of the public, who annually alternate; the chancellor, or ſecretary of ſtate, who has no vote; and 33 ſenators, drawn from the remaining 61 members of the great council, divided into 11 ſeniors and 22 juniors. The ſenate examines and digeſts all affairs, before they are ſubmitted to the great council; is entruſted with the executive power, and care of the police; receives all appeals in the firſt inſtance from the inferior courts of juſtice; gives judgment in all civil proceſſes, not exceeding the were uſed, during the chief part of the laſt century, by all ſinging-maſters unable to write to the wants and abilities of their ſcholars. But the paſſages in theſe, though excellent in their day, being now worn out and common, are generally ſuperſeded by the ſolfeggii of Aprile.

SOLFERINA, in *Geography*, a town of Italy, in the duchy of Mantua; 17 miles N.W. of Mantua.

SOLFWITZBURG, Solvesborg, or *Sylviſborg*, a ſeaport town of Sweden, in the province of Blekingen. This town, formerly more flouriſhing than it is at preſent, is almoſt ſurrounded by the Baltic ſea. It has a harbour, and a caſtle in a ruined ſtate. It is ſaid to be the place where the Lombards aſſembled when they left their country, and migrated in ſearch of new habitations; 35 miles W.S.W. of Carlſcrona. N. lat. 56° 9′. E. long. 14° 26′.

SOLI, or *Aſhaja Tuſla*, a town of Boſnia; 20 miles W.N.W. of Zwornick.

Soli, or *Jokari Tuſla*, a town of Boſnia; 16 miles W.N.W. of Zwornick.

SOLIANOI, a fortreſs of Ruſſia, in the government of Kolivan, on the Irtiſch. N. lat. 54° 20′. E. long. 75° 14′.—Alſo, a town of Ruſſia, in the government of Irkutſk; 20 miles N.N.W. of Selenginſk.

SOLIANSKOI Stanitz, a town of Ruſſia, in the government of Irkutſk, on the Lena; 16 miles N.E. of Olekminſk.

SOLICITATION *of Gravity*. See Paracentric.

SOLICITOR, or Sollicitor, *Solicitator*, a perſon employed to follow, and take care of, other perſons' ſuits depending in courts of law or equity; formerly allowed only to nobility, whoſe menial ſervants they were; but now regularly admitted to practiſe in the court of chancery. See Attorney.

The king has a ſolicitor-general, who holds his office by patent, during the king's pleaſure. The attorney-general and he had anciently a right to their writs of ſummons, to ſit in the lords houſe on ſpecial occaſions, till the 13 Car. II. ſince which time, they have almoſt conſtantly been choſen members of the houſe of commons.

The ſolicitor-general has the care and concern of managing the king's affairs, and hath fees for pleading, beſides other fees ariſing by patents, &c. He hath his attendance on the privy-council; and the attorney-general and he were anciently reckoned among the officers of the exchequer: they have audience, and come within the bar in all other courts.

To the queen's houſehold there belongs alſo an officer with this appellation. See Precedence.

SOLID, in *Phyſics*, a body whoſe minute parts are connected together, ſo as not to give way or ſlip from each other, upon the ſmalleſt impreſſion.

The word is uſed in this ſenſe, in contradiſtinction to *fluid*.

Solid *Bodies*, *Atmoſphere of*. See Atmosphere.

For the laws of gravitation of ſolids, immerged in fluids ſpecifically, either lighter or heavier than the ſolids, ſee Gravity and Fluid.

To find the ſpecific gravity of ſolids, and its ratio to that of fluids, ſee *Specific* Gravity.

For the laws of the reſiſtance of ſolids moving in fluids, ſee Resistance.

Solid, in *Geometry*, is a magnitude endued with three dimenſions, or extended in length, breadth, and depth. Hence, as all bodies have theſe three dimenſions, and nothing but bodies, ſolid and body are frequently uſed indiſcriminately.

A ſolid is terminated, or contained, under one or more planes or ſurfaces, as a ſurface is under one or more lines. From the circumſtances of the terminating lines, ſolids become divided into *regular* and *irregular*.

Solids, *Regular*, are thoſe terminated by regular and equal planes.

Under this claſs come the tetraëdron, hexaëdron or cube, octaëdron, dodecaëdron, and icoſaëdron. See Tetraedron, Cube, &c.; and for the meaſure of theſe bodies, ſee Mensuration.

Solids, *Irregular*, are all ſuch as do not come under the definition of regular ones. Such are the ſphere, cylinder, cone, parallelogram, priſm, pyramid, parallelepiped, &c.

For the ratio of geometrical ſolids, all priſms, parallelepipeds, cylinders, pyramids, and cones, are in a compound ratio of their baſes and altitudes; ſo that if the baſes be equal, they are in the ſimple ratio of the altitudes; or, if the altitudes be equal, they are as their baſes: and as the baſes of cylinders and cones are circles, and circles are in the duplicate ratio of their diameters, it follows that all cones and cylinders are in a ratio compounded of the direct ratio of their altitudes, and the duplicate ratio of their diameters.

The geneſes, properties, ratios, conſtructions, dimenſions, &c. of the ſeveral ſolids, regular and irregular, ſpherical, elliptical, conical, &c. ſee under each reſpective article. See alſo Mensuration.

Solid, *Meaſure of a*. See Measure.

Solid, *Cubature* or *Cubing of a*. See Cubature and Solidity.

Solids, *To find the Surfaces of*. See Area, Superficies, and Mensuration.

Solid *of the leaſt Reſiſtance*. See Resistance and Isoperimetry.

Solid *Angle*, is that formed by three or more plain angles meeting in a point. (See Angle.) Or, more ſtrictly, a ſolid angle, as B (*Plate* XIV. *Geometry*, *fig.* 1.), is the inclination of more than two lines, A B, B C, B F, which concur in the ſame point B, and are in the ſame planes.

Hence, for ſolid angles to be equal, it is neceſſary they be contained under an equal number of equal planes, diſpoſed in the ſame manner.

And as ſolid angles are only diſtinguiſhable by the planes under which they are contained, and as planes thus equal are only diſtinguiſhable by compreſence, they are ſimilar; and conſequently ſimilar ſolid angles are equal, and *vicé verſâ*.

The ſum of all the plane angles conſtituting a ſolid angle, is always leſs than 360°; otherwiſe they would conſtitute the plane of a circle, and not a ſolid.

The theory of ſolid angles is, perhaps, rather a ſubject of curioſity than utility; yet as it has given riſe to much diſcuſſion amongſt mathematicians, it may not be amiſs to beſtow a few lines in explanation of what we conſider to be the moſt ſcientific method of conſidering this ſubject.

Euclid defines a ſolid angle to be that which is made by the meeting of more than two plane angles, which are not in the ſame plane, in one point; but a more general definition is, that "a ſolid angle is the angular ſpace included between ſeveral plane ſurfaces, or one or more curve ſurfaces, meeting in the point which forms the ſummit of the angle."

According to this definition, ſolid angles bear juſt the ſame relation to the ſurfaces which compriſe them, as plane angles do to the lines by which they are included; ſo that, as in the latter, it is not the magnitude of the lines, but their mutual inclination, which determines the angle; juſt ſo, in the former, it is not the magnitude of the planes, but their mutual inclinations which determines the angles. And hence, all thoſe geometers, from the time of Euclid, who have confined their attention principally to the magnitude of the plane angles, inſtead of their relative poſitions, have never been able to develope the properties of this claſs of geometrical quantities; but have affirmed, that no ſolid angle can be ſaid to be half or double of another; and have ſpoken of the biſection, triſection, &c. of ſolid angles, even in the ſimpleſt caſes, as impoſſible problems. But all this ſuppoſed difficulty vaniſhes, and the doctrine of ſolid angles becomes ſimple and univerſal in its application, by aſſuming *ſpherical ſurfaces* for their meaſure, juſt as circular arcs are aſſumed for the meaſure of plane angles. This idea ſeems to have firſt occurred to Albert Girard, and publiſhed by him in his "Inventions Nouvelles en l'Algebra," an account of which is given at p. 7, vol. iii. Montucla's Hiſtory of Mathematics. The principle of this method, however, ſeems to have eſcaped the attention of geometers, till it was recently brought forward again in vol. iii. of Hutton's Courſe of Mathematics, the writer of which, it ſhould be obſerved, was not aware of the ſubject having been previouſly treated on the ſame principles by Girard. We ſhall, in what follows, avail ourſelves of the latter article.

Imagine, then, that from the ſummit of a ſolid angle, (formed by the meeting of three planes,) as a centre, any ſphere be deſcribed, and that thoſe planes are produced till they cut the ſurface of the ſphere; then will the ſurface of the ſpherical triangle, included between thoſe planes, be a proper meaſure of the ſolid angle, made by the planes at their common point of meeting, for no change can be conceived in the relative poſition of thoſe planes, without a correſponding and proportional mutation in the ſurface of the ſpherical triangle. If, in like manner, the three or more ſurfaces, which by their meeting conſtitute another ſolid angle, be produced till they cut the ſurface of the ſame, or an equal ſphere, whoſe centre coincides with the ſummit of the angle; the ſurface of the ſpheric triangle, or polygon, included between the planes which determine the angle, will be a correct meaſure of that angle. And the ratio which ſubſiſts between the areas of the ſpheric triangles, polygons, or other ſurfaces thus formed, will be accurately the ratio that ſubſiſts between the ſolid angles, conſtituted by the meeting of the ſeveral planes or ſurfaces at the centre of the ſphere.

Hence the compariſon of ſolid angles becomes a matter of great eaſe and ſimplicity; for, ſince the areas of ſpherical triangles are meaſured by the exceſs of the ſums of their angles, each above two right angles, and the areas of ſpherical polygons, of n ſides, by the exceſs of the ſum of their angles above $(2n - 4)$ right angles, it follows, that the magnitude of a trilateral ſolid angle will be meaſured by the exceſs of the ſum of the three angles, made reſpectively by its bounding planes above two right angles; and the magnitude of ſolid angles, formed by n bounding planes, by the exceſs of the ſum of the angles of inclination of the ſeveral planes above $(2n - 4)$ right angles.

As to ſolid angles, limited by curve ſurfaces, ſuch as the angles at the vertex of cones; they will manifeſtly be meaſured by the ſpheric ſurface, in the ſame manner as angles determined by plane ſurfaces, are meaſured by the triangles or polygons they mark out upon the ſame, or an equal ſphere. In all caſes, the maximum limit of ſolid angles will be the plane towards which various planes determining ſuch angles approach, as they diverge farther from each other about the ſame ſummit; the ſame as a right line is the maximum limit of plane angles, being formed by the two bounding-lines, when they make an angle of 180°. The maximum limit of ſolid angles is meaſured by the ſurface of the hemiſphere, in like manner as the maximum limit of plane angles is meaſured by the arc of a ſemicircle. The ſolid right angle (the angle, for example, of a cube) is $\frac{1}{4} = (\frac{1}{2})^2$ of the maximum ſolid angle; while the plane right angle is half the maximum plane angle.

The analogy between plane and ſolid angles being thus traced, we may proceed to exemplify this theory by a few inſtances; aſſuming 1000 as the numeral meaſure of the maximum ſolid angle = 4 times 90° ſolid = 360° ſolid.

1. The ſolid angles of right priſms are compared with great facility. For of the three angles made by the three planes, which by their meeting conſtitute every ſuch ſolid angle, two are right angles, and the third is the ſame as the correſponding plane angle of the polygonal baſe; on which, therefore, the meaſure of the ſolid angle depends. Thus, with reſpect to the right priſm with an equilateral triangular baſe, each ſolid angle is formed by planes, which reſpectively make angles of 90°, 90°, and 60°. Conſequently, $90° + 90° + 60° - 180° = 60°$, is the meaſure of ſuch angle, compared with 360°, the maximum angle, and is therefore one-ſixth of the maximum angle.

A right priſm, with a ſquare baſe, has, in like manner, each ſolid angle $= 90° + 90° + 90° - 180° = 90°$, which is one-fourth of the maximum angle; and thus it may be found that each ſolid angle of a right priſm, with an equilateral

triangular baſe = $\frac{1}{6}$ max. angle = $\frac{1}{6}$ .1000
ſquare baſe = $\frac{1}{4}$ - = $\frac{1}{4}$ .1000
pentagonal baſe = $\frac{3}{10}$ - = $\frac{3}{10}$ .1000
hexagonal = $\frac{1}{3}$ - = $\frac{1}{3}$ .1000
heptagonal = $\frac{5}{14}$ - = $\frac{5}{14}$ .1000
octagonal = $\frac{3}{8}$ - = $\frac{3}{8}$ .1000
nonagonal = $\frac{7}{18}$ - = $\frac{7}{18}$ .1000
decagonal = $\frac{2}{5}$ - = $\frac{2}{5}$ .1000
undecagonal = $\frac{9}{22}$ - = $\frac{9}{22}$ .1000
duodecagonal = $\frac{5}{12}$ - = $\frac{5}{12}$ .1000
m-gonal - = $\frac{m-2}{2m}$ - = $\frac{m-2}{2m}$ .1000

Hence it may be ſhewn, that each ſolid angle of a regular priſm with triangular baſe, is *half* each ſolid angle of a priſm of an hexagonal baſe. Each with regular

ſquare baſe = $\frac{2}{3}$ of each with regular octagonal baſe.
pentagonal = $\frac{3}{4}$ - - - decagonal.
hexagonal = $\frac{4}{5}$ - - - duodecagonal.
$\frac{1}{2}$ m-gonal = $\frac{m-4}{m-2}$ - - - m-gonal.

Hence, again, we may infer, that the ſum of all the ſolid angles of any priſm of triangular baſe, whether that baſe be regular or irregular, is half the ſum of the ſolid angles of a priſm of quadrangular baſe, regular or irregular; and the ſum of the ſolid angles of any priſm of

tetragonal baſe = $\frac{2}{3}$ ſum of angles of pentagonal baſe.
pentagonal baſe = $\frac{3}{4}$ - - - hexagonal.
hexagonal baſe = $\frac{4}{5}$ - - - heptagonal.
m-gonal baſe = $\frac{m-2}{m-1}$ - - - $(m+1)$-gonal.

2. Let us now compare the ſolid angles of the five regular bodies. In theſe bodies, if m be the number of ſides of each face; n the number of planes which meet at each

ſolid angle; $\pi = \frac{1}{2}$ circumference, or 180°; and A the plane angle made by two adjacent faces; then we have

$$\text{ſin.}\ \tfrac{1}{2}A = \frac{\text{coſ.}\ \dfrac{\pi}{n}}{\text{ſin.}\ \dfrac{\pi}{n}}.$$

This theorem gives for the plane angle formed by every two contiguous faces of the tetraëdron, 70° 31′ 42″; of the hexaëdron, 90°; of the octaëdron, 109° 28′ 18″; of the dodecaëdron, 116° 33′ 54″; of the icoſaëdron, 138° 11′ 23″. But in theſe polyedræ, the number of faces meeting about each ſolid angle are 3, 3, 4, 3, 5, reſpectively. Conſequently the ſolid angles will be determined by the ſubjoined proportions.

$$360^\circ : 1000 :: \begin{cases} 3\,(70^\circ 31' 42'') - 180^\circ : \ 87.736 & \text{tetraë.} \\ 3\,(90^\circ) \qquad\quad\ \ - 180^\circ : 250 & \text{hexaë.} \\ 4\,(109^\circ 28' 18'') - 180^\circ : 216.351 & \text{octaë.} \\ 3\,(116^\circ 33' 54'') - 180^\circ : 471.395 & \text{dodecaë.} \\ 5\,(138^\circ 11' 23'') - 180^\circ : 419.301 & \text{icoſaë.} \end{cases}$$

3. Solid angles at the vertices of cones, will be determined by means of the ſpheric ſegments cut off at the baſes of thoſe cones; that is, if right cones, inſtead of having plane baſes, had baſes formed of the ſegments of equal ſpheres, whoſe centres were the vertices of cones, the ſurface of thoſe ſegments would be the meaſures of the ſolid angles at the reſpective vertices. Now the ſurface of ſpheric ſegments, is to the ſurface of the hemiſphere, as the altitudes to the radius of the ſphere; and, therefore, the ſolid angle at the vertices of right cones, will be to the maximum ſolid angle, as the exceſs of the ſlant ſide above the axis of the cone, to the ſlant ſide of the cone. Thus, if we wiſh to aſcertain the ſolid angles at the vertices of the equilateral and right-angled cones; the axis of the former is $\frac{1}{2}\sqrt{3}$, and of the latter $\frac{1}{2}\sqrt{2}$, the ſlant ſide of each being unity. Hence,

$1 : 1 - \frac{1}{2}\sqrt{3} :: 1000 : 133.97$ angle at vertex equilateral cone.

$1 : 1 - \frac{1}{2}\sqrt{2} :: 1000 : 292.98$ - - right-angled.

4. From what has been ſaid, the mode of determining the ſolid angles at the vertices of pyramids will be ſufficiently obvious. If the pyramids be regular ones, and N repreſent the number of faces meeting about the vertical angle in one, and A the angle of inclination of each two of its plane faces; alſo n the number of planes meeting about the vertex of another, and a the angle of inclination of each two of its faces; then will the vertical angle of the former, be to the vertical angle of the latter, as

$$NA - (N-2)\,180^\circ, \text{ to } na - (n-2)\,180^\circ.$$

If a cube be cut by diagonal planes into ſix equal pyramids, with ſquare baſes, their vertices all meeting in the centre of the circumſcribing ſphere; then each of the ſolid angles made by the four planes meeting at each vertex, will be $\frac{1}{3}$d of the maximum ſolid angle; and each of the ſolid angles at the baſes of the pyramids will be $\frac{1}{12}$th of the maximum ſolid angle. Therefore, each ſolid angle at the baſe of ſuch pyramid is $\frac{1}{4}$th of the ſolid angle at its vertex, and if the angle at the vertex be biſected, either of the ſolid angles ariſing from the biſection will be double of either ſolid angle at the baſe; hence alſo each ſolid angle of a priſm with equilateral triangular baſe, will be half each vertical angle of theſe pyramids, and double each ſolid angle at their baſe.

Solid *Figures, Like.* See Like.

Solid *Baſtion.* See Bastion.

Solid *Place.* See Locus.

Solid *Foot.* See Foot.

Solid *Numbers*, are thoſe which ariſe from the multiplication of a plain number, by any other whatſoever.

Thus, 18 is a ſolid number made of 6 (which is plain) multiplied by 3; or of 9 multiplied by 2.

Solid *Problem*, in *Mathematics*, is one which cannot be geometrically ſolved, but by the interſection of a circle and a conic ſection; or by the interſection of two other conic ſections beſides the circle.

Thus, to deſcribe an iſoſceles triangle on a given right line, whoſe angle at the baſe ſhall be triple to that at the vertex, is a ſolid problem, reſolved by the interſection of a parabola and a circle.

Solid *Root*, among *Botaniſts*, expreſſes the whole root to be one uniform lump of matter.

Solid *Square*, in *Military Language*, a body of foot where both ranks and files are equal.

Solid *Theorem.* See Theorem.

Solid *Celery*, in *Gardening*, that ſort which is of a firm criſp nature, without any kind of opening or hollowneſs in the middle part of the ſtems. There is a ſort of this kind, which has a very ſlight reddiſh tinge, that is greatly eſteemed in ſome places. Solid celery commonly eats in a more criſp and agreeable manner than the hollow ſort, and on that account is, for the moſt part, cultivated in the gardens of thoſe who do not raiſe the plant for ſale; but in the market-gardens, where ſale is the great object, the common hollow kind is the ſort that is the moſt in cultivation, as it grows much more quickly, and of courſe becomes ſooner ready to be diſpoſed of in the market, nor does the ſolid ſort ſtand the froſt ſo well in the winter. Celery being ready at an early period is a matter of very great importance and conſideration in theſe ſituations, in conſequence of the difference in price being often ſo great, as that which is early will not unfrequently fetch double the price, and more, of that which is late. See Apium.

Neither this ſolid ſort, nor the tall or giant celery, as it is called, are commonly thought ſo fit for winter crops. This ſolid kind was not known until long after the hollow ſort had been in uſe, and the above variety is but lately known and cultivated.

SOLIDAGO, in *Botany*, from *ſolido*, to make firm, and, particularly, to heal a wound; an old name, ſynonimous with the Engliſh word Conſound, and intended to expreſs the reputed vulnerary powers of the plants which bore it.—Linn. Gen. 425. Schreb. 556. Willd. Sp. Pl. v. 3. 2053. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 64. Sm. Fl. Brit. 889. Prodr. Fl. Græc. Sibth. v. 2. 179. Purſh 535. Juſſ. 181. Lamarck Illuſtr. t. 680. Gærtn. t. 170. (Virga aurea; Tourn. t. 275.) Claſs and order, *Syngeneſia Polygamia-ſuperflua.* Nat. Ord. *Compoſitæ diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common Calyx* oblong, imbricated, with oblong, narrow, pointed, ſtraight, converging ſcales. *Cor.* compound, radiated. Florets of the diſk numerous, perfect, tubular, funnel-ſhaped, with a five-cleft ſpreading limb; thoſe of the radius fewer than ten, uſually five, ligulate, lanceolate, three-toothed, female. *Stam.* in the perfect florets, Filaments five, capillary, very ſhort; anthers united into a cylindrical tube. *Piſt.* in the ſame florets, Germen oblong; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma cloven, ſpreading: in the female ones, Germen and ſtyle as in the former; ſtigmas two, revolute. *Peric.* none, the calyx remaining ſcarcely changed. *Seeds* ſolitary to each floret of the diſk, obovate-oblong. Down capillary. Thoſe of the radius much the ſame. *Recept.* flattiſh, dotted, naked.

Eſſ. Ch. Receptacle dotted, naked. Down ſimple. Calyx imbricated, with converging ſcales. Florets of the radius about five.

The ſpecies of this genus, almoſt entirely American, vie with thoſe of *Aſter* in difficulty of determination. They are all perennial, moſtly herbaceous, with ſimple undivided leaves, and panicled or ſpiked, almoſt always yellow, ſmall flowers, and are known by the name of Golden Rods. Several are cultivated for ornament, more for curioſity. The *Hortus Kewenſis*, enriched from Dr. Solander's manuſcripts, has thrown great light on the preſent genus, as well as on *Aſter*. Linnæus in Syſt. Veg. ed. 14, has only fourteen ſpecies of *Solidago;* Willdenow, profiting by Mr. Aiton's work, enumerates forty. Mr. Purſh reckons up fifty-one North American ſpecies alone. One only, ſubject to many varieties, is found in Britain.

So great a number of ſpecies now require to be added to Willdenow's catalogue, that it is neceſſary to take a compendious view of the whole, eſpecially as we are furniſhed with more authentic ſpecimens than moſt writers have had at their command.

Section 1. *Arboreſcent.*

1. S. *ſpuria.* Baſtard Tree Golden-rod. "Forſt. Comm. Gott. v. 9. 68." Willd. n. 1. (Conyza rugoſa; Ait. Hort. Kew. v. 5. 30.) — Stem arboreous. Panicle corymboſe. Leaves oblong, wedge-ſhaped, ſerrated.—Native of St. Helena. Brought by ſir Joſeph Banks, in 1772, to Kew garden, where it flowers in the greenhouſe in November. A ſpreading irregular ſmall *tree*, with thick rugged *branches*, leafy at the ends. *Leaves* ſtalked, rugoſe, bright green, from a ſpan to a foot long. *Panicles* large, level-topped. *Flowers* white, half an inch in diameter, with ten florets in the radius. *Forſter.*

2. S. *Leucadendron.* White Tree Golden-rod. "Forſt. ibid. 69." Willd. n. 2. — "Stem arboreſcent. Cymes level-topped. Leaves oblong-obovate, crenate, nearly ſeſſile."—Native of woods in St. Helena. A *tree*, two or three fathoms in height. *Branches* dark brown, tuberculated, rather level-topped; leafy at the ſummit. *Leaves* ſmooth, ſpreading, three inches long, tapering at the baſe.—*Flower-ſtalks* cymoſe, ſmooth and ſlender. *Flowers* in every part like the preceding. *Forſter.*

3. S. *arboreſcens.* New Zeeland Tree Golden-rod. Forſt. Prodr. 56. Willd. n. 3.—"Stem arboreous. Panicles corymboſe, cloſe, terminal. Leaves roundiſh-ovate, acute, wavy, ſtalked."—Native of New Zeeland. Young *branches* downy. *Leaves* bluntly and diſtantly toothed; downy beneath. *Willd.*

Section 2. *Herbaceous. Flowers unilateral. Leaves with three combined ribs.*

4. S. *canadenſis.* Canadian Golden-rod. Linn. Sp. Pl. 1233. Willd. n. 4. Ait. n. 1. Purſh n. 1. (Virga aurea anguſtifolia, paniculâ ſpecioſâ, canadenſis; Pluk. Almag. 389. t. 236. f. 1.)—Stem downy. Leaves lanceolate, ſerrated, triple-ribbed, rough. Cluſters copious, panicled, unilateral, recurved. Radius hardly exceeding the diſk.—In hedges, old fields, and along fences, from Canada to Pennſylvania, flowering from July to September. From eighteen inches to five feet high. *Purſh.* The *ſtem* is angular, terminated by an ample downy *panicle*, of innumerable very ſmall yellow *flowers*. *Leaves* ſeſſile, three inches long, ſometimes nearly entire, and occaſionally downy. Purſh and, of courſe, Willdenow, copy the erroneous reference to Plukenet; a practice which overturns all confidence in the ſynonyms of authors who uſe it, as they cannot have judged of the deſcription or figure cited.

5. S. *procera.* Great Golden-rod. Ait. n. 2. Willd. n. 5. Purſh n. 2. — "Stem villous, erect. Leaves lanceolate, ſerrated, triple-ribbed, rough; villous beneath. Cluſters ſpiked, erect, drooping before flowering. Radius ſhort."—In ſwamps, hedges, and about fences, from Canada to Virginia, flowering from July to September. From four to ſeven feet high. *Purſh.*

6. S. *ſerotina.* Upright Smooth Golden-rod. Ait. n. 3. Willd. n. 6. Purſh n. 3.—Stem erect, round, very ſmooth. Leaves linear-lanceolate, ſmooth, triple-ribbed, ſerrated, rough-edged. Cluſters panicled, unilateral. Stalks downy.—In woods and hedges, from New England to Pennſylvania, flowering in September and October. Young *leaves* edged with copious little white rigid hairs.

7. S. *gigantea.* Gigantic Golden-rod. Ait. n. 4. Willd. n. 7. Purſh n. 4.—Stem erect, ſmooth. Leaves lanceolate, ſmooth, ſerrated, rough-edged, obſcurely triple-ribbed. Cluſters paniculated, unilateral. Stalks hairy. Radius ſhort.—In open low places, on the ſides of fertile hills, from New England to Virginia, flowering from Auguſt to October. From four to ſeven feet high. *Purſh.*

8. S. *ciliaris.* Fringed Golden-rod. Willd. n. 8. Purſh n. 5.—Stem erect, ſmooth. Leaves lanceolate, ſomewhat triple-ribbed, ſmooth, rough-edged, ſlightly ſerrated. Cluſters panicled, unilateral. Stalks ſmooth. Bracteas fringed. Radius ſhort.—Sent from Pennſylvania, by the late Rev. Dr. Muhlenberg. The *ſtem* is angular. Radical *leaves* ſtalked, elliptical, pointed, veiny, ſerrated, rough, near a foot long. Branches of the *panicle* ſpreading. *Bracteas* minute. *Willd.*

9. S. *reflexa.* Hanging-leaved Golden-rod. Ait. n. 5. Willd. n. 9. Purſh n. 6. — Stem erect, villous. Leaves lanceolate, ſomewhat ſerrated, triple-ribbed, rough, reflexed. Cluſters panicled, ſlightly unilateral. — In pine woods and old fields, from New Jerſey to Carolina, flowering in Auguſt and September.

10. S. *lateriflora.* Lateral-flowered Golden-rod. Ait. n. 6. Willd. n. 10. Purſh n. 7. Linn. Sp. Pl. 1234? —Stem erect, rather hairy. Leaves lanceolate, obſcurely triple-ribbed, ſmooth, rough-edged; the lower ones ſlightly ſerrated. Cluſters panicled, unilateral, ſomewhat recurved. —In old fields and dry woods, from Canada to Carolina, flowering from Auguſt to October. The *ſtem* is from two to three feet high, ſtriated, often purpliſh, furniſhed with numerous lateral flowering branches, as well as a principal terminal one. *Leaves* very ſmooth in the diſk. *Radius* much longer than the calyx. This is probably the Linnæan plant, but ſome obſcurity attends that queſtion.

Section 3. *Cluſters unilateral. Leaves veiny.*

11. S. *aſpera.* Rough-leaved Golden-rod. Ait. n. 7. Willd. n. 11. Purſh n. 8. (Virga aurea americana aſpera, foliis brevibus ſerratis; Dill. Elth. 411. t. 305.)—Stem erect, round, hairy. Leaves ovate, rather elliptical, very rough, rugged, ſerrated, without lateral ribs. Cluſters panicled, unilateral.—In barren dry fields and woods, from New York to Carolina, flowering from September to November. *Purſh.* About a yard high. *Leaves* from one to two inches long, acute. *Cluſters* denſe, in ſome degree conical. *Flowers* ſmall, yellow, the radius twice as long as the calyx.

12. S. *altiſſima.* Tall Variable Golden-rod. Linn. Sp. Pl. 1233. Willd. n. 12. Ait. n. 8. Purſh n. 9. (Virga aurea altiſſima ſerotina, paniculâ ſpecioſâ patulâ; Mart. Cent. 14. t. 14; and probably V. aurea marilandica, ſpicis florum racemoſis, foliis integris ſcabris; ibid. 13. t. 13.)—Stem erect, hairy. Leaves lanceolate; the lower ones deeply ſerrated, very rough, rugoſe. Panicles unilateral.—

In hedges and fields of North America, common, flowering from Auguſt to October. A very variable ſpecies, ſcarcely two individuals look alike. *Purſh.* The numerous panicled *cluſters* ſpread horizontally, in a graceful manner, and all the *flowers* are turned upward. They are twice the ſize of *S. canadenſis*, with a prominent *radius*, half as long again as the *calyx*.

13. S. *rugoſa.* Wrinkle-leaved Golden-rod. Mill. Dict. ed. 8. n. 25. Willd. n. 13. Ait. n. 9. Purſh n. 10. (Virga aurea novæ angliæ, rugoſis foliis crenatis; Dill. Elth. 416. t. 308.) — Stem erect, hairy. Leaves ovato-lanceolate; the lower ones cloſely ſerrated, rugged, very rough. Cluſters panicled, compound, widely ſpreading, unilateral.—In a dry barren ſoil, from Canada to Virginia, flowering from Auguſt to October. *Purſh.* The *leaves* are ſhorter and broader than in the foregoing. *Flowers* rather ſmaller.

14. S. *villoſa.* Soft-leaved Golden-rod. Purſh n. 11. (S. altiſſima β; Ait. ed. 1. v. 3. 212. ed. 2. n. 8. Willd. n. 12. S. piloſa; Mill. Dict. ed. 8. n. 9.)—“ Stem erect, villous. Leaves lanceolate, rather ſoft, ſerrated, without lateral ribs. Cluſters panicled, unilateral.”—In fields and woods of North America frequent, flowering from Auguſt to October. From eighteen inches to three feet high. *Purſh.*

15. S. *ſcabra.* Harſh-leaved Golden-rod. Willd. n. 14. Purſh n. 12. — “ Stem erect, hairy. Leaves oblong, pointed; ſmooth above; rugged and rough beneath. Cluſters unilateral.”—In old fields and about fences, from Pennſylvania to Virginia, flowering from Auguſt to October. *Purſh.* *Stem* furrowed. *Leaves* tapering at each end, pointed, with equal, ſhort, cloſe-preſſed ſerratures about the middle.

16. S. *pyramidata.* Pyramidal Golden-rod. Purſh n. 13.—“ Stem erect, round, hairy. Leaves oblong, acute, ſeſſile, ſomewhat claſping the ſtem, ſmooth, rough-edged, ſparingly and ſlightly toothed. Panicle naked, unilateral, pyramidal; its branches reflexed. Flower-ſtalks ſmooth.”—Gathered by Mr. Enſlen, in the “ pine-barrens” of Georgia, flowering in Auguſt and September. About two feet high. The *leaves* decreaſe toward the beginning of the *panicle*, which conſiſts of lively yellow very ſmall *flowers*. *Purſh.*

17. S. *nemoralis.* Woolly-ſtalked Golden-rod. Ait. ed. 1. v. 3. 213. ed. 2. n. 10. Willd. n. 15. Purſh n. 14. — “ Stem erect, downy. Stem-leaves lanceolate, hiſpid, entire; radical ones ſomewhat wedge-ſhaped, ſerrated. Cluſters panicled, unilateral.”—In ſandy and barren fields common, from Canada to Carolina, flowering from Auguſt to October. The whole *plant* has a grey aſpect, and is about a foot, or ſometimes two, high. *Purſh.*

18. S. *patula.* Short-ſpreading-branched Golden-rod. Willd. n. 16. Purſh n. 15.—Stem erect, ſmooth, angular. Leaves elliptical, ſerrated, ſmooth; the radical ones oblong-ſpatulate. Cluſters panicled, unilateral, ſpreading. Flower-ſtalks downy.—In ſhady woods, on a fertile ſoil, from New York to Virginia, flowering in September and October. Our ſpecimen was ſent by the diſcoverer of this ſpecies, the Rev. Dr. Muhlenberg, from Lancaſter, Pennſylvania. Its *ſtems* are upright and wand-like, two feet high, angular and ſtriated. *Stem-leaves* ſeſſile, an inch long, pointed; the radical ones are ſaid by Willdenow to reſemble exactly thoſe of *Chryſanthemum Leucanthemum.* The *flowers* are larger than moſt of the foregoing, but each *cluſter* is hardly above an inch in length.

19. S. *ulmifolia.* Elm-leaved Golden-rod. Willd. n. 17. Purſh n. 16.—“ Stem erect, ſtriated, ſmooth. Leaves elliptical, pointed, deeply ſerrated; villous beneath: radical ones obovate. Cluſters panicled, unilateral. Flower-ſtalks villous. Rays ſhort.”—In ſwamps and ſhady woods, from New York to Virginia, flowering from Auguſt to October. *Purſh.* Radical *leaves* almoſt the ſame as the laſt, but more deeply ſerrated, covered with hairs on both ſides; the reſt elliptical or ovate-oblong; ſmooth above; villous about the veins beneath. *Flower-ſtalks* villous; the partial ones clothed with ſcattered hairs, and accompanied by *bracteas.*

20. S. *arguta.* Sharp-notched Golden-rod. Ait. ed. 1. v. 3. 213. ed. 2. n. 11. Willd. n. 18. Purſh n. 17.—“ Stem erect, ſmooth. Leaves ſmooth, ſharply and unequally ſerrated; thoſe of the ſtem elliptical; radical ones ovate-oblong. Cluſters panicled, unilateral. Rays elongated.”—In woods and meadows, from Canada to Virginia, flowering from September to November. *Purſh.*

21. S. *juncea.* Ruſhy-ſtalked Golden-rod. Ait. ed. 1. v. 3. 213. ed. 2. n. 12. Willd. n. 19. Purſh n. 18.—Stem erect, ſmooth. Leaves lanceolate, ſmooth, rough-edged; the lower ones ſerrated. Cluſters panicled, unilateral.—In ſandy fields and woods, from New Jerſey to Carolina, flowering from Auguſt to October. The *ſtem* is browniſh, ſomewhat angular and ſtriated, leafy, copiouſly panicled at the top, with ſpreading, recurved, denſe, oblong, compound *cluſters*, a finger's length or more, whoſe partial ſtalks are roughiſh, bearing many ſmall, lanceolate, obtuſe *bracteas.* *Florets* of the radius twice as long as the calyx.

22. S. *elliptica.* Oval-leaved Golden-rod. Ait. ed. 1. v. 3. 214. ed. 2. n. 13. Willd. n. 20. Purſh n. 19. (S. latiſſimifolia; Mill. Dict. ed. 8. n. 14. Virga aurea canadenſis, latiſſimo folio glabro; Tourn. Inſt. 485.)—Stem erect, ſmooth. Leaves elliptical, ſmooth, ſerrated. Cluſters panicled, unilateral. Rays of a middling length.—In ſhady woods among rocks, from New York to Virginia, flowering from Auguſt to October. *Purſh.*

23. S. *dubia.* Lanceolate-leaved Golden-rod. Scopoli Del. Inſubr. v. 2. 19. t. 10.—Stem erect, ſtriated, ſlightly hairy. Leaves lanceolate, ſmooth, diſtantly toothed. Cluſters panicled, unilateral, rather hairy; the lower ones axillary. Bracteas lanceolate, ſmooth.—Cultivated in the botanic garden of Pavia, from whence we obtained a ſpecimen in June, 1787. The plant was ſuppoſed by profeſſor Scopoli to be a native of North America, but we cannot refer it to any deſcribed ſpecies. The late Mr. Dryander, at that time intent on preparing the *Hortus Kewenſis* for the preſs, conſidered our ſpecimen as coming neareſt to *S. elliptica*, but its *leaves* are narrower, and *bracteas* much leſs. Moſt of the *cluſters* are axillary, compoſing a leafy *panicle*, and about as long as their correſponding leaves. *Florets* of the radius rather numerous. The *foliage* is rigid, entirely ſmooth, finely toothed, not ſerrated, ſomewhat triple-ribbed; indeed more ſo than in *lateriflora*, n. 10, next to which ſpecies, in the firſt ſection, we ſhould have placed the preſent, but for its alleged affinity to *elliptica.*

24. S. *aſperata.* File-leaved Golden-rod. “ Bankſ. MSS.” Purſh n. 20. — “ Stem panicled, corymboſe. Cluſters nearly erect. Flowers aſcending. Leaves lanceolate, ſerrated, rough.” — In Canada, according to the Bankſian herbarium. *Purſh.*

25. S. *recurvata.* Recurved Golden-rod. Willd. Enum. 889. Purſh n. 21.—Stem erect, downy. Leaves lanceolate, ſerrated, rough-edged. Cluſters elongated, unilateral, recurved, panicled. In ſhady woods, from Pennſylvania to Virginia, flowering from September to November. *Purſh.* *Leaves* lanceolate, pointed, deeply ſerrated, nearly ſmooth, except at the edges. *Willdenow.*

26. S. *ſempervirens.* Narrow-leaved Evergreen Golden-rod. Linn. Sp. Pl. 1232. Willd. n. 21. Ait. n. 14.

Purſh n. 22. (S. maxima americana; Cornut. Canad. 168. t. 169. Virga aurea, ſive Solidago procerior americana, caule multiplici; Pluk. Phyt. t. 235. f. 5.)—Stem erect, ſmooth. Leaves linear-lanceolate, rather fleſhy, ſmooth, entire, rough-edged. Cluſters panicled, unilateral. Flower-ſtalks roughiſh.—In ſwamps, and on the banks of rivers, from Canada to Pennſylvania, flowering from September to November. *Purſh.* A tall, ſmooth, purpliſh and ſomewhat glaucous ſpecies, with copious, long, narrow *leaves*, and denſe oblong *panicles*, of unilateral cluſters. Radiant *florets* long, narrow, rather numerous.

27. S. *virgata.* Slender Wand-like Golden-rod. Michaux Boreal-Amer. v. 2. 117. Purſh n. 23.—“Stem ſmooth, quite ſimple. Leaves lanceolate, ſomewhat wedge-ſhaped, obtuſe, entire, very ſmooth, cloſe-preſſed; the upper ones gradually ſmaller. Branches of the panicle elongated, with terminal cluſters. Flower-ſtalks ſmooth, unilateral.”—In ſhady wet woods of Lower Carolina and Georgia, flowering from Auguſt to October. About two feet high, extremely ſmooth and ſlender. *Purſh.*

28. S. *odora.* Sweet-ſcented Golden-rod. Ait. ed. 1. v. 3. 214. ed. 2. n. 15. Willd. n. 22. Purſh n. 24. (Virga aurea americana, tarraconis facie et ſapore, paniculâ ſpecioſiſſimâ; Pluk. Phyt. t. 116. f. 6.)—Stem erect, downy, ſtriated. Leaves linear-lanceolate, entire, ſmooth, rough-edged. Cluſters panicled, unilateral, nearly ſimple.—In dry ſunny ſituations, on fertile woodlands, from Canada to Carolina, principally throughout the Allegany mountains, flowering from Auguſt to October. This is moſt generally and principally known among the inhabitants by the name of Golden-rod, and uſed as a wholeſome tea. The flowers, gathered when fully expanded, and carefully dried, afford a moſt agreeable ſubſtitute for tea, which for ſome time has been an article of exportation to China, where it fetches a high price. *Purſh.* The upper part of the *ſtem* is regularly furrowed. *Cluſters* two or three inches long, ſpreading horizontally, each moſtly accompanied by a leaf; their *ſtalks* angular and rough. *Bracteas* oblong, ſmooth.

29. S. *retrorſa.* Reflexed Golden-rod. Michaux Boreal-Amer. v. 2. 117. Purſh n. 25.—“Stem erect, round, rough. Leaves cloſely ſeſſile, reflexed, linear-lanceolate, pointed, rough-edged; ſomewhat keeled beneath. Cluſters of the panicle recurved.”—In open ſwamps of Virginia and Carolina, flowering in Auguſt and September. *Purſh.* Said by Michaux to be akin to the laſt. We have had no opportunity of comparing them.

Section 3. *Cluſters erect.*

30. S. *paucifloſculoſa.* Starved-flowered Golden-rod. Michaux Boreal-Amer. v. 2. 116. Purſh n. 26.—“Smooth, ſomewhat ſhrubby. Leaves lanceolate, obtuſe, without ribs. Panicle compound, many-flowered; tufts of flowers erect. Calyx narrow-oblong, with five florets in the diſk, and one in the radius.”—In the “ſand-barrens” of Virginia and Carolina, flowering from Auguſt to October. *Purſh.*

31. S. *bicolor.* Two-coloured Golden-rod. Linn. Mant. 114. Willd. n. 23. Ait. n. 16. Purſh n. 27. (Virga aurea, flore albo ſpicato; Pluk. Phyt. t. 114. f. 8, not 3, as Willdenow and Purſh have it.)—Stem hairy. Leaves elliptical, hairy; the lower ones ſerrated; thoſe on the flower-branches entire, numerous, and ſmall. Cluſters erect. Scales of the calyx obtuſe.—In woods and on dry hills, from Canada to Carolina, flowering from Auguſt to October. Diſtinguiſhed by its ſhort cloſe *cluſters*, and white *rays*, which are not long, but rather numerous. The *florets* of the diſk are alſo plentiful.

32. S. *petiolaris.* Late-flowered Golden-rod. Ait. ed. 1. v. 3. 216. ed. 2. n. 17. Willd. n. 24. Purſh n. 28.—Stem erect, villous. Leaves elliptical, roughiſh, ſtalked. Cluſters erect. Rays twice the length of the calyx.—In dry ſandy ſoil, from New Jerſey to Carolina, flowering from September to November.—The *ſtem* is branched, round, hoary like the *leaves*, eſpecially their ribs. The larger *leaves* are rather above an inch in length; thoſe which plentifully clothe the flower-branches are much ſmaller; all are nearly entire. *Cluſters* numerous, erect, ſhort, of few, but rather large, *flowers*, with a conſpicuous yellow *radius*.

33. S. *ſtricta.* Willow-leaved Golden-rod. Ait. ed. 1. v. 3. 216. ed. 2. n. 18. Willd. n. 25. Purſh n. 29.—“Stem erect, ſmooth. Stem-leaves lanceolate, entire, ſmooth, rough-edged; radical ones ſerrated. Cluſters panicled, erect. Flower-ſtalks ſmooth.”—In ſandy woods, from New Jerſey to Carolina, flowering from Auguſt to November.—About two feet high, very ſmooth. *Purſh.* *Panicle* with erect, ſimple, cloſe branches. *Willd.*

34. S. *lanceolata.* Graſs-leaved Golden-rod. Linn. Mant. 114. Willd. n. 26. Ait. n. 19. Purſh n. 30. (Chryſocoma graminifolia; Linn. Sp. Pl. 1178.)—Stem ſmoothiſh, furrowed, much branched. Leaves almoſt linear, entire, roughiſh, nearly erect, with three or five rough ribs. Corymbs terminal, level-topped. Flowers capitate. Rays not longer than the diſk.—In fields and meadows, by the ſides of woods and rivers, from Canada to Pennſylvania, flowering from September to November. This plant has been found in Scotland, on the banks of the Eſk, a mile above Muſſelburgh, among willows, alders, &c. by Mr. E. J. Maughan of Edinburgh, in September 1809. Still we have not ventured to admit into the Britiſh liſt, a plant often met with in gardens, and very rapid in propagation, though many have been admitted on far leſs ſufficient grounds. The *ſtems* are four or five feet high, branched in a corymboſe manner, leafy, angular or furrowed, ſlightly rough, or quite ſmooth. *Leaves* ſeſſile, graſs-green, two inches or more in length, a quarter of an inch in breadth, roughiſh, eſpecially at the edges and ribs. *Flowers* numerous, rather ſmall, denſely corymboſe, yellow. *Calyx* ovate, ſmooth, ſhining, with tumid green-tipped ſcales.

35. S. *tenuifolia.* Narrow-leaved Golden-rod. Purſh n. 31. (S. lanceolata β, minor; Michaux Boreal-Amer. v. 2. 116.)—“Stem rough, angular, branched, corymboſe. Leaves ſpreading, linear, very narrow, ſlightly three-ribbed, rough, with axillary tufts of ſmaller ones. Corymbs terminal, level-topped. Flowers capitate. Rays ſcarcely exceeding the diſk.”—In “pine-barrens,” from New Jerſey to Carolina, flowering in September and October. Not above a foot high. *Leaves* very ſmall and narrow. *Purſh.*

36. S. *Sarothræ.* Cloſe-leaved Dwarf Golden-rod. Purſh n. 32.—“Stem angular, rough; naked in the lower part; corymboſe above. Branches with a few terminal flowers. Leaves linear, cloſe-preſſed, obſcurely three-ribbed, rough on both ſides, without axillary tufts. Rays twice the length of the diſk.”—Gathered by governor Lewis, on the plains of the Miſſouri, flowering in September.—About a ſpan high, reſembling the *Sarothra gentianoides* of Linnæus, *Hypericum Sarothra* of Purſh, very much in general habit. This and the two preceding have a great affinity to one another, but Mr. Purſh conſiders them good and permanent ſpecies, as there are no intermediate varieties, which might lead to a ſuſpicion that all belong to one genuine ſpecies. We have ſeen neither of the two laſt.

37. S. *cæſia.* Maryland Golden-rod. Linn. Sp. Pl. 1234. Willd. n. 27. Ait. n. 20. Purſh n. 33. (Virga aurea marilandica cæſia glabra; Dill. Elth. 414. t. 307. f. 395.)—Stem nearly erect, very ſmooth and even. Leaves lanceolate, ſmooth, with roughiſh edges and ribs. Cluſters erect.

Rays rather longer than the diſk.—In woods and low fields, from New England to Carolina, flowering from Auguſt to October. *Purſh.* The *ſtem* is upright, but ſomewhat zig-zag, branched, leafy, deſtitute of any furrows or other inequalities. *Leaves* about two inches long, pointed, nearly or quite entire, rather glaucous; paler beneath. *Cluſters* numerous, ſhort, with rough ſtalks, and ſmall, ſmooth, awl-ſhaped *bracteas.*

38. S. *livida.* Livid Golden-rod. Willd. Enum. 891. Purſh n. 34.—"Stem ſmooth, panicled. Leaves lanceolate, ſerrated, ſmooth, rough-edged. Branches racemoſe at the extremity. Rays elongated."—In ſandy fields and woods, from New York to Virginia, flowering in September and October. *Purſh.* *Stem* branched, dark purple, ſmooth. *Leaves* tapering at each end. Akin to *S. cæſia* in the colour of the *ſtem,* but different in having a panicled *ſtem,* whoſe *branches* are racemoſe at the ſummit. *Willdenow.* We are unacquainted with any thing anſwering to this deſcription.

39. S. *hiſpida.* Hiſpid Golden-rod. Willd. n. 28. Purſh n. 35.—"Stem erect, rough with briſtles. Leaves lanceolate, rough, entire; the radical ones ſerrated. Cluſters erect. Rays of a middling length."—In graſſy fields and woods, from New Jerſey to Virginia, flowering in October and November.—Reſembles *S. cæſia.* *Purſh.*

40. S. *hirta.* Hairy Golden-rod. Willd. Enum. 891. Purſh n. 36.—"Stem panicled, hairy. Leaves lanceolate, rough on both ſides; thoſe of the ſtem ſerrated; of the branches entire. Cluſters erect. Rays elongated."—Native of North America, according to Willdenow, on whoſe authority alone it finds a place in the work of Mr. Purſh. It is ſaid to be ſufficiently diſtinguiſhed by the hairy *ſtem,* and rough *leaves,* of which ſuch as grow on the principal ſtem are deeply and ſharply ſerrated.

41. S. *lithoſpermifolia.* Gromwell-leaved Golden-rod. Willd. Enum. 892. Purſh n. 37.—"Stem branched, downy. Leaves lanceolate, rough on both ſides, tapering, three-ribbed, entire. Cluſters erect. Rays elongated.—In ſandy barren woods, from New Jerſey to Carolina, flowering from Auguſt to October. *Purſh.* Willdenow ſays the *leaves* are much like *Lithoſpermum officinale.*

42. S. *lævigata.* Fleſhy-leaved Golden-rod. Ait. ed. 1. v. 3. 215. ed. 2. n. 21. Willd. n. 29. Purſh n. 38.—Stem erect, ſmooth. Leaves lanceolate, fleſhy, entire, ſmooth in every part. Cluſters panicled, erect. Flower-ſtalks ſcaly, hairy. Radius twice the length of the calyx.—In ſalt-marſhes, from Canada to Virginia, flowering from September to November.—A tall robuſt ſpecies, reſembling the following one very much, and probably nothing more than a variety. *Purſh.* This opinion ſeems to us very correct, there being really no difference between the two plants, except the hairineſs of the *flower-ſtalks* in the preſent, and its flowering about three months later than *S. mexicana.*

43. S. *mexicana.* Mexican Golden-rod. Linn. Sp. Pl. 1234. Willd. n. 30. Ait. n. 22. Purſh n. 39. (Virga aurea mexicana; Bauh. Pin. 517. V. aurea mexicana, limonii folio; Dodart. Mem. ed. Amſt. 629. t. 36.)—Stem oblique, ſmooth. Leaves lanceolate, ſomewhat fleſhy, entire, ſmooth in every part. Cluſters panicled, erect. Flower-ſtalks ſcaly, ſmooth. Rays longer than the calyx.—On the banks of rivers and ditches in North America, near ſalt-water, flowering from July to September.—Tall; *flowers* large. *Purſh.* This is ſmooth and even in every part, and of a rather fleſhy, ſomewhat glaucous habit, approaching to our *Aſter Tripolium,* whoſe place it occupies in America. The radical *leaves* are large, obovate, on long ſtalks. *Bracteas* numerous, lanceolate, keeled, recurved, of a thin, ſcaly, or ſquarroſe, aſpect, ſmooth, exactly like the laſt, but the *flower-ſtalks* are equally ſmooth, which in that are very rough with ſhort hairs. *Flowers* rather large.

44. S. *viminea.* Twiggy Golden-rod. Ait. ed. 1. v. 3. 215. ed. 2. n. 23. Willd. n. 31. Purſh n. 40. (S. integerrima; Mill. Dict. ed. 8. n. 24.)—Stem erect, ſlightly downy. Leaves linear-lanceolate, ſmooth, rough-edged; tapering at the baſe: the lower ones ſomewhat ſerrated. Cluſters erect. Rays elongated.—On the banks of rivers and ditches, from Canada to Virginia, flowering from Auguſt to October. *Purſh.*—Akin to the two laſt, but the *leaves* are thin or membranous, not ſucculent; their margin furniſhed with little inflexed rigid briſtles. *Flower-ſtalks* and *branches* angular and very rough. *Bracteas* lanceolate, recurved, ſmooth. *Flowers* numerous, the ſize of the preceding.

45. S. *erecta.* Erect Golden-rod. "Bankſ. MSS." Purſh n. 41.—"Stem rather villous. Leaves lanceolate, veiny, ſmooth, entire, ſomewhat ſtalked."—Native of North America. *Herb. Banks.* *Purſh.*

46. S. *macrophylla.* Long-leaved Golden-rod. "Bankſ. MSS." Purſh n. 42.—"Lower leaves ovate, pointed, tapering, unequally and ſharply ſerrated, ſmooth; thoſe of the ſtem lanceolate, tapering at each end, ſerrated, nearly ſeſſile. Cluſters axillary, ſtalked, leafy, the length of the leaves. Calyx oblong, turgid, many-flowered. Rays ſomewhat elongated."—In Canada. About three feet high. Intermediate between this genus and *Aſter.* *Purſh.*

47. S. *glomerata.* Round-headed Golden-rod. Michaux Boreal-Amer. v. 2. 117. Purſh n. 43.—"Stem low, quite ſimple. Leaves ſmooth, oblong-lanceolate, ſerrated. Cluſter ſimple, formed of round axillary heads; the uppermoſt crowded. Calyx turgid, many-flowered."—Found by Michaux on the mountains of Carolina. No other botaniſt ſeems acquainted with this ſpecies, nor is it eaſy to underſtand his definition of the leaves; ("*foliis longè latèque lanceolatis.*")

48. S. *flexicaulis.* Crooked-ſtalked Golden-rod. Linn. Sp. Pl. 1234. Willd. n. 32, α. Ait. n. 24, α. Purſh n. 44, α. (Virga aurea montana, ſcrophulariæ folio; Pluk. Phyt. t. 235. f. 3.)—Stem zig-zag, roundiſh, ſmooth. Leaves lanceolate, pointed, ſerrated, ſmooth, nearly ſeſſile. Cluſters axillary, erect.—In woods and fields, from Canada to Carolina, flowering from Auguſt to October. *Purſh.* The *ſtem* is ſlender, zig-zag, purpliſh, ſmooth and even; moſtly round; occaſionally ſomewhat angular. *Leaves* numerous, alternate, on very ſhort broad *ſtalks,* lanceolate, from one and a half to two inches long, half an inch wide, ſerrated, rough-edged, very ſmooth on both ſides; paler beneath, ſomewhat contracted and entire in their lower half; the upper ones ſometimes nearly entire. *Cluſters* much ſhorter than the leaves, oblong, with hairy *ſtalks,* and ovate, ſmooth, veiny *bracteas;* the upper ones very ſhort, and nearly capitate. *Radius* pale yellow, half as long again as the calyx.

49. S. *latifolia.* Broad-leaved Axillary Golden-rod. Linn. Sp. Pl. 1234. (S. flexicaulis β; Willd. n. 32. Ait. n. 24. Purſh n. 44. Virga aurea canadenſis aſteriſci folio; Herm. Parad. 244. t. 244.)—Stem ſomewhat zig-zag, angular, ſmooth. Leaves ovate, pointed, ſtrongly ſerrated, ſmooth; tapering into a winged footſtalk. Cluſters axillary, erect.—In woods and fields from Canada to Carolina, flowering from Auguſt to October. *Purſh.* Very different in appearance from the laſt, to which it is united by various authors, on the authority of the *Hortus Kewenſis.* But we ſuſpect the real *flexicaulis* is not much underſtood in England, what we have under that name from Kew garden, as well as the Bankſian herbarium, being really the *latifolia,* which latter ſpecies was not known, as ſuch, to the botaniſts

here, till the Linnæan herbarium came among them. How far it may be ſpecifically diſtinct, we cannot be certain. We have ſpecimens of both from the late Rev. Dr. Muhlenberg, whoſe *leaves* differ greatly. Thoſe of *latifolia* are two inches broad, with very copious, deep, acute ſerratures, and contract at the baſe, more or leſs ſuddenly, into a winged *footſtalk*, near an inch long. Their rib, and under ſide, are ſometimes hairy. Nothing like this is ſeen in *flexicaulis*. We ſuſpect Plukenet's t. 235. f. 4, as well as f. 3, may belong to this laſt; ſee the following. Hermann's plate is certainly *latifolia*. Mr. Purſh ſpeaks of theſe ſpecies collectively, as the moſt common *Solidago* in North America. We know not to which of the two this is moſt applicable.

50. S. *ambigua*. Angular-ſtalked Golden-rod. Ait. ed. 1. v. 3. 217. ed. 2. n. 25. Willd. n. 33. (Virga aurea latiſſimo folio, canadenſis, glabra; Pluk. Phyt. t. 235. f. 4?)—Stem ſlightly zig-zag, ſmooth, angular, branched. Leaves ovato-lanceolate, pointed, denſely ſerrated, rather hairy beneath; tapering into a winged footſtalk; upper ones entire. Cluſters axillary, erect; the upper ones much longer than the leaves.—Cultivated by Miller, and communicated from Kew garden to the younger Linnæus. It is ſaid to flower in July and Auguſt, but its native country is unknown, nor has Mr. Purſh met with this plant in America. It may be a variety of *latifolia*, from which it differs in having ſomewhat narrower *leaves*, and in the much greater length of the upper cluſters of *flowers*, which combine to form a cloſe panicle. Plukenet's figure, cited here with doubt, does not quite enough expreſs this, nor are ſo many of the leaves entire, though ſeveral of the upper ones are ſo in our ſpecimen.

51. S. *alpeſtris*. Alpine Golden-rod. "Waldſt. and Kitaib. Hung." Willd. n. 34.—"Stem erect, ſmooth. Leaves elliptic-lanceolate; the lower ones ſerrated. Cluſters erect, cloſe, ſhorter than the leaves. Rays elongated."—Native of the Carpathian, Auſtrian, and Bohemian alps. Very like the following, but the *ſtem-leaves* are elliptic-lanceolate, nearly entire, and the *ſtem* is ſmooth. It varies greatly by culture, becoming two feet, inſtead of one, in height, and branched, inſtead of quite ſimple. The *leaves* of the wild plant meaſure from half an inch to an inch and a half, (we preſume in length); thoſe of the garden one from one and a half to three inches. The upper *cluſters* of the former are crowded into a ſort of ſpike; thoſe of the latter are axillary, and compoſed of few *flowers*. *Willdenow*.

52. S. *Virgaurea*. Common Golden-rod. Linn. Sp. Pl. 1235. Willd. n. 35. Ait. n. 26. Purſh n. 46. Fl. Brit. n. 1. Engl. Bot. t. 301. Fl. Dan. t. 663. (S. n. 69; Hall. Hiſt. v. 1. 29. Virga aurea; Ger. Em. 430. Camer. Epit. 748, 749. Matth. Valgr. v. 2. 354.)

β. Virga aurea, longo, molli, et lanceolato folio, alpina; Bocc. Muſ. 34. t. 30.

γ. Virga aurea montana minor; Bocc. Muſ. 169. t. 118. Barrel. Ic. t. 783.

δ. Solidago cambrica; Hudſ. 367. Ait. n. 27. Willd. n. 36. (Virga aurea cambrica, floribus conglobatis; Dill. Elth. 413. t. 306. f. 393.)

ε. S. minuta; Linn. Sp. Pl. 1235. Willd. n. 38. Ait. n. 29. (Virga aurea omnium minima, floribus maximis; Herm. Parad. 245. t. 245. V. aurea montana biuncialis pumila, foliis acuminatis; Pluk. Phyt. t. 235. f. 7; and foliorum apicibus obtuſis; f. 8.)

Stem ſomewhat zig-zag, angular, hairy. Leaves more or leſs ſerrated, roughiſh; tapering at the baſe. Cluſters panicled, erect, cloſe. Rays twice the length of the calyx. —Native of buſhy, heathy, mountainous, and alpine ſituations throughout Europe, as well as at Labrador, and even China, flowering in the latter part of ſummer. The *root* is perennial, conſiſting of long ſimple fibres. *Stem* very variable in height and luxuriance, moſtly from one to three feet high, and branched in a panicled manner, more or leſs zig-zag, never quite ſtraight, leafy, angular, covered more or leſs with ſhort hairs, eſpecially the upper part; rounder, and frequently purpliſh, at the baſe. *Leaves* elliptic-lanceolate, or nearly ovate, roughiſh, firm and rather rigid; the lower ones ſtalked; the reſt variouſly elongated at the baſe; all extremely variable in ſize, and eſpecially in their ſerratures, which, though commonly cloſe and ſhallow, are ſometimes very coarſe and tooth-like, ſometimes nearly wanting; the margin is always rough with minute briſtly hairs; the ſurface ſmooth or rough; the under ſide rather paler; ſometimes the upper *leaves* are recurved, or drooping, and the uppermoſt of all gradually diminiſh into *bracteas*. *Panicle* terminal, many-flowered, attended by ſmall leaves; its lower branches often axillary; all downy, racemoſe, or corymboſe; now and then ſimple and ſingle-flowered. Scales of the *calyx* at length ſpreading, but all ſtraight, imbricated, lanceolate, fringed, membranous at the edges; ſometimes rough at the back. *Florets* of the radius from five to nine or ten, of a golden yellow, ſpreading, elliptic-oblong, toothed at the end, their limb the length of the calyx.—We ſcarcely know a plant more difficult to define or to underſtand than this, nor can we limit even the varieties ſo as to make them intelligible; much leſs elevate them to the rank of ſpecies. β, ſent from Italy by Arduino to Linnæus, is more downy, with more pliant *leaves*, than our common kind, with numerous axillary *cluſters*, and a more leafy *panicle*. The *flowers* are conſiderably larger than uſual.

γ has equally large *flowers*, but much fewer, ſo that the *pancicle* is nearly ſimply racemoſe, and the *leaves* are coarſely ſerrated. We have Swiſs ſpecimens of Haller's n. 69, which combine theſe two varieties, and whoſe herbage connects them with the common ſtate of the ſpecies.

δ is equally ſimple in its *panicle*, and its growth is more humble, but the moſt authentic ſpecimens prove it a mere variety. It is impoſſible to ſay what Willdenow had for *S. cambrica*, which he aſſerts to remain unchanged by culture; but his authority falls to the ground, ſince he perſiſts in quoting Petiver's t. 16. f. 11, which we have pointed out in Fl. Brit. as a copy of Camerarius, t. 748, done for the common *Virgaurea!*

ε is the moſt puzzling of all. The *flowers* in Hermann's plate nearly equal thoſe of our β; while in the Linnæan ſpecimen, evidently, as Linnæus judged it, a variety of *Virgaurea*, they are but half as large, and panicled. This ſpecimen was ſent by Arduino for Boccone's t. 118, (ſee variety γ,) which it very little reſembles. Plukenet's figures have the chiefly axillary infloreſcence of our β, only each ſtalk is ſimple, not racemoſe.—If any of theſe varieties are to be eſtabliſhed as ſpecies, it muſt be from far better materials than have fallen in our way, and by widely different characters than have as yet been given. We muſt obſerve that Grew's t. 59, cited by Haller, is evidently one of the garden American ſpecies, totally unlike *Virgaurea*.

53. S. *multiradiata*. Labrador Golden-rod. Ait. ed. 1. v. 3. 218. ed. 2. n. 28. Willd. n. 37. Purſh n. 47.—"Stem rather villous. Leaves ſeſſile, lanceolate, ſmooth, fringed; the lower ones ſerrated at the end. Cluſter terminal, erect. Rays numerous, elongated."—Found at Labrador and Hudſon's Bay, flowering from Auguſt to October.—*Purſh*.—*Stem* a ſpan high, downy, erect, quite ſimple. *Leaves* narrow, nearly entire. *Cluſter* denſe. *Radius* narrow, copious. *Willdenow*.

54. S. *humilis*. Humble Golden-rod. Purſh n. 48.—“Stem ſimple, erect, ſmooth. Leaves lanceolate, ſerrated, ſmooth; tapering and elongated at the baſe. Cluſter erect.”—Native of North America, according to the Bankſian herbarium. *Purſh*.

55. S. *elata*. Lofty Golden-rod. Purſh n. 49.—“Stem hairy, round. Leaves lanceolate; rather hairy beneath. Cluſters erect. Rays elongated.”—Native of North America, according to the ſame authority. *Purſh*.

56. S. *rigida*. Hard-leaved Golden-rod. Linn. Sp. Pl. 1235. Willd. n. 39. Ait. n. 30. Purſh n. 50. (Virga aurea Novæ Angliæ, lato rigido folio; Herm. Parad. 243. t. 243.)—Leaves ovate-oblong, rough, like the corymboſe ſtem, with minute rigid hairs; the lowermoſt ſerrated; upper entire. Cluſters compact. Rays twice the length of the obtuſe calyx.—In the tract of mountains from New Jerſey to Carolina, flowering from Auguſt to October. *Purſh*. The *ſtem* is four or five feet high, round, ſtriated, leafy, rough with copious rigid pubeſcence, and branched copiouſly, in a corymboſe manner, at the top. *Leaves* rough like a file, ſomewhat hoary; the radical ones ſtalked, a foot long, broad, pointed, ribbed, more or leſs ſerrated; the reſt from one to four inches long, either obtuſe or ſomewhat pointed, entire, or occaſionally crenate; thoſe on the flowering branches numerous, ſmall, and entire. *Flowers* rather large, but various in ſize. Scales of the *calyx* blunt, or rounded at the end, ribbed, membranous at the edge, variable in breadth.—A Pennſylvanian ſpecimen, ſent by the late Dr. Muhlenberg, has crenate, exactly ovate, *leaves* on the ſtem, and *flowers* about half the uſual ſize; but we dare not make it a diſtinct ſpecies.

57. S. *noveboracenſis*. New York Golden-rod. Linn. Sp. Pl. 1235. Willd. n. 40. Purſh n. 51.—Radical leaves elliptic-oblong, ſtalked, rough. Stem almoſt naked, branched, furrowed, level-topped. Rays twice as long as the taper-pointed calyx.—In ſandy fields and woods of North America, flowering in September and October. *Purſh*. The *root* is thick and ſomewhat woody. *Stem* one and a half or two feet high, ſtout, rough, round, plentifully furrowed, quite erect, bearing two or three oblong-lanceolate leaves at the origin of the flowering branches, but otherwiſe naked. *Leaves* chiefly radical, on long, erect ſtalks, elliptical, tapering at each end, three inches long, rough like a file with minute tubercles, the margin furniſhed with ſhallow ſerratures. *Flowers* large, not numerous, on corymboſe hairy ſtalks, with a few rough lanceolate *bracteas*. *Calyx-ſcales* narrow, purpliſh, downy, with long tapering points. The radiant *florets* appear to be ſometimes more than ten. The *ſeeds* are hairy; their down long, very ſlender, minutely rough. This ſpecies appears to be a ſtranger in our gardens. Its habit is that of an *Aſter*.

Solidago, in *Gardening*, contains plants of the tall, herbaceous, flowering, perennial kind, of which the ſpecies cultivated are; the common golden-rod (S. virgaurea); the Canadian golden-rod (S. canadenſis); the tall golden-rod (S. altiſſima); the Mexican golden-rod (S. mexicana); the twiggy golden-rod (S. viminea); the two-coloured golden-rod (S. bicolor); the hard-leaved golden-rod (S. rigida); the Maryland golden-rod (S. cæſia); the crooked-ſtalked golden-rod (S. flexicaulis); and the narrow-leaved evergreen golden-rod (S. ſempervirens).

The firſt ſort has ſometimes the names of Wound-wort and Aaron's rod. There are ſeveral varieties of it, as the purple-ſtalked broad-leaved, which has the ſtalks ſtiff, purpliſh-brown, two feet high: the panicles axillary and terminating; each flower on a long ſlender footſtalk, pale yellow, appearing at the beginning of Auguſt; the leaves lanceolate, almoſt four inches long, and a quarter of an inch broad, deeply ſerrate, pale green beneath.

The common golden-rod, which has the lower leaves ovate-lanceolate, two inches long and an inch broad, ſlightly ſerrate, on pretty long footſtalks; the ſtems ſlender, a foot and a half high; with ſmall, narrow, entire, ſeſſile leaves; the flowers in panicled bunches, cluſtered together, forming a thick erect ſpike, appearing in Auguſt and September. The narrow-leaved, which has the ſtalk round, ſmooth, a foot and a half high; the leaves narrow-lanceolate, an inch and a quarter long, and an eighth of an inch broad, almoſt entire, ſeſſile; the flowers in ſmall cluſtered bunches from the axils, to which they ſit very cloſe; and the ſtalk is terminated by a roundiſh bunch. The dwarf golden-rod, which has the lower leaves indented; the ſtalk ſeldom more than a foot high, branching out almoſt from the bottom; the branches terminated by ſhort, cluſtered, erect ſpikes; the leaves on the ſtem and branches very narrow, acute-pointed, and entire. The Welſh golden-rod, which has the lower leaves narrow-lanceolate, an inch and half long, and a quarter of an inch broad, ſmooth, ſlightly ſerrate, a little hoary on the under ſide; the ſtalk about ſix inches high, with the ſame ſort of leaves on it, only ſmaller; the flowers in roundiſh cluſtered terminating ſpikes, much larger than thoſe of the common ſort, and appearing five or ſix weeks earlier in the ſeaſon.

In the third ſort there are ſeveral varieties; as the talleſt golden-rod, the hairy golden-rod, the recurved golden-rod, the Virginia golden-rod.

Method of Culture.—Theſe plants are all readily increaſed by ſlipping or parting the roots, and planting them out in the autumn or winter ſoon after their ſtems decay, or very early in the ſpring before they begin to ſhoot, but the former is the better ſeaſon, in the places where they are to grow; they ſucceed in almoſt any ſoil or ſituation, and afterwards require only to be kept clean from weeds, and to have the decayed ſtems cut down when they begin to decay in the autumn. When they have increaſed conſiderably in the roots, they ſhould always be ſlipped as above.

Theſe plants are very hardy and durable in their roots, by which moſt of them ſoon become large, the ſmall ſlips not unfrequently growing into large bunches in one ſeaſon, many of them, of courſe, require to be well cut in with a ſharp ſpade all round about their roots annually, or nearly ſo, to prevent their ſpreading too greatly and having an improper appearance, as well as being injurious to other neighbouring plants of ſmall growth.

In planting out they require much room, as they ſpread conſiderably. But they afford conſiderable variety and ornament in larger borders and clumps, on all pleaſure-grounds towards the autumnal ſeaſon.

Solidago, in the *Materia Medica*. The flowers and the leaves of the common golden-rod, or virga aurea, have a ſlightly aromatic odour, and a ſubaſtringent ſomewhat aromatic taſte. Boiling water extracts the active matter. The infuſion changes ſlightly to green ſyrup of violets, and precipitates ſulphate of iron black. Golden-rod is aſtringent, and has been regarded as lithontriptic. It may be, ſays Thomſon (Diſp.), of ſome uſe in a weakened ſtate of the viſcera, and, like other tonics, beneficial in calculous habits, but it is not entitled to much notice. The doſe of the powdered leaves and flowers may be from grs. x to ʒj or more.

SOLIDAR, in *Geography*, a town of Bengal; 26 miles S.S.W. of Rogonatpour.

SOLIDITY, in *Phyſics*, a property of matter or body, by which it excludes every other body from that place which itſelf poſſeſſes.

Solidity, in this ſenſe, is a property common to all bodies, whether ſolid or fluid. It is uſually called *impenetrability;* but ſolidity expreſſes it beſt, as carrying ſomewhat more of poſitive with it than the other, which is a negative idea.

The idea of ſolidity, Mr. Locke obſerves, ariſes from the reſiſtance we find one body make to the entrance of another into its own place. Solidity, he adds, ſeems the moſt extenſive property of body, as being that by which we conceive it to fill ſpace; it is diſtinguiſhed from mere *ſpace*, by this latter not being capable of reſiſtance or motion.

It is diſtinguiſhed from *hardneſs*, which is only a firm coheſion of the ſolid parts, ſo as they may not eaſily change their ſituation.

The difficulty of changing ſituation gives no more ſolidity to the hardeſt body than to the ſofteſt; nor is a diamond properly a jot more ſolid than water. By this we diſtinguiſh the idea of the extenſion of body from that of the extenſion of ſpace: that of body is the continuity or coheſion of ſolid, ſeparable, moveable parts; that of ſpace, the continuity of unſolid, inſeparable, immoveable parts.

The Carteſians, however, will, by all means, deduce ſolidity, or, as they call it, *impenetrability*, from the nature of extenſion; they contend that the idea of the former is contained in that of the latter; and hence they argue againſt a vacuum. Thus, ſay they, one cubic foot of extenſion cannot be added to another, without having two cubic feet of extenſion; for each has in itſelf all that is required to conſtitute that magnitude. And hence they conclude, that every part of ſpace is ſolid, or impenetrable, inaſmuch as of its own nature it excludes all others. But the concluſion is falſe, and the inſtance they give follows from this, that the parts of ſpace are immoveable, not from their being impenetrable or ſolid.

For an account of a late controverſy concerning the ſolidity of matter, ſee MATTER.

SOLIDITY, in *Geometry*, the quantity of ſpace contained in a ſolid body; called alſo the *ſolid content*, and the cube of it.

The ſolidity of a cube, priſm, cylinder, or parallelepiped, is had by multiplying its baſis into its height.

The ſolidity of a pyramid or cone is had by multiplying either the whole baſe into a third part of the height, or the whole height into a third part of the baſe.

SOLIDITY *of any irregular Body, To find the.* Put the body in a hollow parallelepiped, and pour water or ſand upon it, and note the height of the water or ſand A B (*Plate* XIV. *Geometry*, *fig.* 2.); then taking out the body, obſerve at what height the water (or ſand, when levelled) ſtands, as A C. Subtract A C from A B, the remainder will be B C. Thus is the irregular body reduced to a parallelepiped, whoſe baſe is F C G E, and its altitude B C. To find the ſolidity of which, ſee PARALLELEPIPED.

Suppoſe, *e. gr.* A B to be 8, and A C, 5; then will B C be 3: ſuppoſe, again, D B, 12, D E, 4; then will the ſolidity of the irregular body be found 144.

If the body be ſuch as that it cannot be well laid in ſuch a kind of channel, *e. gr.* if it be required to meaſure the ſolidity of a ſtatue, as it ſtands; a quadrangular priſm or parallelepiped is to be framed over it; the reſt as before.

SOLIDITY *of a hollow Body, To find the.* If the body be not compriſed in the number of regular bodies, its ſolidity is found as in the preceding problem. If it be a parallelepiped, priſm, cylinder, ſphere, pyramid, or cone, the ſolidity firſt of the whole body, including the cavity, then that of the cavity, which is ſuppoſed to have the ſame figure with the body itſelf, is to be found, according to the reſpective methods delivered under PARALLELEPIPED, PRISM, &c. For the latter being ſubtracted out of the former, the remainder is the ſolidity of the hollow body required.

For the centrobaryc method of meaſuring the ſolidity of bodies, ſee CENTROBARYC *Method.*

To find the Solidity of Bodies by the Method of Fluxions. Let A B C (*Plate* XIV. *Analyſis*, *fig.* 1.) repreſent any ſolid conceived to be generated by a plane P Q, paſſing over it with a parallel motion: let H h, perpendicular to P Q, be taken to expreſs the fluxion of A H (x), or the velocity with which the generating plane is carried: alſo let the area of the part E m F n be denoted by A: then it follows, from the definition of a fluxion, that the fluxion of the ſolid A E F will be expreſſed by A $\dot{x}$. Whence, by expounding A in terms of x (according to the nature of the figure), and then taking the fluent, the contents of the ſolid, which we may repreſent by s, will be given. But, when the propoſed ſolid is that ariſing from the revolution of any given curve A E B about A H D, as an axis, the fluxion ($\dot{s}$) of the ſolidity may be exhibited in a manner more convenient for practice; for, putting the area (3.141592, &c.) of the circle, whoſe radius is unity, $= p$, and the ordinate E H $= y$, it will be $1^2 : y^2 :: p : py^2$, the area of the circle E m F n, which being ſubſtituted for A, we have $\dot{s} = py^2 \dot{x}$.

Ex. 1. *To find the Content of a Cone* A B C (*fig.* 2.) Let the given altitude A D be $= a$, and the ſemidiameter of its baſe B D $= b$, and the diſtance A F of the circle E G from the vertex A, $= x$; then we ſhall have, by ſimilar triangles, $a : b :: x :$ E F $(y) = \frac{bx}{a}$. Whence $\dot{s}\ (= py^2\dot{x}) = \frac{pb^2 x^2 \dot{x}}{a^2}$; and, conſequently, by the inverſe method of fluxions, $s = \frac{pb^2 x^3}{3a^2}$; which, when $x = a$ (= A D), gives $\frac{pb^2 a}{3} = p \times$ B D$^2 \times \frac{1}{3}$ A D for the content of the whole cone A B C; which appears, from hence, to be juſt $\frac{1}{3}$d of a cylinder of the ſame baſe and altitude. See CONE.

Ex. 2. *To find the Content of a Spheroid* A F B H (*fig.* 3.) *and alſo of a Sphere.* Let the axis A B, about which the ſolid is generated, be $= a$, and the other axis F H of the generating ellipſe $= b$; it follows, from the property of the ellipſe, that $a^2 : b^2 :: x\ (a - x)$ (A D × B D) $: y^2$ (D E^2) $= \frac{b^2}{a^2}(ax - xx)$: whence we have $s = (py^2\dot{x} =) \frac{pb^2}{a^2}(ax\dot{x} - x^2\dot{x})$, and $s = \frac{pb^2}{a^2}(\frac{1}{2}axx - \frac{1}{3}x^3)$ = the ſegment A I E. Which, when A D (x) = A B (a), becomes $\frac{pb^2}{a^2}(\frac{1}{2}a^3 - \frac{1}{3}a^3) = \frac{pb^1}{a^2} \times \frac{a^3}{6} = \frac{1}{6}pab^2$ = the content of the whole ſpheroid. Where, if b (F H) be taken $= a$ (A B), we ſhall obtain $\frac{1}{6}pa^3$ for the true content of a ſphere whoſe diameter is a. Hence, a ſphere, or a ſpheroid, is $\frac{2}{3}$ds of its circumſcribing cylinder; for the area of the circle F H being expreſſed by $\frac{pb^2}{4}$, the content of the cylinder, whoſe diameter is F H, and altitude A B, will, therefore, be $\frac{pb^2a}{4}$, of which $\frac{1}{6}pab^2$ is evidently two third parts. See SPHERE and SPHEROID.

Ex. 3. *To find the Content of a parabolic Conoid.* From the equation $a^{m-n}\,x^n = y^m$ of the generating curve, we obtain $y = a^{\frac{m-n}{m}} \times x^{\frac{n}{m}}$, and $\dot{s}\ (= py^2\dot{x}) = pa^{\frac{2m-2n}{m}} \times \dot{x}x^{\frac{2n}{m}}$; and, therefore, $s = pa^{\frac{2m-2n}{m}} \times \frac{x^{\frac{2n}{m}+1}}{\frac{2n}{m}+1} = pa^{\frac{2m-2n}{m}} \times \frac{mx^{\frac{2n}{m}+1}}{2n+m} = pa^{\frac{2m-2n}{m}} \times x^{\frac{2n}{m}} \times \frac{mx}{2n+m}$ $= py^2 \times \frac{mx}{2n+m} =$ the content of the ſolid; which, therefore, is to py^2x, the content of the circumſcribing cylinder, as m to $2n + m$. Whence the ſolid generated by the conical parabola (in which $m = 2$, and $n = 1$) appears to be juſt half of its circumſcribing cylinder. See PARABOLIC *Conoid.*

Ex. 4. *To find the Content of an hyperbolic Conoid.* From the equation $y^2 = \frac{b^2}{a^2}(ax + xx)$ of the generating hyperbola, we have $\dot{s}\ (py^2\dot{x}) = \frac{pb^2}{a^2}(ax\dot{x} + x^2\dot{x})$, and conſequently $s = \frac{pb^2}{a^2}(\frac{1}{2}ax^2 + \frac{1}{3}x^3) =$ the content of the conoid; which, therefore, is to $\left(\frac{pb^2}{a^2}(ax + x^2)x\right)$ that of a cylinder of the ſame baſe and altitude, as $\frac{1}{2}a + \frac{1}{3}x$ to $a + x$. This ratio, if x be very ſmall, will become as 1 to 2 very nearly: whence it may be inferred, that the content of a very ſmall part of any ſolid generated by a curve, whoſe radius of curvature at the vertex is a finite quantity, is half that of a cylinder of the ſame baſe and altitude very nearly; becauſe any ſuch curve, for a ſmall diſtance, will differ inſenſibly from an hyperbola, whoſe radius of curvature, at the vertex, is the ſame.

Ex. 5. *To find the Content of a parabolic Spindle, generated by the Rotation of a given Parabola* A C B (*fig.* 4.) *about its Ordinate* A B. Put C M, the abſciſſe of the given parabola, $= a$, and the ſemi-ordinate A M (or B M) $= b$; and ſuppoſing E N F to be any ſection of the ſolid parallel to D C, let its diſtance M N or E P from D C be denoted by w: then, by the property of the curve, we ſhall have $AM^2\,(b^2) : EP^2\,(w^2) :: CM\,(a) : CP = \frac{aw^2}{b^2}$: therefore $EN\ (= CM - CP) = a - \frac{aw^2}{b^2} = \frac{a(b^2 - w^2)}{b^2}$, and conſequently $p \times EN^2 = \frac{pa^2}{b^4}(b^4 - 2b^2w^2 + w^4)$ $=$ the area of the ſection E F: which, multiplied by $\dot{w}$, the fluxion of M N, gives $\frac{pa^2}{b^4}(b^4\dot{w} - 2b^2w^2\dot{w} + w^4\dot{w})$ for the fluxion of the ſolidity, whoſe fluent $\frac{pa^2}{b^4}(b^4w - \frac{2}{3}b^2w^3 + \frac{2}{5}w^5)$, when w becomes $= b$, is $\left(\frac{8pa^2b}{15}\right)$ half the content of the ſolid. See PYRAMIDOID.

For other examples of a ſimilar kind, ſee Simpſon's Fluxions, vol. i. ſect. 9, and other elementary treatiſes on that ſubject.

SOLIDITY, in *Architecture*, is applied both to the conſiſtence of the ground on which the foundation of a building is laid, and to a maſs of maſonry of extraordinary thickneſs, without any cavity within. The ſolidity of the Egyptian pyramids is inconceivable.

SOLIDS, in *Anatomy*, &c. denote all the continuous and continent parts of the body; thus called, in oppoſition to the fluids, or parts contained in them.

Of the ſolid kind, are the bones, cartilages, ligaments, membranes, fibres, muſcles, tendons, arteries, veins, nerves, glands, lympheducts, and lacteals.

SOLIDUS, in *Ancient Coinage.* (See AUREUS.) According to Pliny's account, gold was coined at Rome ſixty-two years after ſilver, *i. e.* 547 U. C. or B. C. 204; and then the ſcruple paſſed, as he informs us, for 20 ſeſterces. It was afterwards thought proper to coin 40 pieces out of the pound of gold; and, as he ſays, our princes have, by degrees, diminiſhed their weight to 45 in the pound. The pieces that now remain confirm Pliny's account. In the firſt coinage, the aurei were 48 in the pound; afterwards, as Pliny ſays, there were 40 in the pound, and the aureus was raiſed from 106 grains, the weight of the didrachm of this coinage, to 126 grains. From Pliny and the coins it appears, that in the firſt coinage, the ſcruple of gold paſſed for 20 ſeſterces; the drachm of three ſcruples was 60 ſeſtertii, or 15 ſilver denarii; and the didrachm, or aureus, the common Roman gold coin, was worth 30 ſilver denarii, equal to 1*l.* ſterling; gold being to ſilver as 17½ to 1. The aureus ſeems to have continued at 30 ſilver denarii till Sylla's time; but about the year of Rome 675, B. C. 77, the aureus fell to the rate of 40 in the pound, as Pliny informs us, and being reduced near the ſcale of the Greek χρυσος, paſſed for 20 denarii, as the later for 20 drachmas, being in currency 13*s.* 4*d.* Engliſh. This is the more probable, becauſe we know from Suetonius, that the great Cæſar brought ſo much gold from Gaul, that it ſold at 3000 nummi a pound, that is, nine times its weight in ſilver; but the Gallic gold was of a very baſe ſort. However, in the reign of Claudius, the aureus paſſed for 100 ſeſtertii, or 25 ſilver denarii; at which rate it remained. This was 16*s.* 8*d.* Engliſh in currency; but valuing gold at 4*l.* an ounce, the intrinſic value of the aureus is about 1*l.* The aureus fell by degrees, as Pliny ſays, to 45 in the pound. From the coins it is clear, that it was in the time of the civil wars of Otho and Vitellius, that the aureus fell from 40 in the pound, or about 125 troy grains at a medium, to 45 in the pound, or about 110 grains of medial weight each. It continued of this ſtandard till the time of Elagabalus, when it fell to about 92 grains at an average, or near 55 in the pound. That the aureus paſſed for 25 ſilver denarii down to Alexander Severus, is clear; and ſuppoſing that ſtandard to remain, as we have no authority for a change till the time of Conſtantine I., the double aureus will have borne 50 ſilver denarii, and the aureus 25. The "triens" muſt have had eight ſilver denarii, and two denarii aurei; and the double triens, 16 ſilver denarii or argentei, and four denarii aurei. The denarius was not then worth above 14*s.* Engliſh. The only change Aurelian made in the money, was probably reſtricted to the gold; for it is certain that under him, and his ſucceſſor Probus, the common gold piece, or aureus, is of 100 grains, a ſize confined to theſe two emperors. There are alſo halves of about 50 grains; and double aurei, commonly of very fine workmanſhip, of upward of 200 grains. Down to

Conſtantine I., the aureus ſtands at between 80 and 70 grains. This prince, who ſeems not to have altered the ſize of the coin, inſtead of the “aureus,” gave the “ſolidus” of ſix in the ounce of gold, and cauſed it to paſs for 14 of his new ſilver coins, called “Milliarenſes,” and 25 denarii, as before; gold being to ſilver as about 14 to 1. The ſolidus, or chief gold coin, continued of the ſame ſtandard to the very cloſe of the Byzantine empire; for gold was common in Conſtantinople, while ſilver became more and more ſcarce. The ſolidus was worth 12*s.* ſterling. In the days of the firſt emperors the aureus was worth 25 denarii, and gold to ſilver about 13½ to 1. The medial aureus was 110 grains, the denarius 60. That ſtandard remained the ſame till the time of Alexander Severus, after which we have no data; but it is probable that Conſtantine took the value as he found it, and that from Alexander Severus to Conſtantine, if we except the ſhort interval of the end of Aurelian's reign, and beginning of that of Probus, gold was riſing in value till it exceeded 14 to 1. The gold coins, called “Bezants” in Europe, becauſe they were ſent from Byzantium, or Conſtantinople, were ſolidi of the old ſcale, ſix to the ounce. In Byzantine writers, the ſolidus is alſo called “Nomiſma,” or *the coin;* “Cryſinos,” becauſe of gold; “Hyperperos,” from its being refined with fire, or from its being of bright gold flaming like fire. The ſolidi alſo, like the aurei formerly, received names from the princes whoſe portraits they bore; as “Michelati,” “Manuelati.” Solidus is a term uſed for the aureus by Apuleius (Met. lib. 10.) who lived in the time of Antoninus the philoſopher; nay, ſo early as in the Prætorian edicts of the time of Trajan; being thus diſtinguiſhed from the ſemiſſis or half. In the time of Valerian, when aurei of different ſizes had been introduced, it became neceſſary to diſtinguiſh the particular aurei that were meant.

In the firſt gold coinage at Rome, the aureus was divided into four inferior parts: the ſemiſſis, or half, of 60 ſeſtertii; the tremiſſis, or third, of 40; the fourth, the name of which is not known, of 30; and the ſixth, or ſcrupulum, of 20. But ſoon afterwards all theſe were dropped, except the ſemiſſis or half, which occurs in the times of the conſuls, and of ſome emperors, but is extremely ſcarce, ſo that few muſt have been ſtruck. This gold ſemiſſis, or half aureus, is termed “quinarius” by medalliſts with great propriety, and is very uncommon in all the conſular and imperial times; but continued the only diviſion of the aureus till the time of Alexander Severus. This prince, as Lampridius informs us, coined ſemiſſes and tremiſſes of gold; but none have yet been found. It is likely they were all recoined by his immediate ſucceſſors, who again raiſed the tributes. He alſo propoſed to iſſue quartarii, but did not live to accompliſh his purpoſe. Trientes, or tremiſſes, of gold are, however, mentioned in reſcripts of Valerian I., and actually exiſt, both of him and of his ſon Gallienus, weighing about 30 grains. The gold tremiſſis was the pattern of the early French and Spaniſh gold coins; as the ſilver denarius, in its diminiſhed ſtate, was that of the Gothic and Saxon penny. Pinkerton's Medals, vol. i.

SOLIEK ELSEID, in *Geography*, a town of Egypt, on the left bank of the Nile; 10 miles S. of Girgé.

SOLIFO, a town of Naples, in the province of Otranto; 9 miles E. of Nardo.

SOLIGNAC-*ſur-Loire*, a town of France, in the department of the Upper Loire, and chief place of a canton, in the diſtrict of Le Puy; 13 miles S. of Le Puy. The town contains 880, and the canton 4455 inhabitants, on a territory of 150 kiliometres, in 6 communes.

SOLIGNY, a town of France, in the department of the Orne; 6 miles N. of Mortagne.

SOLIGO, a town of Italy, in the Treviſan; 6 miles S.W. of Trevigio.

SOLIHULL, commonly pronounced *Silhill*, is ſituated in the diviſion of the ſame name, in the hundred of Hemlingford, and county of Warwick, England. It is conſidered as a market-town, but the market is now in abſolute diſuſe. Its diſtance from Birmingham is 7 miles, and from London 108 miles. Dugdale conjectures that the chief parts of the diſtrict, now included in the pariſh of Solihull, were known by the name of Ulverlei, at the time of the Norman ſurvey. Here was formerly the principal ſeat of the barony of Limeſie; and the reſidence of the barons he ſuppoſes to have occupied a ſpot at preſent called Olton, a ſmall village about two miles north-weſt from Solihull. From the ruins of this baronial reſidence, and its dependent habitations, the town of Solihull is conjectured to have ariſen. Grants for an annual fair and a weekly market were ſpeedily procured; but the town does not appear to have obtained much diſtinction at any period. It bears the tranquil appearance of a large village, and contains little to attract the notice of travellers, except the church, which is a ſpacious edifice of the cruciform deſcription. In the population return of the year 1811, the pariſh is ſtated to contain 528 houſes, occupied by 2581 perſons.

On an elevated ſcite in the vicinity of Solihull, ſurrounded by ſpacious grounds, is Malvern-Hall, the manſion of Henry Greſwold Lewis, eſq. Dugdale's Antiquities of Warwickſhire. Beauties of England and Wales, vol. xv. Warwickſhire, by J. N. Brewer.

SOLIKAMSK, a town of Ruſſia, in the government of Perm, on the Kama, famous for its ſalt-works; 112 miles N. of Perm. N. lat. 59° 36′. E. long. 56° 13′.

SOLILOQUY, SOLILOQUIUM, a reaſoning, or diſcourſe, which a man holds with himſelf.

Papias ſays, that ſoliloquy is properly a diſcourſe by way of anſwer to a queſtion that a man has propoſed to himſelf.

Soliloquies are become very common things on the modern ſtage; yet can nothing be more inartificial, or more unnatural, than an actor's making long ſpeeches to himſelf, to convey his intentions, &c. to the audience.

Where ſuch diſcoveries are neceſſary to be made, the poet ſhould rather take care to give the dramatic perſons ſuch confidants, as may neceſſarily ſhare their inmoſt thoughts; by which means, they will be more naturally conveyed to the audience. Yet is even this a ſhift an accurate poet would not be found to have occaſion for.

The uſe and abuſe of ſoliloquies is well delivered by the duke of Buckingham, in the following lines:

> “Soliloquies had need be very few,
> Extremely ſhort, and ſpoke in paſſion too.
> Our lovers talking to themſelves, for want
> Of others, make the pit their confidant:
> Nor is the matter mended yet, if thus
> They truſt a friend, only to tell it us.”——

SOLIMAGUE, in *Geography*, a ſmall iſland near the weſt coaſt of Luçon. N. lat. 18° 3′. E. long. 120° 36′.

SOLIMAN, a country of Africa, near the ſource of the Gambia.—Alſo, a town of Tunis, the environs of which are inhabited by the deſcendants of the Moors, driven out of Spain, who preſerve their ancient manners and language, and are more honeſt than other Africans; 20 miles E.S.E. of Tunis.

SOLIMAN, *Bay of*, a bay on the weſt coaſt of Africa, in the ſtrait of Babel-Mandeb. N. lat. 12° 3′.

SOLIMENE, Francesco, called alſo *L'Abate Ciccio*, in *Biography*, was born at Nocera de Pagani, near Naples, in 1637. He was the ſon of a painter, Angelo Solimene, who at firſt educated him in literary purſuits, in which he was exceedingly aſſiduous, and made conſiderable progreſs; whilſt at the ſame time he indulged himſelf in cultivating an inherent taſte for deſign. By the advice of cardinal Orſini, Franceſco was permitted by his father to change the object of his principal purſuit, and, inſtead of the law, to adopt the pencil, as the ground-work of his future fame. He became the diſciple of Franceſco Maria, and afterwards of Giacomo del Po; but ſoon left Naples, to go to Rome, where the freedom and brilliancy of Pietro da Cortona's execution and deſign attracted his admiration, and fixed his attention. To what he acquired of Cortona, he attempted to add the ſweetneſs of Guido Rheni; and thus framed for himſelf a ſtyle remarkable for its eaſe and ſuavity, more than for its grace or truth. A very beautiful production of his is at Hampton Court, of the pool of Betheſda; but his moſt celebrated works are the ſacriſty of S. Paulo Maggiore, and the Laſt Supper, in the refectory of the conventuali at Aſſiſi. Solimene poſſeſſed a vivid invention, and conſequently a ready pencil; ſo much ſo, that his execution is always ſpirited and maſterly, equally adapted to almoſt all kinds of ſubjects; and his colouring unites brilliancy and force. He died at Naples in 1747, aged 90.

SOLINGEN, in *Geography*, a town of the duchy of Berg, on the Wipper; 12 miles E.S.E. of Duſſeldorf. N. lat. 51° 8′. E. long. 7° 2′.

SOLINUS, Caius Julius, in *Biography*, a Latin grammarian, but of what particular period is not known, though he is generally referred to the third century. He appears to have reſided chiefly at Rome, but is known only as the author of a work, which he firſt entitled "Collectanea Rerum Memorabilium," afterwards "Polyhiſtor." This is a collection of the remarkable things in different countries, partly tranſcribed, without acknowledgment, from Pliny's Natural Hiſtory; whence the author has been called the ape of Pliny. The work, however, of Solinus contains ſome things not to be found in Pliny, and it contains likewiſe an elucidation of ſome difficulties in the original; and on theſe accounts it has been deemed worthy of the notice of critics. Salmaſius publiſhed an edition of it in two vols. folio, in which, however, the original is almoſt buried in the learning of the commentator. Solinus was author likewiſe of a poem, entitled "Ponticon," of which only a few verſes remain. There have been many editions of the "Polyhiſtor," which were adapted to the taſte of ages fond of wonders. The beſt modern ones are ſaid to be the octavo of Salmaſius, 2 vols. 1689; and Geſner's, printed at Leipſic in 1777.

SOLIO, in *Geography*, a river of Calabria, which runs into the Mediterranean, N. lat. 39° 40′. E. long. 16° 6′.

SOLIPUGA, or Solifuga, in *Natural Hiſtory*, the name given by the Romans to a ſmall venomous inſect of the ſpider-kind, called by the Greeks *heliocentros;* both words ſignifying an animal which ſtings moſt in the country, and ſeaſons, where the ſun is moſt hot.

Solinus makes this creature peculiar to Sardinia; but this is contrary to all the accounts given us by the ancients. It is common in Africa, and ſome parts of Europe.

Almoſt all the hot countries produce this venomous little creature. It lies under the ſand, to ſeize other inſects as they go by; and if it can meet with any uncovered part of a man, will bite him, and the wound will prove very painful and envenomed. It is ſaid that the bite is abſolutely mortal, but probably this is not true. Solinus writes the word *ſolifuga*, and ſo do many others, erroneouſly deriving the name from its flying from the ſun's rays, and burying itſelf in the ſand.

SOLIS, Antonio de, in *Biography*, a celebrated Spaniſh hiſtorian and poet, was born at Alcala de Henares. While he was very young, and a ſtudent, he wrote a comedy, which was extremely well received. It was followed by others, as well as by poems on different ſubjects, by which he raiſed a very high reputation. He was employed in the ſecretary of ſtate's office, and the king, Philip IV., made him his own private ſecretary. In 1661 the queen nominated him hiſtoriographer for the Indies; and it was in this quality that he compoſed his "Hiſtory of the Conqueſt of Mexico," a work which placed him among the moſt approved of the Spaniſh proſe writers, and was greatly applauded both at home and abroad. De Solis took prieſts' orders when he was in the 57th year of his age, after which he renounced all connection with the theatre, and adopted a regularity of life conformable to his character as a prieſt. He died in the year 1686. The comedies of De Solis, which were printed collectively in 4to. Madrid, in 1661, are ſaid by critics to be perplexed in their ſtory, and rather romantic than comic; but they have afforded the foundation of many French plays. His poems are ſaid to diſplay more imagination than correct taſte. His hiſtory is written with ſpirit and elegance, but there are occaſional diſplays of the bombaſt and falſe taſte, and frequently are to be met with great deviations from the truth. The object of De Solis is to make a perfect hero of Cortes, and on this account the hiſtory terminates with the conqueſt of Mexico, and does not touch upon ſubſequent cruelties. It has been tranſlated into the French and Engliſh languages.

Solis, *Aquæ*, in *Ancient Geography*, a town of Albion, in the 14th route of Antonine's Itinerary, between Iſca or Caerleon and Calleva or Silcheſter. Aquæ Solis was unqueſtionably Bath, which was much frequented by the Romans for its warm and medicinal ſprings.

Solis *Via*. See Via.

SOLISTEN, in *Geography*, a town of Sweden, in the province of Angermanland; 42 miles N.W. of Hernoſand.

SOLITAIRE Island, a ſmall iſland in the South Pacific ocean; 25 miles S. of Kerguelen's land. S. lat. 49° 49′. E. long. 68° 6′.

SOLITARIÆ Glandulæ, in *Anatomy*, thoſe mucous glands of the inteſtines, which are arranged ſingly. See Intestine.

SOLITARY, Solitarius, ſomething retired, or in private; remote from the company or commerce of others of the ſame ſpecies. See Hermit.

Solitaries, a denomination of the nuns of St. Peter of Alcantara, inſtituted in 1676, by cardinal Barberini, when abbot of Notre Dame de Farſa, in that city.

The deſign of their inſtitute is to imitate the ſevere, penitent life of St. Peter of Alcantara; to keep a continual ſilence; never open their mouths to any body but themſelves; employ their time wholly in ſpiritual exerciſes; and leave the temporal concerns to a number of maids, who have a particular ſuperior in a ſeparate part of the monaſtery. They always go bare-footed, without ſandals, gird themſelves with a thick cord, and wear no linen.

Solitary *Column*, is a column that ſtands alone in any public place; as the Trajan column.

Solitary *Worm*, *Solium tænia*, or *Lumbricus latus*, is a worm ſometimes found in the inteſtines, and which is always the only one of the kind there; as commencing from the pylorus, and extending thence the whole length of the inteſtines; ſo that there is no room for another. See Tænia and Worm.

Solitary *Iſland*, in *Geography*, an iſland in the South Pacific ocean, diſcovered by Mendana in the year 1595. It is low, round, and planted with trees; and the coaſt is ſurrounded with rocks. S. lat. 10° 4′. W. long. 178° 20′.

Solitary *Iſlands*, a cluſter of ſmall iſlands near the eaſt coaſt of New Holland. S. lat. 30° 8′.

SOLITAURILIA, in *Antiquity*. See Suovetaurilia.

SOLIVA, in *Botany*, a genus in the *Flora Peruviana*, page 102, dedicated to Salvator Soliva, a Spaniſh phyſician and botaniſt. *De Theis*.

SOLIVE, Fr., among *Carpenters*, a joiſt, rafter, or piece of wood, either ſlit or ſawed, with which the builders lay their cielings.

SOLJURA, in *Geography*, a town of Bengal; 28 miles S.S.E. of Curruckpour.

SOLKIEV, or Zolkiev, a town of Auſtrian Poland, in Galicia; 10 miles N. of Lemberg.

SOLLAM Moss. See Solway *Moſs*.

SOLLAPOUR, a circar of Hindooſtan, in Viſiapour, between the rivers Kiſtnah and Beema, near their junction.—Alſo, a town of Hindooſtan, and capital of the forementioned circar, on the Kiſtnah; 120 miles S.E. of Viſiapour. N. lat. 16° 22′. E. long. 77° 10′.

SOLLECITO, in *Italian Muſic*. This word has two acceptations: the one implies that a movement is to be performed with a mournful and ſorrowing expreſſion; the other means carefully, and with accuracy.

SOLLERGUNGE, in *Geography*, a town of Hindooſtan, in Oude; 9 miles E. of Lucknow.

SOLLERO, a town of Sweden, in Dalecarlia, on an iſland in lake Siljan; 48 miles N.W. of Fahlun.

SOLLIES LE PONT, a town of France, in the department of the Var; 13 miles S. of Brignole.

SOLMISATION, or naming the notes in the ſcale according to the hexachord of Guido. See Mutations and Serra.

Solmisation *of the Greeks*. The ancient Greeks had their ſolmiſation in vocal muſic, as well as the moderns; having for that purpoſe uſed four monoſyllables, ending with different vowels, for the exerciſe of the voice in ſinging; like our *mi*, *fa*, *ſol*, *la*. Theſe were, for the firſt note of each tetrachord, τᾶ; for the ſecond, τῆ; for the third, τῶ; and for the fourth, if it did not ſerve as the firſt of the adjoining and relative tetrachord, τε̃; but if it began a new tetrachord, it was called by the firſt name, τᾶ.

The repetition of theſe monoſyllables is a further proof that the *fourth*, in the ancient muſic, ſerved as a boundary to a ſyſtem of four ſounds, in the ſame manner as a hexachord did in the Guido ſcale, and as an octave does for eight ſounds in the more modern practice.

SOLMIZARE, in the *Italian Muſic*. See Solfeggiare.

SOLMS, in *Geography*, a principality of Germany, ſituated in the Wetterau. The counts of Solms are ſuppoſed to be deſcended from the houſe of Naſſau, and are divided into ſeveral branches, *viz*. Solms Braunfels, Solms Hohen-Solms, Solms Laubach, Solms Rodelheim, and Solms Lich.

Solms, *Hohen*. See Hohen-solms.

Solms, or *Burg Solms*, a town of Germany, in the principality of Solms Braunfels, having formerly a caſtle, which gave name to the county; 1 mile E. of Braunfels.

SOLMSBACH, a river of Germany, which runs into the Lahn, 2 miles N.E. of Braunfels.

SOLNAN, a river of France, which joins the Seille at Louhans, in the department of the Saone and Loire.

SOLNIZ, a town of Bohemia, in the circle of Koniggingratz; 15 miles E. of Konigingratz.

SOLO, a mountain of Naples, in Lavora; 10 miles S.W. of Ponte Corvo.—Alſo, a town of Hindooſtan, in Mewah; 30 miles N. of Dig.—Alſo, a town of South America, in the province of Cordova; 100 miles N.W. of Cordova.

Solo, in *Italian Muſic*, uſed ſubſtantively, implies a compoſition for a ſingle inſtrument, with a quiet and ſubdued accompaniment, to diſplay the talents of a great performer; as a ſolo for a violin, German flute, or violoncello. In full pieces, *concertate*, each part is informed when it becomes principal, by the word *ſolo;* and when ſubordinate, by *tutti*, which implies the chorus, or full band.

In the concertos of Corelli, Geminiani, and Handel, chiefly compoſed *à due cori*, or two orcheſtras, the principal parts are ſaid to belong to the *concertini*, or ſolo parts; as *violino primo concertino*, *violino ſecondo del concertino*, &c.: and the inferior parts, that only play in the full chorus, are called *ripieni;* as *violino primo ripieno*, *violino ſecondo ripieno*, or *del concerto groſſo*, or the great and full concert.

Solos, which uſed to afford the moſt exquiſite delight to perſons of refined taſte, when compoſed and performed by great maſters, are now wholly laid aſide; and whoever attempts to perform one, is ſubjected to a penalty inſtead of a reward; a law inſtituted at the concert of ancient muſic, where a compoſition was never thought complete by the late earl of Sandwich, without a kettle-drum, nor with, unleſs he beat it himſelf. And at the Commemoration of Handel, the double drums, double cartels, tromboni, &c. augmented his lordſhip's pleaſure, in proportion to the din and ſtenterophonic ſcreams of theſe truly ſavage inſtruments; which, in ſo wide a building as Weſtminſter Abbey, and ſoftened by ſo powerful a chorus of voices and inſtruments as were aſſembled at the Commemoration, had, occaſionally, a fine effect; but in a more confined ſpace, the almoſt inceſſant uſe of the tromboni, and perpetual roll of the double drums, annihilate all the pleaſing effects of mellifluous tones.

SOLOAYS, in *Geography*, a town of Pennſylvania; 24 miles N. of Eaſton.

SOLOE, in *Ancient Geography*, a town of the iſland of Cyprus, built, according to Strabo, by Acamas and Phalerus, both Athenians, but, as Plutarch ſays, by Demophon, on the banks of the river Clarius. It was ſituated on an eminence in a barren territory, and called "Æpira," denoting *high*, on account of its elevated poſition. Many ages afterwards, when Solon came to Cyprus and formed a league of friendſhip with Phylocyptus, one of the kings of the iſland, he adviſed him to remove the town to a neighbouring plain, on the banks of a river with a port over-againſt Cilicia. This new city was called Σολοι, and in Latin Solæ or Soli, from the name of Solon. It is now "Solin." Another town of the ſame name in Cilicia, is called by Pliny "Soloe Cilicii," by way of diſtinction from the other. This was afterwards called "Pompeiopolis."

Soloe, a cape of Africa, on the Atlantic ocean, which the Periplus of Hannon places at the diſtance of three days' journey ſouth of the promontory "Hermeum." Hannon built on the ſummit an altar conſecrated to Neptune, and it was in proceſs of time adorned with bas-relief works of art, which rendered it the moſt celebrated place on the coaſt.

SOLOEIS, a promontory of Libya, at the extremity of mount Atlas, now called Cape Cantin. It is mentioned by Herodotus.

SOLOENTIA, a promontory of interior Libya, between the mouth of the river Nunius and that of the river Malla, according to Ptolemy.

SOLOFRA, in *Geography*, a town of Naples, in Principato Ultra; 18 miles S. of Benevento.

SOLOGNE, a diſtrict of the government of Orleannois, in France, before the revolution, about 60 miles in length, and 18 in breadth, of which Romorantin was the capital.

SOLOK, a town of Lithuania, in the palatinate of Troki, on a lake; 40 miles N.N.E. of Zytomiers.

SOLOMBO, GREAT, a ſmall iſland in the Eaſt Indian ſea. S. lat. 5° 36′. E. long. 114° 45′.

SOLOMBO, *Little*, a ſmall iſland, a little N.E. of Great Solombo.

SOLOMBOL, an iſland of Ruſſia, in the government of Archangel, ſituated on the river Dwina; which has a dock-yard for building ſhips, with a fort and garriſon; 5 verſts above Archangel.

SOLOMIAC, a town of France, in the department of the Gers; 14 miles S.E. of Lectoure.

SOLOMON, in *Biography*, a king of the Jews, eminently diſtinguiſhed by his wiſdom, wealth, and extent of territory, was the ſon of David by Bathſheba, formerly the wife of Uriah, and born in the year B.C. 1033. By the influence of Bathſheba, and the recommendation of Nathan, Zadok, and other friends, who thought it neceſſary to counteract the views and meaſures of Adonijah, David's eldeſt ſon, he was proclaimed the deſtined ſucceſſor of his father before his death. When this event took place, B.C. 1015, he aſcended the throne of all Iſrael, not only without oppoſition, but amidſt the acclamations of the people. For his greater ſecurity, he ordered Adonijah, and Joab, who was attached to his intereſt, to be put to death. As ſoon as he was confirmed in his kingdom, he contracted an alliance with Pharaoh, king of Egypt, and married his daughter, whom he brought to Jeruſalem, and for whom he afterwards built a ſumptuous palace; receiving for her dowry the city of Gezer, which had been taken from the Canaanites. It was on occaſion of this marriage, as ſome have thought, that he compoſed the Canticles, as a kind of epithalamium; and the 45th Pſalm has been alſo referred to the ſame event. About this time he led his troops, and all Iſrael, to Gibeon, where he offered a thouſand burnt-offerings upon the brazen altar. In the following night he is ſaid to have been favoured with a viſion, in which God promiſed to grant him whatſoever he deſired: and as the object of his prayer was wiſdom for diſcharging the duties of his high office, his requeſt was fully granted. Upon his return to Jeruſalem, he offered a great number of ſacrifices on the altar, before the ark of the Lord, and made a great feaſt for his ſervants. As an inſtance of his wiſdom, he decided a diſpute between two mothers, who claimed the ſame child. (1 Kings, iii. 16—28.) In token of the acceptableneſs of his petition, he alſo obtained, more than he aſked for, a gratuitous donation, on the part of God, of riches and honour: which were amply diſplayed in the magnificence of his court, the amount of his revenues, the multitude of his ſubjects, the number of his civil and military eſtabliſhments, and a variety of other circumſtances, which rendered him one of the moſt celebrated monarchs of the Eaſt. His reign was peaceful and proſperous. Judah and Iſrael were united and ſecure, and his neighbours either formed an alliance with him, or paid him tribute. His dominions extended from the Euphrates to the Nile; and his reputation for wiſdom was ſpread through all nations.

As ſoon as Hiram, king of Tyre, heard of his acceſſion to the throne of Iſrael, he deputed ambaſſadors to congratulate him; and with the acknowledgment of this meſſage, he requeſted to be ſupplied with wood, and able artificers to aſſiſt in conſtructing the temple at Jeruſalem, which, in deference to his father's vow, he had undertaken to execute. The completion of this magnificent edifice conferred ſingular celebrity on the reign of Solomon. It was begun in the 4th year of his reign, and the ſecond after the death of David, B.C. 1012, and 480 years after the Exodus. In the various departments of this great work, he employed no leſs than 183,600 perſons. This wonderful ſtructure was completed in the 11th year of Solomon, or in the ſhort ſpace of ſeven years; and it was ſolemnly dedicated on Friday, Oct. 30, B.C. 1000 years. Solomon afterwards built two palaces, one for himſelf and another for his queen; and the conſtruction of the temple and palaces occupied a period of twenty years. He alſo built the walls of Jeruſalem; and he repaired and fortified a great number of cities. The great expence which he thus incurred was defrayed by a commerce which he carried on from Ezion-geber and Eloth, on the Red ſea, to Ophir; for the ſituation of which ſee OPHIR.

Solomon, however, notwithſtanding the wiſdom which rendered him ſo famous, had not ſufficient fortitude for reſiſting the temptations that accompanied his proſperity. He was betrayed, in the moſt culpable and diſgraceful manner, into the vices attendant on luxury and ſenſuality. Beſides 700 wives, he had 300 concubines; and in his declining age, though he had erected a temple to Jehovah the true God, and was thus implicitly pledged to preſerve the religion of the Jews pure and uncorrupted, their influence cauſed him to degenerate into the moſt inexcuſable idolatry, ſetting up as objects of worſhip, Aſhtoreth, goddeſs of the Sidonians, Moloch, the idol of the Ammonites, and Chemoſh, the god of the Moabites, and building for them temples on the mount of Olives, over-againſt, and eaſt, of Jeruſalem. As a juſt puniſhment of his culpable conduct, the ſovereigns of Edom and Syria were excited againſt him, and he ſaw, before his death, the commencement of that revolt which terminated in the diviſion of the kingdom.

Solomon cloſed his life and reign in the year B.C. 975, having reigned 40 years, at the age of 58. Such is the Scripture account, but Joſephus aſſigns to him a reign of 80 years, and a life of 94 years. He was buried in the city of David, and ſucceeded by his ſon Rehoboam, who reigned only over part of the divided kingdom of Iſrael. Tradition aſcribes to him a great number of books; but thoſe only under his name admitted into the canon of Scriptures, are the "Proverbs," "Eccleſiaſtes," and the "Canticles." See each in its proper place.

SOLOMON'S *Seal*, in *Botany*, a plant called by authors *polygonatum*; which ſee. See alſo CONVALLARIA.

SOLOMON'S *Iſlands*, in *Geography*, a group of iſlands in the Pacific ocean, diſcovered by Mendana in 1565; and afterwards by M. Surville, in 1767, who called them Arſacides, or Aſſaſſins; they were paſſed by Lieut. Shortland in 1788, and called by him New Georgia. See ARSACIDÆ and GEORGIA.

SOLON, in *Biography*, one of the ſages of Greece, and the celebrated law-giver of the Athenians, was born in the ſeventh century before Chriſt. He was of a family deſcended from the ancient kings of Athens, but which, in the revolutions of time, had fallen into indigence, for he paſſed his early years in travelling on mercantile buſineſs. He ſhewed an early diſpoſition for poetry, which he firſt exerciſed on the following occaſion. The Athenians, in a war with the Megarenſians, had been expelled from the iſle of Salamis, and their efforts to recover it were attended with ſo much loſs, that a law paſſed to make it a capital offence for any one to propoſe a renewal of the attempt. Solon, feeling mortified at the diſgrace attached to this decree, compoſed an elegy adapted to rouſe the ſpirits of the people, and feigning himſelf to be under the influence of a temporary inſanity, ran into the market-place, mounted the cryer's ſtool, and pronounced his verſes with great vehemence. The crowd gathered round felt a riſing ardour; which was farther excited by an harangue of Piſiſtratus, and they, without heſitation, decreed a war againſt the Megarenſians. Salamis was recovered, and, according to a tradition which has been generally received, by a ſtratagem of Solon's. He afterwards increaſed his reputation by adviſing a war with the people of Cirrha, who had ravaged the ſacred territory of Delphi, and contributed to the reduction of their city. Athens at this time was in a very unquiet ſtate, ariſing as well from the contentions of different political factions, as from the oppreſſions of the ſuperior claſſes, who had reduced a great part of the common people to ſlavery, in conſequence of their debts. Solon, in this emergency, was looked up to by the citizens in general as the man who, by his wiſdom and virtue, was beſt qualified to reſtore public tranquillity, and a large party was deſirous of raiſing him to the ſovereignty. This, however, he poſitively declined; but being choſen archon by acclamation in the year B.C. 594, he ſet himſelf to compoſe the diſſentions by moderate meaſures. At firſt his plans were not well received, but reflection convinced all parties that his object was good, and they unanimouſly inveſted him with the high truſt of new-modelling their laws and conſtitution. He abrogated the ſanguinary laws of Draco, excepting ſuch as related to homicide. Democracy being the form of government to which the Athenians were attached, he regarded it as the baſe of his new conſtitution, but ſtudied to give it due checks and counterbalances. Hence he divided the citizens into four claſſes, three of which were formed upon different ſcales of property: the fourth included thoſe of the loweſt order, who were deſtitute of all property. Theſe were excluded from public offices, but admitted to vote in the general aſſembly of the people. As this body was in poſſeſſion of the ſupreme power, and judged cauſes in the laſt reſort, the conſequence, or at leaſt the ſafety, of the meaneſt members of the ſtate was ſufficiently ſecured. To prevent inconſiderate reſolutions in the democratic aſſembly, he inſtituted a ſenate of 400, which was to have a prior deliberation upon every propoſal to be ſubmitted to the general aſſembly. Solon revived the ancient Areopagus, and ordained that it ſhould be compoſed only of thoſe who had paſſed through the office of archon, the higheſt magiſtracy of the ſtate; which conferred on it a ſplendour that rendered its decrees revered through the whole of Greece. The laws of Solon have been ranged under various heads, but it would not comport with our plan to enter at large into their nature. Their general ſpirit is mild and equitable. One of them has been the ſubject of much political diſcuſſion: this was, that in any caſe of civil conteſt, in which oppoſite parties take up arms, the citizen who remains neuter ſhall be puniſhed with exile and confiſcation of goods: another regulation, very ſalutary in its effects, and well adapted to a ſmall ſtate, was, that the Areopagus ſhould have full power to enquire how every citizen ſupported himſelf, with the view of inflicting penalties on the idle.

As an apology for any imperfection that might be found in his code, Solon was accuſtomed to ſay, "I have given to the Athenians not the beſt poſſible laws, but the beſt they were capable of receiving." The code given by Solon was intended by the author to be in force a century, and then to be reviſed and amended, as occaſion might ſeem to demand. After the promulgation of his code, Solon was continually moleſted by perſons who came to him, either for explanation of obſcure paſſages, or with propoſals for improvements of which they imagined it capable. To avoid their importunities he reſolved to travel; and having obtained leave of abſence for ten years, and exacted an oath from the citizens, that nothing ſhould be altered till his return, he ſailed to Egypt. He there procured inſtructions in philoſophy from the prieſts of Heliopolis and Sais, one of whom, it is ſaid, in the pride of Egyptian antiquity, ſaid to him, "Solon, Solon, you Greeks are children, you have not a grey-headed man among you." From Egypt he went to Cyprus, where he ſuggeſted to one of the petty princes the erection of a new city, which was called after his name. About this time alſo he held a conference with Thales, the Mileſian, recorded by Plutarch, and it was about this period that he viſited the court of Crœſus, king of Lydia.

On his return to Athens, he found the ſtate in great confuſion from the conteſts of different factions. Piſiſtratus had placed himſelf at the head of the popular party, and was aiming, through its favour, at the ſovereignty. Solon attempted to oppoſe the current, but in vain: he appeared with his arms in the aſſembly, and harangued the people, but he had loſt his influence, and being wholly unable to rouſe the people, he withdrew from Athens never more to return. The place and time of his death have never been accurately aſcertained, but it is generally believed that he died at Cyprus, at the age of eighty. The Athenians held his memory in ſuch high reverence, that they erected a ſtatue of braſs to his memory in the forum: the opinion of mankind at large has, however, ſurvived the brazen memorial, and he is ſtill regarded as among the greateſt benefactors of mankind.

Solon was one of thoſe early Greek philoſophers who were diſtinguiſhed by the appellation of the ſeven wiſe men. Philoſophy had in that age attained to no ſyſtematic cultivation, and the only monuments of the wiſdom of moſt of thoſe ancient ſages which have come down to us, are ſome ſhort moral and prudential maxims, which ſeem to require for their diſcovery little depth of penetration or extent of obſervation. They have, however, been conſecrated to perpetual remembrance by the gratitude and admiration of Greece. That the laws of Solon might be open to the inſpection of the people, they were inſcribed on wooden tablets, turning on axes, and ſaid to have been of different forms, according as the laws which they contained related to private or public affairs. The mode of writing is that which is termed in the Greek language βουστροφηδον, that is, from the right to the left, and then from left to right; the term is taken from the method uſed in ploughing, which was always done in ancient times by means of oxen. The fragments of Solon's laws have been collected by various writers, but with very great care by Samuel Petit, in a learned work, which is, however, not free from inaccuracies, and conjectures that will not bear the teſt of criticiſm. This work was publiſhed at Paris, in folio, in the year 1635, under the title of "Leges Atticæ." It was republiſhed by Weſſeling, with many improvements, and the additions of his own remarks and thoſe of other critics, in 1742. Diogenes Laertius has annexed to his life of Solon four epiſtles, which he aſcribes to that philoſopher, addreſſed to Periander, Epimenides, Piſiſtratus, and Crœſus. Of his ſayings or maxims, the following have come down to us. "Laws are like cobwebs, that entangle the weak, but are broken through by the ſtrong:" "He who has learned to obey, will know how to command:" "In every thing you do, conſider the object and end:" "In all things let reaſon be your guide:" "Diligently contemplate excellent things." Of the poetical talents of Solon, time has left us little opportunity of judging. Thirty-one fragments, collected from Stobæus and other writers, have been printed by Brunk. They are written in various meaſures, but chiefly in the elegiac. Many of them, in a ſtyle reſembling that of Theognis, the poet of Megara, are employed in the illuſtration of uſeful maxims relative to the conduct of life and formation of manners. The ſcanty fragments of the Salaminian elegy, to which we have already referred, manifeſt conſiderable animation, ſo that we can eaſily give credit to what is ſaid of the effect which it produced.

Solon, in *Geography*, a military townſhip of America, in the ſtate of New York and county of Cortland, bounded N. by Troxton, E. by Chenango county, S. by Cincinnatus, and W. by Homer; 10 miles E. of Homer, and 132 miles W. of Albany. It is 12 miles ſquare, and an excellent tract of land. The timber in this townſhip is maple, beech, elm, aſh, butternut, baſs, together with ſome pine and hemlock. The ſoil is principally a warm gravelly loam, well adapted for farming, and the inhabitants are farmers. The population in 1810 conſiſted of 1270 perſons. The roads in this townſhip are in good order; and great numbers of lean cattle are driven from hence every year to Philadelphia, Weſt Cheſter and Ducheſs counties.—Alſo, a town of Maine, in the county of Somerſet, containing 312 inhabitants.

SOLONIUM, in *Ancient Geography*, a town of Italy, in Etruria, according to Dionyſius Halicarnaſſus.

SOLOOKUPA, in *Geography*, a town of Bengal; 15 miles N.N.E. of Nuldingah.

SOLOON, a ſmall iſland in the Eaſt Indian ſea; 25 miles from Samar. N. lat. 10° 55′. E. long. 125° 42′.

SOLOR, an iſland in the Eaſt Indian ſea, S. of Celebes, about 70 miles in circuit, ſeparated from the E. coaſt of the iſland of Flores by a narrow channel, called the Straits of Flores. S. lat. 8° 33′. E. long. 125° 42′.

SOLOS, Σολος, in *Antiquity*, an inſtrument with which the exerciſe of the quoit was performed, which ſome will have to be diſtinguiſhed from the diſcus, becauſe that was of iron, this of ſtone; but others, with more reaſon, report that the difference conſiſted in this, *viz.* that the σολος was of a ſpherical figure, and the diſcus broad.

SOLOT, in *Geography*, a ſmall iſland in the Indian ſea, near the coaſt of Africa. S. lat. 12° 8′.

SOLOTHURN. See Soleure.

SOLOTKOVA, a town of Ruſſia, in the government of Irkutſk, on the Ilmin; 60 miles S.W of Orlenga.

SOLOTNICK, in *Commerce*, a weight in Ruſſia, which expreſſes the fineneſs both of gold and ſilver; the pound or other weight being divided into 96 ſuch parts: ſo that the ſolotnick is alſo the $\frac{1}{96}$th part of a Ruſſian pound weight. According to the mint regulations eſtabliſhed in the reign of the emperor Paul, and confirmed by an edict of the emperor Alexander, in 1801, $22\frac{3}{4}$ rubles are to contain a Ruſſian pound of fine ſilver; and they are to be $83\frac{1}{5}$ ſolotnicks (or 10 oz. 8 dwts.) fine; ſo that each ruble ſhould weigh $320\frac{1}{4}$ Engliſh grains, and contain $277\frac{1}{2}$ grains of fine ſilver. It was declared that no gold coin ſhould be hereafter ſtruck in Ruſſia, except the imperial and half-imperial, the ſtandard of which was raiſed to $94\frac{1}{2}$ ſolotnicks, or $188\frac{1}{4}$ Engliſh grains. Accordingly,

	£	s.	d.	
The imperial is worth	1	12	$9\frac{1}{2}$	valued in Engliſh gold.
The ducat	0	9	1	
The ruble of 1763	0	3	3	valued in Engliſh ſilver.
——— of 1801	0	3	$2\frac{1}{2}$	

By an aſſay lately made on a number of rubles at the London Mint, by order of the Bank of England:—

Rubles of 1763, weight from 14 dwts. 21 grs. to 15 dwts. 20 grs.; average 15 dwts. $8\frac{1}{2}$ grs.; fineneſs 44 dwts. worſe than Engliſh, that is, 8 oz. 18 dwts.

Rubles of 1801, weight from 13 dwts. 2 grs. to 13 dwts. 12 grs.; average 13 dwts. 7 grs.; fineneſs 14 dwts. worſe than Engliſh, that is, 10 oz. 8 dwts. Thus we have the value of the old ruble 3*s.* 2*d.* ſterling, and of the new, 3*s.* $2\frac{1}{2}$*d.*

The Ruſſian weights are as follow, *viz.* the berquet or berkowitz contains 10 poods; the pood, 40 lbs.; the pound, 32 loths; and the loth, 3 ſolotnicks. The Ruſſian pound weighs 28 loths, Cologne weight, or 6314 troy grains. Hence 500 lbs. Ruſſian = 451 lbs. avoirdupois. The ordinary computation among merchants is, that 36 lbs. avoirdupois = the pood of 40 lbs. Ruſſian; and that 63 poods = 1 ton avoirdupois. Kelly's Cambiſt.

SOLOVETZKOI, in *Geography*, a ſmall iſland of Ruſſia, in the White ſea. N. lat. 64° 55′. E. long. 30° 14′.

SOLRE-LIBRE (*Le Chateau*), a town of France, in the department of the North, and chief place of a canton, in the diſtrict of Aveſnes; 6 miles N.E. of Aveſnes. The place contains 1525, and the canton 7134 inhabitants, on a territory of $212\frac{1}{2}$ kiliometres, in 23 communes.

SOLSEQUIUM, a word uſed by ſome chemical writers as a name for ſulphur.

SOLSOGAN Bay, in *Geography*, a bay on the S. coaſt of the iſland of Luçon. N. lat. 13° 12′. E. long. 123° 50′.

SOLSONA, or Salsona, a town of Spain, in Catalonia, the ſee of a biſhop, ſuffragan of Tarragona; 97 miles E. of Saragoſſa. N. lat. 42° 2′. E. long. 1° 22′.

SOLSTICE, Solstitium, in *Aſtronomy*, the time when the ſun is in one of the ſolſtitial points; that is, when he is at his greateſt diſtance from the equator, which is 23° 28′: thus called, becauſe he then appears to *ſtand ſtill*, and not to change his place in the degrees of the zodiac, any way: an appearance owing to the obliquity of our ſphere, and to which thoſe who live under the equator are ſtrangers.

The ſolſtices are two in each year; the *æſtival* or *ſummer* ſolſtice, and the *hyemal* or *winter* ſolſtice.

The ſummer ſolſtice is when the ſun is in the tropic of Cancer; which is on the 21ſt of June; when he makes the longeſt day.

The winter ſolſtice is when he enters the firſt degree of Capricorn; which is on the 22d of December; when he begins to return towards us, and makes the ſhorteſt day.

This is to be underſtood as in our northern hemiſphere; for in the ſouthern, the ſun's entrance into Capricorn makes the ſummer ſolſtice, and that into Cancer the winter ſolſtice.

Mr. Pond, the aſtronomer royal, from obſervations made on the ſummer and winter ſolſtice, deduces the mean obliquity of the ecliptic for January 1, 1813, as 23° 27′ 51″.50 from the former, and from the latter 23° 27′ 47″.35.

SOLSTITIAL Points, are thoſe points of the ecliptic, by which the ſun's aſcent above the equator, and his deſcent below it, are terminated.

The firſt point, which is in the beginning of the firſt degree of Cancer, is called the *æſtival* or *ſummer* point; and the latter, which is in the beginning of the firſt point of Capricorn, the *winter* point. The ſolſtitial points are diametrically oppoſite to each other.

SOLSTITIAL *Colure*, is that which paſſes through the ſolſtitial points. See COLURE.

SOLTAU, in *Geography*, a town of Weſtphalia, in the principality of Luneburg Zelle. The inhabitants are for the moſt part clothiers; 29 miles N.N.W. of Zell. N. lat. 53° 4′. E. long. 9° 55′.

SOLTCAMP, a town of Holland; 13 miles N.W. of Groningen.

SOLTE, a river of Germany, which runs near Kloppenburg in Munſter, and joining the Vehne, takes the name of Soeſt, on the borders of Frieſland.

SOLTENHAGEN, a town of Hinder Pomerania; 8 miles E. of Zachan.

SOLTKOTT, a town of Weſtphalia, in the biſhopric of Paderborn, famous for its ſalt-works; 6 miles S.W. of Paderborn.

SOLTZ, a town of Germany, in the county of Henneberg; 4 miles N.W. of Meinungen.

SOLVA, a river of South Wales, in the county of Pembroke, northward of Milford Haven, which forms the port and harbour of the little town of the ſame name. This ſmall town is ſituated in a deep valley, pervaded by the above-mentioned river. Moſt of the houſes are of modern erection, and exhibit a neat appearance. They lie principally on the weſtern ſide of the vale, forming one ſtreet in the direction of the river, but ſcattered without plan or order on the ſteep acclivity above. Solva is a ſea-port, and carries on a ſmall commercial intercourſe with the adjacent parts of the coaſt, chiefly with Milford. Its rapid increaſe in ſize, of late years, is an evidence of its proſperity.

SOLVACH BAY, a creek of South Wales, on the N. ſide of St. Bride's bay; 3 miles E. of St. David's.

SOLUBILITY *of Salts*, in *Chemiſtry*, denotes their capacity to unite with, and remain ſuſpended in water; and the different ſalts poſſeſs different degrees of ſolubility, requiring more or leſs of this fluid for their ſolution. See SALTS.

SOLUBLE, in *Medicine*, looſe, or apt to go to ſtool. In chemiſtry it ſignifies eaſily diſſolvable.

SOLUBLE *Tartar*. See TARTAR, and *Tartrate of Potaſh*, under SALTS.

SOLUBLE *Matter of Plants*, in *Agriculture*, the ſoluble parts of them, or the portion of vegetable matter which they contain, and which is capable of ſolution and of being employed as the food and nouriſhment of man and animals. The quantities or proportions of this matter, which different plants or vegetable ſubſtances poſſeſs, is very different. It is conſequently not improbable, but that the difference in the nutrient powers of different plants and ſubſtances of the vegetable kind may, in a great meaſure, depend upon this difference in the quantities or relative proportions of the ſoluble matter which they may contain, but their utility and importance as food do not appear to be wholly dependent upon this circumſtance.

SOLUBLE *Matter of Soils*, the reſolvable matter in them, or the quantity and proportion of this ſort of matter which they contain in different caſes, and which is capable of being converted to uſe as food for the ſupport and growth of plants as crops. Some ſoils abound much with materials of this nature, while others are almoſt wholly deficient of them. This, in ſome degree, conſtitutes the difference of fertility in lands, though it is influenced by a great variety of other cauſes. See SOIL.

The rich black ſoils are, for the moſt part, the moſt abundantly provided with this kind of matter, though many others poſſeſs it in a conſiderable proportion.

SOLUE, in *Geography*, a town of Africa, in the country of Barca; 10 miles S.W. of Curen.

SOLVENT, the ſame with *diſſolvent*. See SOLUTION.

SOLVENT, *Univerſal*, in *Alchemy*. See ALKAHEST.

SOLVESBORG, in *Geography*. See SOLFWITZBURG.

SOLUMBERE, a town of Hindooſtan, in the circar of Oudipour; 35 miles S. of Aſawully.

SOLUMBERGA, a town of Italy, in Friuli; 7 miles N. of Aviano.

SOLUS, in *Ancient Geography*, a town of Sicily, according to Pliny; marked in the Itinerary of Antonine as the route from the Lilybæan promontory to the Tyndaris, between Panormus and Thermæ.—Alſo, a promontory of Libya, on the coaſt of the Atlantic ſea, according to the Periplus of Scylax. A temple, dedicated to Vengeance and Neptune, was erected on the ſummit of this promontory.

SOLUSAPRA, a town of Sicily, on the route from Tyndaris to the Lilybæan promontory, according to the Itinerary of Antonine.

SOLUTIO CONTINUI, or *Solution of Continuity*, a term uſed by phyſicians, &c. to expreſs a diſorder common to the ſolid parts of the body, in which their natural coheſion is ſeparated: as by a wound, or other cauſe.

If this happen to a ſimple, ſimilar part of the body, it is called ſimply *ſolutio continui:* if to a compound or organical part, it acquires a particular denomination, from the nature of the part, the difference of the cauſe, or the manner of application; as a *wound, rupture, fracture, puncture, fiſſure, contuſion, ulcer, corroſion, dilaceration, exfoliation, caries*, &c.

SOLUTION, SOLUTIO, in *Algebra* and *Geometry*, is the anſwering of a queſtion; or reſolving any problem propoſed. See RESOLUTION and REDUCTION *of Equations*.

The ſolution of the problem of the quadrature of the circle, and that of the duplicature of the cube, by right lines, are held impoſſible.

SOLUTION *of Continuity*, in *Surgery*. See SOLUTIO *Continui*.

SOLUTION, in *Phyſics*, the reduction of a ſolid or firm body into a fluid ſtate, by means of ſome menſtruum.

Solution is frequently confounded with what we otherwiſe call *diſſolution*, but there is a difference.

SOLUTION, in *Chemiſtry*, is ſometimes uſed for the analyſis, or reduction, of a natural body into its chemical principles.

In this ſenſe, ſolution is the ſame with what we otherwiſe call reſolution.

Solution, as the term is commonly uſed by chemical writers, conſiſts in an union formed by the integrant parts of one body with thoſe of another body of a different nature; and this cannot be effected till the aggregation of one, at leaſt, of the two bodies is broken. And as bodies, whoſe aggregation is broken, are neceſſarily in a ſtate of fluidity, or of vapours, an axiom has been formed, *corpora non agunt niſi ſint fluida, i. e.* bodies do not act unleſs they be fluid.

The two bodies which unite in ſolution, are commonly diſtinguiſhed by two different names. That body is generally called the *ſolvent*, which, by its fluidity or acrimony, appears to be active; and the body which, from its want of taſte, or from its ſolidity, appears to be altogether paſſive, is ſaid to be *diſſolved. E. g.* When metal or marble is diſſolved in aqua fortis, the ſolid bodies are conſidered as being diſſolved, and aqua fortis as the ſolvent. Nevertheleſs, it muſt be remembered, that two bodies, which unite together in ſolution, act reciprocally upon one another, and their union is the effect of their mutual affinity or tendency to each other: and thus the marble and metal act as much upon the nitrous acid as this does upon them.

That a ſolid may be diſſolved in a fluid, it is neceſſary that the force of affinity between the two ſhould be ſufficient to overcome the force of coheſion between the particles of the ſolid; and hence it is, that heat ſo much aſſiſts ſolution by leſſening the force of coheſion between all particles of matter.

M. Gellert, however, repreſents as ſolvents, the bodies which are generally conſidered as diſſolved, and hence, he ſays, that ſand diſſolves alkali. If, indeed, we allow the action of the combining bodies to be mutual, it ſignifies little which we call the ſolvent, and which the body diſſolved; though it ſeems more clear and accurate to call that body the ſolvent, whoſe integrant parts are already ſeparated before the ſolution, and that the body diſſolved, whoſe integrant parts are only diſunited during the act of ſolution. The ſolution of bodies may be effected either by the humid, or by the dry way; of the former kind are thoſe ſolutions, in which the integrant parts of one or both of the two bodies are diſtributed in an aqueous fluid, *e. g.* of acids; and thoſe ſolutions, in which one or both bodies are rendered fluid by fire, as in vitrification, and in alloys of metals with each other, are of the latter kind. A perfect ſolution requires, that each of the integrant parts of one body be united to one of the integrant parts of another: hence, if one of them be tranſparent, we ought to have, after the mutual ſolution, a tranſparent compound, ſuch as occurs in the ſolutions of calcareous ſtones and acids, and thoſe of earths by alkalies: whereas the ſolution of ſoap in water is incomplete; and the ſame may be ſaid of glaſſes that are not perfectly tranſparent.

As the ſolution of two bodies can only be effected by the mutual attraction of their parts to each other, theſe parts, after the ſolution, are found to adhere together: ſo that heavy bodies, *e. g.* corroſive ſublimate, may be ſuſpended in the thinneſt and lighteſt liquids, *e. g.* ſpirit of wine, when they are truly diſſolved by each other.

In all caſes of ſolution at a common temperature, it generally happens, that the mixture in the act of ſolution becomes either warmer or colder than the ingredients were before the mixture. This is owing to an evolution or abſorption of free caloric, from the mixtures having a leſs or greater capacity for caloric, than the mean capacity of the two ſubſtances taken ſeparately. See CALORIC.

It happens alſo, in the greater number of caſes of ſolution, that the mixture has a greater ſpecific gravity than the mean gravity of the ingredients, relatively to their reſpective quantities. Hence they occupy leſs ſpace than before, which may be ſeen by putting into a bottle any ſoluble ſalt (*e. g.* ſulphate of ſoda), and filling it to the brim with water; after the ſolution is effected, the liquor will appear to have ſunk through a certain interval below the firſt level, without any loſs of the ingredients. See AFFINITY.

When ſolutions of ſalts are congealed, the ice often affords very pretty figures; but it is to be obſerved, that the ſame ſalt does not always give the ſame figures. Thus, the ſame ſolution of verdigris, frozen by means of ſnow and ſalt, affords a different figure, from what is produced by the natural cold of the air. And the former ice being thawed, and left to freeze in the ſame phial, did not give the ſame figures as at firſt. See Boyle's Works Abridged, p. 168.

SOLUTION, in *Metallurgy*, is diſtinguiſhed into dry and moiſt. The dry ſolution is the blending imperceptibly a ſmall quantity of a metal or mineral, with a very large one of ſome other body, dry, hard, and not fluid when cold. The moiſt ſolution is the diſtributing a body through the very minuteſt parts of an aqueous, or in great part aqueous fluid, in ſuch manner, that both may turn into a fluid, to appearance homogeneous, which goes through all filters, without being detained or ſeparated by them, and the ſmalleſt part of which contains in it a proportionable quantity of both the menſtruum or diſſolvent, and of the diſſolved body. The ſolution of gold in aqua regia, and of ſilver in aqua fortis, as alſo that of any of the ſalts in water, are ſolutions of this kind. Cramer's Art of Aſſaying, p. 194.

In the making of the ſeveral metallic reſolutions, for the neceſſary proceſſes in chemiſtry, the operator is ſubject to great danger in his health, from the noxious vapours. This has been an accident complained of indeed by many, but ſcarcely attempted to be remedied or obviated by any, in a rational way, till M. Geoffroy, whoſe experiments ſubjected him greatly to the miſchief, employed his thoughts, for his own ſake, as well as that of the world in general, to the effectual prevention of it.

The diſſolution of the metals in the corroſive acid ſpirits are thoſe, which ſend out the moſt copious and moſt dangerous vapours. The exhalation of quickſilver, of antimony, and of lead and copper, are all in themſelves greatly hurtful, as well as the fiery vapours of ſpirit of nitre, ſea-ſalt, or vitriol; and if either of theſe is ſingly ſo, how pernicious muſt they need be in thoſe caſes, where two of them are joined together in ſuch a manner, as that this union ſends up infinitely more vapours than would otherwiſe ariſe; in this caſe the utmoſt care is neceſſary to prevent the chemiſt from falling a ſacrifice to his zeal for his diſcoveries.

The common way of avoiding this danger, is by making the ſolution either abroad in the open air, or in a chimney; but ſometimes theſe cautions cannot be uſed, and under ſome circumſtances they are ineffectual. This gave occaſion to M. Geoffroy to uſe a method, which he afterwards propoſed to the public, of ſtopping the riſe of the vapours entirely, or at leaſt of diminiſhing them ſo greatly, that they ſhall be harmleſs and unperceived. All that was neceſſary to this, ſeemed to him to be the contriving to cover the ſurface of the fluid with ſome body, capable of retaining thoſe vapours, yet not capable of diſturbing the operation of the menſtruum on the metal; and the common expreſſed oils of fruits, as the oil of olives, almonds, or the like, were found capable of happily performing this effect; and that particularly, as they would eaſily receive into themſelves the acid ſalts which ariſe in the conflict. The thing which gave this gentleman the hint of the diſcovery was, that in the boiling of ſugars, honey, or the like ſubſtances, when there is any danger of their boiling over the veſſel, the pouring in a little oil ſtops the ſwelling. In the metallic ſolutions it has the ſame effect; and that heightened by this good conſequence, that by keeping in the fiery vapours of the acid, it returns them back upon the metal, and by this means does, in effect, add greatly to the power of the menſtruum.

This method of uſing oil has indeed three advantages. 1. The preſerving the operator from the injuries of the vapours. 2. The greatly moderating of that violent rarefaction, which is often of ill conſequence. And 3. The ſame quantity of the menſtruum, by this means, diſſolves more of the metal. The beſt method of making ſolutions with this advantage is this: firſt, wet the ſurface of the metal to be diſſolved with water, or ſpirit of wine; then pour a little water, or ſpirit of wine, into the glaſs in which the ſolution is to be made, this will prevent the oil from ſticking to the ſurfaces of either; then put the metal into the glaſs, and pour in the oil upon it; laſt of all, pour on the menſtruum: this, being greatly heavier than the oil, will ſink to the bottom and work upon the metal, while the oil perfectly covers the whole ſurface. There is no need to be exact as to the quantity of the oil, but more or leſs is to be uſed, in proportion to the greater or leſs ebullition which the mixture is expected to make.

The air-bubbles, which ariſe to the ſurface with great impetuoſity in the making of theſe ſolutions, are here ſeen to break by degrees as they enter the covering of oil, and generally are quite diſſipated before they ariſe to the ſurface of it. The few of them which retain their figure till they arrive at the ſurface, there burſt and give a ſlight exhalation; and one may continually ſee the drops of the menſtruum falling back again out of the oil into it, after being deſerted by the bubbles of the air which had raiſed them ſo far. On the contrary, in the common way of making ſolutions, the air-bubbles puſh one another up to the ſurface, where they form a ſort of ſcum, which continually thickens by their freſh riſing and ſupporting one another, till it often riſes over the top of the veſſel. Theſe bubbles of air ſeem to be formed of ſmall particles of air extremely condenſed in the pores of the metal, which, when the particles of it are ſeparated for ſolution, find themſelves at liberty to dilate and expand, and ariſe to the ſurface in their proper form.

If it be thought neceſſary, in any ſolution which raiſes a more than ordinary quantity of vapours, to prevent the flying off of that ſmall quantity which may eſcape through the oil, there is nothing more neceſſary than to pour a little ſpirit of wine upon the oil; for the acid vapours which paſs the oil will then be received in the ſpirit, and will be dulcified in it, and inſtead of a diſagreeable odour, will yield only a very ſweet and ſafe one. Spirit of wine alone, uſed inſtead of oil, and poured gently on the ſolution, has very great effects; inſomuch, that if uſed to the ſolutions in ſpirit of nitre, which uſually ſend up very noxious and coarſe red vapours, they by this means are made to ſend up only very fine light white ones, and theſe of a very agreeable ſmell: the bubbles raiſed in this caſe are very ſmall, and uſually burſt before they arrive at the ſurface of the ſpirit. The only objection to this method is, that the ſpirit of wine ſoon mixes itſelf with the menſtruum, and there are ſome caſes in which this may be of ill conſequence to the proceſs. Mem. Acad. Par. 1719.

SOLUTIVE, Loosening, or *Laxative.* See Laxative.

SOLWAY Frith, in *Geography*, an arm of the ſea, branching off from the Iriſh ſea, and forming a conſiderable part of the boundary between England and North Britain. Reckoning it to commence at Salterneſs Point, the S.E. corner of Galloway, its breadth to the neareſt land in Cumberland is about eight miles, and its length, inland, to the eaſt, 22 miles. As its outline, however, is rather irregular, it may be conſidered as comprehending an extent of 80 miles of ſea-coaſt, of which 36 miles are on the Scottiſh ſhore and the remainder on the Engliſh ſide. This frith opens to the weſt, and is rather a troubleſome navigation, as it abounds with ſhoals. The tides here are extremely regular, ſpring tides riſing 20 feet above low water-mark, and ordinary tides about 10 or 12. Numerous rivers pour their waters into the Solway, of which the principal are the Nith, the Annan, the Eſk, and the Levin, in Scotland, and the Eden and Wampool, in England. The Solway abounds with fiſh of various kinds, but particularly with ſalmon, which are caught in great quantities, and either ſold in the neighbourhood, or ſent pickled to London and other parts of England. The modes of taking this valuable fiſh here are ſo ſingular as to deſerve a particular detail. They are four in number, firſt with leiſters, a kind of four-pronged fork, with the prongs turned a little to one ſide, having a ſhaft from 20 to 24 feet long; theſe the fiſhermen run along the ſand on the edge, or throw them when they ſee any fiſh; in this manner they kill or wound great numbers. Some of the people are very dexterous at this exerciſe; inſomuch that, according to Mr. Pennant, they will on horſeback, at full gallop, throw a leiſter, and kill at a great diſtance. 2. By *heaving* and *hauling*, that is, by ſtanding in the current of the tide with ſmall hand-nets. 3. By fixing ſmall pock-nets to ſtakes in the currents. Theſe nets are made with wide meſhes, and the fiſh that come rapidly down with the ſtream, inſtantly run their heads into the meſhes, from whence they are unable to diſengage themſelves. The other method is the common one uſed in other parts for catching ſalmon. Sinclair's Statiſtical Account of Scotland, 8vo. 1796. General Report of Scotland, 8vo. 1814. Hiſtory and Antiquities of the Counties of Weſtmoreland and Cumberland, 4to. by Joſeph Nicholſon, eſq. and Richard Burn, LL.D.

Solway *Moſs*, a tract of land in Cumberland, England, is entitled to ſome notice in this place on account of the extraordinary effects of its eruption in the year 1771. Mr. Gilpin, in his "Obſervations on the Mountains and Lakes of Cumberland," &c. two vols. 1781, thus deſcribes the nature of the place and the particulars of the inundation. "Solway Moſs is a flat area, about ſeven miles in circumference. The ſubſtance of it is a groſs fluid, compoſed of mud, and the putrid fibres of heath, diluted by internal ſprings, which ariſe in every part. The ſurface is a dry cruſt, covered with moſs and ruſhes; offering a fair appearance over an unſound bottom, ſhaking with the leaſt preſſure. Cattle, by inſtinct, know and avoid it. Where ruſhes grow the bottom is ſoundeſt: the adventurous paſſenger, therefore, who ſometimes, in dry ſeaſons, traverſes this perilous waſte, to ſave a few miles, picks his cautious way over the ruſhy tuſſocks, as they appear before him. If his foot ſlips, or if he ventures to deſert this mark of ſecurity, it is poſſible he may never more be heard of. On the ſouth, Solway Moſs is bounded by a cultivated plain, which declines gently through the ſpace of a mile to the river Eſk. This plain is lower than the moſs, being ſeparated from it by a breaſt-work formed by digging peat, which makes an irregular though perpendicular line of low black boundary. It was the burſting of the moſs through this peat breaſt-work, over the plain between it and the Eſk, that occaſioned the dreadful inundation which deſtroyed ſo large a diſtrict. The more remarkable circumſtances relating to this calamitous event were theſe: On the 13th of November, 1771, in a dark tempeſtuous night, the inhabitants of the plain were alarmed with a dreadful craſh, which they could no way account for: many of them were then in the fields watching their cattle, leſt the Eſk, which was then riſing violently in the ſtorm, ſhould carry them off. In the mean time, the enormous maſs of fluid ſubſtance, which had burſt from the moſs, moved ſlowly on, ſpreading itſelf more and more, as it got poſſeſſion of the plain. Some of the inhabitants, through the terror of the night, could plainly diſcover it advancing like a moving hill. This was in fact the caſe; for the guſh of mud carried before it through the firſt two or three hundred yards of its courſe a part of the breaſt-work; which, though low, was yet ſeveral feet in perpendicular height; but it ſoon depoſited this ſolid maſs, and became a heavy fluid. One houſe after another it ſpread round, filled and cruſhed into ruin, juſt giving time to the terrified inhabitants to eſcape. Scarcely any thing was ſaved except their lives; nothing of their furniture, few of their cattle. Some people were even ſurpriſed in their beds, and had the additional diſtreſs of flying naked from the ruin. The morning light explained the cauſe of this amazing ſcene of terror, and ſhewed the calamity in its full extent: and yet, among all the conjectures of that dreadful night, the miſchief which really happened had never been ſuppoſed. Lands which in the evening would have let for twenty ſhillings an acre, in the morning were not worth ſixpence. On this well-cultivated plain twenty-eight families had their dwellings and little farms; every one of which, except perhaps a few who lived near the ſkirts of it, had the world totally to begin again. Who could have imagined, that a breaſt-work, which had ſtood for ages, ſhould at length give way? or that thoſe ſubterranean floods which had been bedded in darkneſs ſince the memory of man, ſhould have ever burſt from their black abode? This dreadful inundation, though the firſt ſhock of it was moſt tremendous, continued ſtill ſpreading for many weeks, till it covered the whole plain, an area of five hundred acres; and, like molten lead poured into a mould, filled all the hollows of it, lying in ſome parts thirty or forty feet deep, reducing the whole to one level ſurface." The plain that was covered with this Stygian torrent, has, however, ſince been reſtored to fertility by the exertions of a Yorkſhireman named Wilſon, whoſe ſelf-taught genius at once conceived a novel plan, and directed its execution.

This plan was ſimple and eaſily executed. Wilſon had two large reſervoirs formed in the higher grounds, filled them with water, and directed the whole body and force of it, firſt againſt a large knoll in front of Netherby houſe, and afterwards againſt the maſſes of accumulated moſs, all of which were progreſſively carried away into the channel of the river Eſk. Further particulars may be ſeen in Gilpin's work, already referred to. Pennant's Tour to Scotland.

The vicinity of Solway Moſs became celebrated from the defeat of the Scottiſh army under the command of Oliver Sinclair, in the reign of Henry VIII. The whole army was either taken or diſperſed; and a few fugitives are ſaid to have periſhed in the moſs, into which they had plunged to eſcape the ſword.

SOLYHULL. See SOLIHULL.

SOLYMA, in *Ancient Geography*, a name ſometimes given to *Jeruſalem;* which ſee.

SOLYMAN, in *Geography*. See SOLIMAN.

SOLYMANIA, a diſtrict of that portion of the pachalic of Bagdad beyond the Tigris, which comprehends almoſt the whole of ancient Aſſyria proper, and is now denominated the Lower Kurdiſtan; extending from Armenia and the territories of the chief of Julamerick to the diſtrict of Mendeli, which is its frontier, towards Kuziſtan or Chuſiſtan. Each of the eight diſtricts into which this province is divided has a ſeparate hakem, or governor; but he who reſides at Solymania rules over the greateſt portion of territory; and as he muſt, by birth, be a Kurd, he uſually aſſumes the title of paſha of Kurdiſtan. The town of "Solymania a Shehr e Zour," deſignated in the retreat of Heraclius by the appellation of Siazuros, is diſtant 18 leagues E. of Kerkook. It is the reſidence of Solyman, paſha of Kurdiſtan, a diſtinguiſhed warrior, who, in 1810, at the inſtigation of the Porte, took arms againſt his maſter, the paſha of Bagdad, whom he defeated and put to death. Shehr e Zour, having fallen into decay, was ſome years ago rebuilt by Solyman, paſha of Bagdad, and ſince that time has aſſumed his name. It is ſituated in a delightful country, cloſe to the foot of mount Zagros, and contains about 6000 inhabitants. Not far from Solymania was the city of Holwan, the retreat of Yezdejird, after the battle of Cadeſia, and to which the caliphs of Bagdad were accuſtomed to retire during the heats of ſummer. It was ruined by Holaku, and has never ſince recovered its conſequence.

SOLYME, in *Ancient Geography*, a town beyond Jordan, in the diſtrict of Gaulon. Joſephus.

SOLYMI, an ancient and venerable people, mentioned by Homer, and the poet Chœrilus, who ſpoke Phœnician, cut their hair round, and inhabited the Solymean mountains, near a large lake. Theſe marks, according to Joſephus and Tacitus, agree with the Jews, called Solymi, on account of their capital city Jeruſalem:—a nation remarkable for the ſingularity of their laws and of their actions, ſpeaking Phœnician or Hebrew, dwelling in a mountainous country near Jeruſalem, ſituated in the mountains and near the Aſphaltite lake. Theſe tokens, according to other learned men, do not deſignate Jews. Hence ſome think, that they were Moabites, or Midianites, bordering on the Aſphaltite lake, and reckoned among the Arabians, who cut their hair round in a circle. Others think that the Solymean mountains were in Piſidia, near Lycia; and that we muſt here ſeek the Solymi of Homer and Chœrilus.

SOMA, in *Commerce*, a corn meaſure at Bergamo in Italy, which is divided into 8 ſetari, and contains $4\frac{2}{3}$ buſhels, Engliſh meaſure. In the iſland of Corſica, it is a wine meaſure; the barile being = 2 ſome = 12 zucchi = 108 pinte = 432 quarti.

SOMA, in *Hindoo Mythology*, is the regent of the moon, being in India a male deity, like the Mona of the Saxons, and the Lunus among ſome of the nations who ſettled in Italy. The Hindoos have however a female moon, as the conſort of Soma or Chandra: ſhe is named Chandri, being, in their ſtyle of perſonification, the ſakti, or energy of her lord. (See SAKTI.) Chandra is a name as often uſed as Soma, perhaps oftener, and is the common name of the moon in ſeveral dialects of India. Chandri is ſometimes identified with the goddeſs Parvati, conſort of Siva, and in pictures of that god ſhe is often ſeen in the form of a creſcent ornamenting his head; he is thence named Chandraſekra, or moon-crowned. In the Hindoo theogonies, Soma is ſtated to be the ſon of a Riſhi named Atri, ſon of Brahma: and Boodh, or Mercury, is the ſon of Chandra; Boodh, or Budha, was married to Ila, daughter of the ſeventh Menu, named Satyavrata. Soma is ſometimes ſaid to be the ſon of Surya, or the ſun, having ſprung from a ray of that glorious luminary. According to another legend, it was a flaſh of light from the eye of Atri that impregnated a goddeſs, who is found to be a perſonification of the via lactea, or ſpace, who thence bore Soma. So that the Hindoo Soma is both huſband, wife, and offspring of the ſun. See ILA.

Soma is often invoked in the religious ceremonies of the Brahmans, and receives a ſhare in the offerings with which ſuch ceremonies often are accompanied. He is ſometimes ſtyled lord of plants, eſpecially of medicinal plants. We may notice here, as connected with ſome ſuppoſed coincidences in Iriſh and Indian mythology, that *Som* in the former is the deity preſiding over plants, the ſame as in India; for the Sanſcrit has merely a grammatical termination: the names are radically alike. (See SURYA and TRIVENI). One very myſterious vegetable is peculiarly ſacred to the Hindoo Soma: it is called *Somalata*. Soma, like the moon of weſtern mythologiſts, preſides in India over Monday, which day is called Somvar in many dialects. See ZODIAC.

The lunar deity of the Eaſt is uſually pourtrayed in a car drawn by a pied antelope, his head encircled by a ſilver creſcent, and ſometimes with a rabbit on his banner. He is commonly ſeen four-handed, ſometimes holding a lotos, a club, a diſcus, and ſhell, the uſual attributes of Viſhnu; though he ſeems in a greater degree connected with *Siva*, which ſee. He is alſo frequently ſeen with Chandra's emblem, the antelope, in his hand, which emblem is called Saſin. (See SASIN.) A creſcent on his forehead, and on the foreheads of his conſort and offspring, is alſo a Sivean family diſtinction. The idea of a male and female moon has given birth to many poetical fancies and allegories. Iſa and Iſi, under their names of Chandra and Chandri, undergo ſeveral ſexual and other metamorphoſes. Chandra, or Deus Lunus, is the moon when in oppoſition to the ſun; and Chandri, or Dea Luna, when in conjunction.

In the ſol-lunar legends of the Hindoos, the ſun is, as we have ſhewn, ſometimes male, ſometimes female; and both wife and huſband of Lunus and Luna, under their ſeveral names of Surya, Savitri, Chandra and Chandri.

Chandri, who concealing herſelf in Somagiri, or the mountain of the moon, was there viſited by Surya, the ſun; from which conjunction aroſe a numerous family called Pulinda. See ILA and ROHINI.

The Hindoos have a fable that the moon is a vaſe of nectar, and draw many pleaſing figures from this poetical ſource: hence nectar-beaming is an epithet or name of Soma. (See SASIN.) Other names or titles of Soma are Himanſu, Indu, Saganka, Saſanka, and Suſhumna. A ſimilar idea of deriving ambroſia, or inſpiration from the moon, is traceable in the poetics of Greece. The Hindoos call this immortal beverage *Umrita;* which ſee.

Images of Chandra are not often ſeen. He has been noticed among the ſculptures in the cavern temple on Elephanta, and pictures of him are not rare. He is repreſented young and handſome; and it is very common for poets, both Hindoo and Mahometan, to compare their miſtreſſes to the full moon; this is perhaps common to almoſt all nations.

In Hindoo hiſtories and theogonies, mention is made of numerous races, offspring of the ſun and moon, and ſeverally called Suryavanſa and Chandra-vanſa. (See SURYAVANSA.) It is common in works of antiquity to ſee it noticed whether the heroes be of the ſolar or lunar race, but ſuch diſtinctions are little regarded in modern times. Auſterities are common to Hindoo devotees, in expiation of offences, or as ſecurity from evil. (See TAPAS.) One ſpecies of it is named Chandrayana, or the lunar penance. It conſiſts in the ſinner or devotee "eating for a whole month no more than thrice eighty mouthfuls of wild grains, as he happen to meet with them, keeping his organs in ſubjection." The reward, according to Menu, is attaining the ſame abode as the regent of the moon; and it abſolves a Brahman from the ſin of ſlaughtering a thouſand ſmall animals which have bones, or of boneleſs animals as many as will fill a cart: and it is alſo the expiation for killing a Sudra, an individual of the fourth or ſervile claſs. See SUDRA.

SOMADEVA, a name of the Hindoo regent of the moon, who is called alſo Chandra, Soma, and by ſeveral other names. (See the preceding article.) It is likewiſe the poetical appellation of a celebrated Indian writer, mention of whom is briefly made under the article TRIVENI.

SOMAINPOUR, in *Geography*, a town of Hindooſtan, in the circar of Gohud; 25 miles S.E. of Calpy.

SOMAISSON, a town of Hindooſtan, in Myſore; 22 miles W. of Bangalore.

SOMALATA, in *Botany*, is the Sanſcrit name of the aſclepias acida, or cynanchum viminale, of our ſyſtems; a vegetable highly venerated by the Hindoos. The name means *moon-plant:* it is ſacred to Soma, or the moon, and is of ſuch profound and myſterious alluſion, that none but Brahmans may preſume to taſte its juice. It is gathered, expreſſed, and drank, with many ſuperſtitious ceremonies; and alluſions to it are frequent in the writings of the Hindoos, who are ſaid to conſider it as typical of the umrita or ambroſia, obtained in ſo poetical a manner by the gods, and quaffed by them as the beverage of immortality. (See UMRITA.) "O thou who quaff the invigorating juice of the ſomalata," is an invocation to Brahmans, met with in Sanſcrit books; a farther examination of which would perhaps lead to a ſurmiſe, if not to a concluſion, that the myſteries connected with this holy vegetable in India are nearly ſimilar to thoſe related of our druids with their myſterious miſtletoe. It is noticed under the article SOMA, that the Hindoos believe the moon to have great influence on vegetation in general, eſpecially on the ſomalata, or moon-plant, of which he is the particular lord; as well as generally of all vegetables.

SOMALPET, in *Geography*, a town of Hindooſtan, in Berar; 55 miles N.N.E. of Mahur.

SOMANAPILLY, a town of Hindooſtan, in Myſore; 18 miles S. of Bangalore.

SOMANOOR, a town of Hindooſtan, in Coimbetore; 15 miles N.E. of Coimbetore.

SOMASQUO, *Fathers of*. See FATHERS.

SOMBAR, in *Geography*, a town of Perſia, in the province of Irak; 114 miles S.W. of Hamadan.

SOMBERNON, a town of France, in the department of the Cote d'Or, and chief place of a canton, in the diſtrict of Dijon; 13 miles W. of Dijon. The place contains 755, and the canton 7770 inhabitants, on a territory of 235 kiliometres, in 28 communes.

SOMBOR, a town of Auſtrian Poland, in Galicia; 6 miles W. of Halicz.

SOMBRERA, a ſmall iſland in the Weſt Indies, about 13 miles N. of Anguilla, dependent on Barbuda. N. lat. 18° 40′. W. long. 63° 25′.

SOMBRERE CHANNEL, a channel between the Nicobar iſlands. N. lat. 7° 32′ to 7° 50′. E. long. 94°.

SOMBRERETE, a town of Mexico, in the province of Zacatecas; 55 miles N. of Zacatecas. N. lat. 23° 40′. W. long. 4° 2′.

SOMBRERO, a river of Africa, which runs into the Atlantic, N. lat. 4° 40′. E. long. 5° 52′.—Alſo, a rock in the ſea of Mindoro. N. lat. 10° 49′. E. long. 121° 27′.

SOM-CHAN, a town of Chineſe Tartary. N. lat. 41° 2′. E. long. 120° 42′.

SOMEBODY KNOWS WHAT, a name given to the extremity of the arm of Duſky bay, which captain Cook calls "Nobody knows what." This name was given by captain Vancouver, who examined and found two inlets, or at leaſt a large branch, divided by a ridge of land through its whole length.

SOMEER, a town of Hindooſtan, in the circar of Gohud; 10 miles S.E. of Lahaar.

SOMEGILL, a river of Wales, which runs into the Lug below Preſteign, in Radnorſhire.

SOMENSHAR, a town of Little Bucharia; 15 miles N.W. of Hami.

SOMERA, a town of Sweden, in Tavaſtland; 33 miles S.W. of Tavaſthus.

SOMERFELT, a town of Pruſſia, in Oberland, W. of Liebſtadt.

SOMERGEM, or SOMMERGEM, a town of France, in the department of the Scheldt, and chief place of a canton, in the diſtrict of Gand or Ghent; 9 miles N.W. of Ghent. The place contains 6221, and the canton 18,800 inhabitants, on a territory of 125 kiliometres, in 7 communes.

SOMERS, John, *Lord*, in *Biography*, a diſtinguiſhed lawyer and ſtateſman, born at Worceſter, in 1652, was the ſon of a reſpectable attorney of that city. He received his early education at the public ſchool of his native city; and, at a proper age, he was entered a gentleman-commoner of Trinity college, Oxford. He quitted the univerſity without a degree, but he had attained a good taſte for polite literature, and being deſtined by his father for the legal profeſſion, he ſpent ſome time as a clerk to ſir Francis Winnington, an eminent lawyer, after which he removed to the Middle Temple. When called to the bar, he diſplayed thoſe talents which enſured his arriving at profeſſional diſtinction: at the ſame time, though extremely diligent in his legal ſtudies, he did not abandon his claſſical purſuits, but tranſlated the hiſtory of the life of Alcibiades, and Ovid's Epiſtle of Ariadne to Theſeus.

He was an ardent friend of liberty, and in the latter part of the reign of Charles II. he wrote ſome political tracts; which, though they appeared without his name, were aſcertained to be from his pen.

A piece entitled "The Security of Engliſhmen's Lives; or the Truſt, Power, and Duty of the Grand Juries of England, explained according to the Fundamentals of the Engliſh Government," was attributed to him by Mr. Walpole, and is thought to be the ſame with one alluded to by biſhop Burnet, written in conſequence of the grand juries return of *ignoramus* to the bill againſt lord Shafteſbury. He was moreover the reputed author of "A brief Hiſtory of the Succeſſion of the Crown of England, collected out of the Records," the object of which was to prove the right of parliament to regulate the deſcent of the crown, with the view of ſupporting the intended excluſion of the duke of York, on account of his religion. In 1681 he took part in publiſhing "A juſt and modeſt Vindication of the Proceedings of the two laſt Parliaments," originally written by Algernon Sidney, but new-modelled by him. He was counſel, in 1683, for the ſheriffs of London, and for other perſons who were proſecuted for a riot in the city at the election of ſheriffs. After the acceſſion of James II. he continued the firm oppoſer of the arbitrary meaſures of the court, and obtained great credit as one of the counſel for the ſeven biſhops. He moſt heartily concurred in the event of the revolution, and was one of the confidential adviſers of the meaſure for bringing over the prince of Orange. He ſat as repreſentative of his native city in the convention-parliament, and was appointed one of the managers for the houſe of commons, in the conference held with the lords concerning the word *abdicate*, and his acute and ſenſible obſervations on the ſubject were greatly admired. In 1689 he was knighted, and made ſolicitor-general, and while he held that high poſt, delivered a ſpirited and ſeaſonable ſpeech in favour of the act of convention for recognizing William and Mary, the legality of which had been called in queſtion by a member of the houſe of commons. In 1692, the office of attorney-general was conferred upon him, and in the following year that of lord-keeper of the great ſeal. When advanced to the bench, his behaviour was that of an able and upright magiſtrate, whoſe love of juſtice was tempered with ſingular mildneſs and condeſcenſion. At the ſame time he was in the higheſt credit with the ſovereign, and he made uſe of his influence to ſerve perſons of merit. He was a patron to Mr. Addiſon, and obtained for him an allowance to enable him to make that tour in Italy, of which he has printed an account. In 1695 he was advanced to the lord chancellorſhip of England, and was raiſed to the peerage by the title of lord Somers, baron Eveſham. At the ſame time he obtained certain grants from the crown, a circumſtance which has drawn upon him ſome cenſure; though, without this addition, his advancement to the peerage would have been a puniſhment inſtead of reward, inaſmuch as it would have been impoſſible for him to have maintained his rank in the peerage.

Lord Somers was now regarded as the head of the Whigs, and it was his aim to moderate the heat and jealouſy of that party, and conciliate to it both the king and nation; hence it has been averred that he was too compliant in ſome points to the royal pleaſure; which, however, did not prevent his being made a ſacrifice when the Tories came into power. His acquieſcence in the firſt partition treaty in 1699, with other miniſterial meaſures, produced great complaints againſt him in parliament, and an addreſs was moved in the houſe of commons, praying the king that lord Somers might for ever be removed from his majeſty's preſence and council. This motion was, however, defeated by a large majority; but the king, ſoon after, to quiet the diſcontents, deſired him voluntarily to reſign his ſeals. This he refuſed; and he was accordingly diſmiſſed from his office. In 1701 the houſe of commons ſent up to the lords an impeachment of lord Somers, which, however, was diſmiſſed by the peers, and the proſecution was not reſumed. Very ſhortly after this the king died, and the new reign not being favourable to the principles of lord Somers, he ſpent his time in literary retirement, and during this period of leiſure he was elected preſident of the Royal Society. He was not, however, inattentive to public concerns, and vigorouſly oppoſed the bill brought into parliament by the high church party, to prevent occaſional conformity. In 1706 he drew up a plan for effecting an union between England and Scotland, which was ſo much approved, that queen Anne nominated him one of the managers for carrying that meaſure into execution. He is alſo ſaid to have had a conſiderable ſhare in the bill of regency, by which the Proteſtant ſucceſſion to the crown was extended and ſecured. Upon a change of miniſtry in 1708, lord Somers was nominated to the poſt of preſident of the council, from which he was diſmiſſed in 1710; and though he continued for ſome time to take an active part in the buſineſs of the houſe of peers, it was not very long before a decline in the ſtate of his health and faculties rendered him unfit for public buſineſs. He died in 1716, at the age of 64. The memory of lord Somers is ſtill held in high veneration by the friends of conſtitutional liberty; to the eſtabliſhment of which, by means of the revolution and Proteſtant ſucceſſion, no individual contributed more than he. His abilities were very conſiderable, his manners highly ingratiating, and, notwithſtanding the oppoſition which he had occaſionally to encounter, few ſtateſmen have paſſed through life with a purer character. He made a large collection of ſcarce and curious pamphlets, of which there has been publiſhed a ſelection in four parts, each conſiſting of four volumes, 4to. His collection of original papers and letters was unfortunately deſtroyed by a fire, which happened in the chambers of the Hon. Charles Yorke, on the 27th of Jan. 1752. Biog. Brit.

Somers, in *Geography*, a townſhip of America, in Connecticut, and county of Tolland, containing 1210 inhabitants; 24 miles N.E. of Hartford.—Alſo, a poſt-townſhip of New York, on the N. line of Weſt Cheſter county, 50 miles N. of New York, and 120 from Albany; bounded N. by Ducheſs county, E. by North Salem and South Salem, S. by Bedford and New-Caſtle, and W. by York or Yorktown. Its name, which was formerly Stephentown, was changed in 1808.

1808. Here are four grain-mills, five or ſix ſaw-mills, two fulling-mills, a paper-mill, and ſeveral fine ſcites ſtill unoccupied. The ſoil of this townſhip is generally very good, and adapted to produce a great variety of agricultural products. Here are alſo a printing eſtabliſhment, that iſſues a weekly paper, the poſt-office, and a ſmall collection of houſes. This village is the principal market of lean ſtock of cattle and ſheep, brought hither from diſtant parts of the country, for the ſupply of the ſales of fattened cattle and ſheep to the butchers of New York. The farmers of this country carry on an extenſive traffic in this way, and droves are annually and almoſt conſtantly arriving from the inland regions, at the diſtance of 100, 200, and even 300 miles, to replace the conſumption. The whole population conſiſts of 1782 perſons.—Alſo, a townſhip of Prebble county, in the ſtate of Ohio, containing 719 inhabitants.

Somers *Iſlands*. See Bermudas.

SOMERSDORF, a town of Germany, in the margraviate of Anſpach; 5 miles S. of Anſpach.

SOMERSET, *Duke of*, in *Biography*, according to Kircher (tom. i. lib. vi. p. 486.) and Printz, in his Germ. Hiſt. Muſ. invented in 1649 a new ſpecies of violin, with eight ſtrings; which contained all the moſt excellent ſecrets of muſic, and raviſhed every hearer.

Somerset, in *Geography*, a well-cultivated county of New Jerſey, in America, on the N. ſide of the great road from New York to Philadelphia. The ſoil, eſpecially on Rariton river and its branches, is good, and produces good crops of wheat, of which great quantities are annually exported. It is divided into ſeven townſhips, and contains 14,728 inhabitants, including 1968 ſlaves. The capital of the above county is ſituated on the W. ſide of Millſtone river, and contains a court-houſe, gaol, and about 20 houſes; 13 miles N. of New Brunſwick.

Somerset, a county of Maryland, bounded E. by the ſtate of Delaware and Worceſter county, and W. by the waters of Cheſapeak bay. It contains 17,195 inhabitants, including 6975 ſlaves. Waſhington Academy, in this county, was inſtituted by law in 1779: it was founded and is ſupported by voluntary ſubſcriptions and donations, and is authoriſed to receive gifts and legacies, and to hold 2000 acres of land.

Somerset, a county of Pennſylvania, bounded N. by Huntingdon, and S. by Alleghany county, in Maryland; it is divided into 15 townſhips, and contains 11,284 inhabitants.

Somerset, a townſhip of the above county, containing 1548 inhabitants; and alſo a borough, containing 489 inhabitants.

Somerset, a county of the ſtate of Maine, containing 12,910 inhabitants.—Alſo, a townſhip of Waſhington county, in Pennſylvania, containing 1500 inhabitants.—Alſo, a townſhip of Windham county, in Vermont, containing 199 inhabitants; 10 or 12 miles N.E. of Bennington.

Somerset, or *Sommerſett*, a poſt-town of Briſtol county, in Maſſachuſetts, on Taunton river; incorporated in 1790, and containing 1199 inhabitants; 49 miles S.E. of Boſton.

SOMERSETSHIRE, one of the maritime counties of England, is ſituated in the ſouth-weſtern part of the kingdom, and is bounded by the Briſtol Channel and Glouceſterſhire on the north, by Wiltſhire on the eaſt, by Devonſhire on the ſouth-weſt, and by Dorſetſhire on the ſouth-eaſt. It is of an oblong form, and extends in length from north-eaſt to ſouth-weſt about 80 miles, and in breadth, in an oppoſite direction, about 36 miles; the circumference is ſomething more than 200 miles, and the ſuperficial contents about one million of acres.

Ancient Inhabitants, and hiſtorical Events.—This diſtrict, as well as its borders, is ſaid to have been, in early times, inhabited by the Belgæ, a people of Celtic origin, who migrated hither from Gaul about three centuries prior to the Chriſtian era. They are deſcribed as having eſtabliſhed colonies, cultivated lands, and inſtructed ſuch of the natives as choſe to aſſociate with them in the arts of induſtry. Their dominion was greatly extended about 250 years after their firſt ſettlement, when Divitiacus, king of the Sueſſones, brought over from the continent a conſiderable number of their countrymen. To appeaſe the hoſtilities which had ſubſiſted between theſe ſettlers and the native inhabitants, a treaty was now concluded, and a line or boundary made, to determine their reſpective territories. This line was perpetuated by a large and deep foſſe, called, from the circumſtances of its origin, Wanſdike; parts of which are ſtill conſpicuous in Wiltſhire, &c. It is ſaid to commence near Andover, in Hampſhire, and terminate at the Severn ſea, at Portiſhead, in this county; being an extent of about 80 miles. On Marlborough Downs this ſingular dike appears nearly in its priſtine ſtate, being exceedingly deep, and flanked by a lofty mound, or rampart, on its ſouth ſide. According to this demarcation, the Belgæ occupied a great part of this county: and of their chief cities, Ivelcheſter, Bath, and Wincheſter, the two former are within its limits. Their contentions with the people, whoſe poſſeſſions they had uſurped, laſted till the arrival of the Romans in Britain, when the oppreſſors, in their turn, became the oppreſſed. The Cangi, a tribe of thoſe Belgæ who migrated hither under Divitiacus, were nearly annihilated by the Romans, nine years after their invaſion. Many remains within this diſtrict bear teſtimony to the characteriſtic activity of the Romans, in eſtabliſhing ſtations, marking out camps, and founding colonies. Beſides their cities of Aquæ Solis or Bath, and Iſcalis or Ilcheſter, there are many places which, though their ancient names are loſt, bear evident marks of a Roman origin, in the foundation of walls, and in various remains that have from time to time been diſcovered. Their principal road through this county was the Foſſe, which extended from Bath, in a ſouth-weſterly direction, to Perry-ſtreet, on the confines of Devonſhire. In a direction nearly parallel to it another road paſſed from the foreſt of Exmoor, through Taunton, Bridgewater, and Axbridge, to Portiſhead; whence there was a trajectus acroſs the Briſtol Channel, to the city of Iſca Silurum, now Caerleon. A third road, called Via Julia, extended from Bath to Briſtol and the Severn; and a fourth communicated from the former ſtation to Portiſhead. Upwards of twenty-three Roman encampments are enumerated in this county. During the dominion of the Romans, it formed part of the province of Britannia Prima. On the decline of their power, and their evacuation of the country, in the fifth century, it became ſubject to the Saxons, who incorporated it with their kingdom of Weſſex. It is noted as being one of the diſtricts in which the Chriſtian doctrines were propagated at an early period; and, according to ancient authors, king Ina, who began his reign over the Weſt Saxons in 688, built a college at Wells. His ſucceſſor, Kenulph, converted it into an epiſcopal ſee, and built the celebrated abbey of Glaſtonbury. But in thoſe obſcure and barbarous times, the progreſs of Chriſtianity was neceſſarily ſlow and uncertain; for it was not only oppoſed by ſuperſtition, but thwarted by ſanguinary wars. The incurſions of the Danes kept the country in a ſtate of continual alarm, and threatened its total ſubjugation. In the reign of Alfred, they deſolated almoſt every province of Britain, and at length carried their ravages into the counties of Somerſet, Wilts, and Hants; which had hitherto remained ſafe againſt their encroachments. The young king was conſtrained to relinquiſh his throne, and to preſerve himſelf by diſguiſe and concealment. He retired to an obſcure part of this county, and lived in the houſe of a neatherd. During his reſidence here an incident occurred, which, though trivial in itſelf, has been thought ſufficiently intereſting to be recorded in hiſtory, and has been given in this work under ALFRED. At the general diviſion of the kingdom into ſhires and hundreds, this province retained the name of Somerſetſhire, which the Saxons had given it; and which was probably derived from Somerton, at that time the chief town.

In the Saxon times, this county was ſubject to certain officiary earls, who had authority to try and decide cauſes, and puniſh malefactors, within their juriſdiction. The firſt earl of Somerſet was a warlike chief, named Hun, who attended king Egbert in his war with Beornulf, king of Mercia, and was ſlain in the battle of Ellendune, A.D. 823. At the period of the Norman conqueſt, when the Saxon nobles were, for the moſt part, deprived of their honours and eſtates, this county was beſtowed on ſeveral chiefs who aſſiſted William in his enterpriſe, either with troops or money. In this diſtribution, ſir William Mohun obtained by far the greateſt ſhare; for, beſides the caſtle of Dunſter, he held ſixty-one lordſhips, and had forty-ſeven knights in his retinue. He likewiſe received the title of earl of Somerſet, which devolved on his deſcendant, ſir Reginald de Mohun. In the ſanguinary conteſts between the houſes of York and Lancaſter, the inhabitants of Somerſetſhire were particularly active in behalf of the latter; in conſequence of which, it is ſaid, that after Henry VII. was advanced to the throne, he encouraged and patronized the erection of ſome ſplendid towers and churches in this county. During the civil war in the reign of Charles I., Somerſetſhire had its full ſhare of diſſention and calamity. Various ſkirmiſhes were fought, but no general engagement took place, except one at Lanſdown, near Bath, between the parliament's army, under ſir William Waller, and the king's forces, under the marquis of Hertford. In this action, out of two thouſand horſe the marquis loſt fifteen hundred, by a regiment of cuiraſſiers, commanded by ſir Arthur Hazlerig, which was ſo completely armed, that they were called the regiment of lobſters. The marquis, however, drove ſir William from his poſt, and compelled him to retire into Bath. Somerſetſhire was alſo the principal theatre of the rebellion of the duke of Monmouth, in 1685.

Surface, Marſhes, Soil, &c.—The ſea-coaſt of Somerſetſhire is very irregular, in ſome places projecting into lofty and rocky promontories, and in others receding into fine bays, with flat and level ſhores. From Stert-Point northward the coaſt is flat, and compoſed of vaſt ſand-banks repelling the inundation of the ſea, which, in ancient times, waſhed over theſe ſhoals, and flowed up into the country, covering with its waters that extenſive tract of land, now called Brent-Marſh. The ſea, after its general retirement, however, frequently overflowed theſe parts; and it was found neceſſary, for the ſecurity of the country, to eſtabliſh a commiſſion of ſewers, the members of which were required to examine the ſea-banks, ditches, gutters, and ſewers, connected with the ſea, and order the requiſite cleanſings and reparations. The firſt commiſſion of this kind upon record, was in 1304; and ſimilar offices are extended to this day. For fertility of ſoil and general produce, this county ſtands eminently high in reputation. The plains are remarkable for their luxuriant herbage, which furniſhes not only a ſufficiency for home conſumption, but alſo a conſiderable ſurplus for other markets. London, Briſtol, Saliſbury, and other cities and towns of the kingdom, are annually ſupplied from Somerſetſhire, with fat oxen, ſheep, and hogs, together with cyder, cheeſe, butter, and many other articles in great abundance. Nor are the hills deficient in arable productions; yet the vicinity of the Briſtol Channel, which fills the air with watery vapours unfavourable to the ripening of corn, particularly in the weſtern parts, induces a preference of grazing and dairy huſbandry; and, in conſequence, vaſt quantities of grain are purchaſed from the adjacent counties of Wilts and Dorſet, to the amount of at leaſt one hundred thouſand quarters annually. The ſurface of the inland parts is varied by lofty hills, rich level plains, and aſpiring woods. The principal hills are the Quantock, between Taunton and the Briſtol Channel; Brendon, near Quantock; Poulden, near Bridgewater; Mendip, between Frome and the coaſt; Broadfield-Down, between Briſtol and Wrington; Leigh-Down, in the hundred of Portherry; Dundry, near Briſtol; Lanſdown, near Bath; White-Down, near Chard; and Black-Down, on the borders of Devonſhire. The reſpective ſoils of theſe may be thus ſtated: Quantock, a thin variable ſoil, covering a looſe ſhelly rock, interſperſed with occaſional limeſtone; Poulden, a ſtrong ſurface, covering a bed of clay or marle; Mendip, Broadfield, and Leigh-Down, a gravelly loam on a limeſtone rock; Lanſdown, a thin ſoil on a freeſtone grit; White-Down, variable; Black-Down, a thin ſurface of black earth on a bed of ſand or gravel. Almoſt every ſpecies of ſoil (chalk excepted, of which there is only a ſmall portion in the eaſtern diviſion) may be found in different parts of the county, and of a quality highly fertile and productive.

Foreſts and Moors.—The ancient foreſts of Somerſetſhire were, Selwood, near Frome; Mendip, between Frome and the Briſtol Channel; Exmoor, between the port of Watchet and the north-weſt part of Devonſhire; but moſt of theſe formerly wooded tracts of country are now deprived of their ancient timber-trees, and incloſed. The principal moors are, King's-Sedgemoor, near Bridgewater; Eaſt-Sedgemoor, between Wells and Glaſtonbury; Weſt-Sedgemoor, between Taunton and Langport; North-moor and Stan-moor, near the iſle of Athelney; Common-moor, near Langport; Weſt-moor, Curry and Hay-moor, near North-Curry; King's-moor, between Ilcheſter and Somerton; Ile-moor, on the river Ivel; Brent-Marſh, on the rivers Brue and Ax; Weſton-moor, near Uphill; Banwell and Smeath-moors, near Churchill; Kenn-moor, near Yatton; Nailſea-moor, north of Kenn; Clapton-moor, between Clapton and Wirton. Of theſe, many have been incloſed, drained, and improved within the courſe of the laſt forty years.

Minerals, &c.—This county produces lead, copper, iron, lapis calaminaris, manganeſe, coal, limeſtone, paving-ſtone, tiling-ſtone, freeſtone, fullers'-earth, marle, and ochre. The Mendip hills are noted for their mines, particularly of lead and lapis calaminaris. The former ſeem nearly exhauſted, or at leaſt the deep working is ſo incumbered with water, that little can be done, and in all probability millions in value may remain concealed in the bowels of this mountain. In times paſt many thouſand pounds have been paid to the ſee of Wells for the lord's ſhare (that is one-tenth) of the lead dug on the foreſt within the pariſh of Wells only.

Coal is abundant in the north-eaſtern part of the county. In the northern collieries, the ſtrata of coal form an inclination in the plane of about nine inches in the yard. In thickneſs, it varies from ten inches to upwards of three feet: if leſs than fifteen inches they are ſeldom worked. Coal is now working generally from ſeventy to eighty fathom in depth: in a few places deeper; and by the late introduction of machinery to raiſe it by the ſteam-engine, a much greater depth of working will be obtained. The coal is of prime quality; pure and durable in burning; firm, large, and of a ſtrong grain; which enſures its conveyance to almoſt any diſtance, without injury to its appearance or quality, which cannot be exceeded in any part of the kingdom. Bath is the principal market for ſale and place of conſumption; to which may be added, the weſtern parts of Wiltſhire, and the next adjacent parts of Somerſetſhire. The quantity raiſed is from fifteen hundred to two thouſand tons weekly: a much greater can be ſupplied, if an increaſed demand requires it. Men and boys, to the number of fifteen hundred, are employed in the workings, with wages ſufficiently adequate for a comfortable ſubſiſtence. The owners of the freehold whence the coal is raiſed generally receive an eighth of the groſs receipt of ſale. The average price of coal is five-pence *per* buſhel at the pit, nine gallon meaſure. The collieries in the ſouthern part of this diſtrict are on a more limited ſcale: the ſtrata of coal form an inclination of the plane from eighteen to thirty inches in the yard; in ſome the plane is annihilated, and the ſhafts deſcend in a perpendicular direction. The ſouth-weſtern parts of Wiltſhire, the northern diſtrict of Dorſetſhire, and the eaſt and ſouthern parts of Somerſetſhire, are the markets for conſumption. The quantity raiſed is from eight hundred to a thouſand tons weekly, and capable of extenſion. Men and boys are employed to the amount of from five to ſix hundred. Average price three-pence three farthings *per* buſhel. At Clapton, a village to the north-weſt of Leigh-Down, is a coal-work, which poſſeſſes the advantage of a land level of forty-four fathoms: about two hundred and forty buſhels are landed daily. The beſt coal is ſold at three-pence halfpenny *per* buſhel, and the ſmall is ſhipped at Portiſhead for Wales, where it is uſed for burning lime.

Rivers and Canals.—The principal rivers are the Avon, Ax, Brue, Parret, Yow, Cale, Chew, Tone, Frome, Ivel, Ex, and Barl. Of theſe, four only are navigable, *viz.* the Avon, from Bath to Briſtol, 16 miles; the Brue, from the Briſtol Channel to Highbridge, two miles; the Parret, from Stert-Point to Langport, about 20 miles; and the Tone, from Taunton to Boroughbridge, eight miles. The chief canals are, the Somerſetſhire coal canal, which has two branches, one commencing at Paulton, the other at Radſtock, and both communicating with that of the Kennet and Avon; the Dorſet and Somerſet canal, commencing near Nettlebridge, and extending to Frome and thence to the county of Dorſet; the Ilcheſter canal; the Grand Weſtern canal, extending 35 miles from Taunton into Dorſetſhire. For a particular account of theſe, ſee CANAL, in a former volume of this work.

Climate, &c.—Mr. Billingſley, who in the year 1795 drew up a general view of the agriculture of this county, divides it into three diſtricts, the north-eaſt, the middle, and the ſouth-weſt. The firſt comprehending the tract between the ports of Uphill and Kingroad on the weſt, and the towns of Bath and Frome on the eaſt; the ſecond embracing that portion which is bounded by the Mendip hills on the north, Bridgewater-bay on the weſt, and the town of Chard on the ſouth; the third occupying the remainder of the county. The north-eaſt diſtrict being very irregular in ſurface, and intermixed with lofty hills and rich fertile plains, the climate is in conſequence exceedingly varied. On the weſtern ſide, including the hundred of Winter-Stoke and Portbury, the ſoil is, for the moſt part, a deep and rich mixture of clay and ſand; being originally a depoſit by the ſea, which, in ancient times, flowed up a conſiderable way into that part of the country. Theſe moor-lands, as they are called, are ſubject to frequent inundation; and ſometimes in rainy ſeaſons are covered with water for four or five ſucceſſive months. The middle diſtrict of the county, which is the largeſt, poſſeſſes a climate, for the moſt part, mild and temperate; but on ſo varied a ſurface that uniformity of ſoil cannot be expected.

The ſouth-weſt diſtrict has nearly an equal portion of rough mountainous country, and rich fertile ſlopes and plains. The climate, particularly of that part which is called the Vale of Taunton-Dean, is peculiarly mild and ſerene, and the ſoil highly fertile and productive: and the eye is agreeably relieved by a judicious mixture of arable and paſture lands. There are, however, certain parts north-weſt of the vale which are mountainous, and ſubject to that mutability of weather, and moiſture of air, generally found on elevated ſituations.

Civil and Eccleſiaſtical Diviſions.—Somerſetſhire is divided into forty-three hundreds, and ſeven liberties. It contains two cities, Bath and Wells, with a part of Briſtol, ſeven boroughs, twenty-two market-towns, one biſhopric, three archdeaconries, thirteen deaneries, and four hundred and eighty-two pariſhes. Of the three archdeaconries, that of Bath contains two deaneries, Wells ſeven, and Taunton four.

Church Hiſtory.—Although the inhabitants of this county, as has been obſerved, embraced Chriſtianity in the ſeventh century, the eccleſiaſtical hiſtory commences only with the inſtallation of Athelm, a monk of Glaſtonbury, to the ſee of Wells, in the reign of Edward the Elder, in the early part of the tenth century. During this reign, pope Formoſus, for ſome unknown reaſon, excommunicated the whole kingdom, which continued under this ſentence ſeven years, by which ſeveral ſees were vacant; at length, the degraded monarch called a ſynod to conſider the ſtate of the church, and ſent archbiſhop Plegmund to procure the removal of the interdict, and have new biſhops confirmed. Having ſucceeded in his miſſion, ſeven biſhops were conſecrated in one day, among whom was Athelm, above-mentioned.

Political Economy.—Somerſetſhire is ſtated to contain 991,360 acres of land; of which 330,000 are arable, 534,500 paſture, 126,860 of commons, heaths, woods, waſtes, roads, &c. The population, according to the return to parliament in the year 1811, amounted to 303,180, of which 141,449 were males, 161,731 females; 23,732 families being ſtated to be employed in trade and manufactures, and 27,472 families chiefly in agriculture. The number of houſes were 54,787. The repreſentatives in parliament are, for the county, two; Bath, two; Bridgewater, two; Ilcheſter, two; Melborne-Port, two; Minehead, two; Taunton, two; Wells, two: in the whole ſixteen members. The county is included in the weſtern circuit; it is in the province of Canterbury; and in the dioceſe of Bath and Wells.—"The Hiſtory and Antiquities of the County of Somerſet," by Edm. Rack and the Rev. John Collinſon, 3 vols. 4to. 1791. "General View of the Agriculture of the County of Somerſet, by John Billingſley, eſq." 8vo. 1798.

SOMERSHAM, a conſiderable village and pariſh in the hundred of Hurſtingtone, and county of Huntingdon, England, is ſituated 6 miles diſtant from St. Ives, and 68 miles N. from London. It principally conſiſts of one ſtreet, about three-quarters of a mile in length from E. to W.; with a ſecond, but much ſhorter ſtreet, croſſing the former at right angles. The church is a ſpacious ſtructure, and conſiſts of a nave, chancel, and aiſles, with a ſubſtantial embattled tower at the weſt end. Near the church-yard is a free ſchool, with a large ſchool-houſe recently built, 54 feet in length. The rich rectory of Somerſham is annexed to the Regius profeſſorſhip of divinity at Cambridge, and now held by the venerable biſhop of Llandaff. Weever ſays, "William Weller (or Wolfere), parſon of Somerſham, was maſter of the rolls, ſerving Edward III. in the chancery, fortie years and more." The biſhops of Ely had formerly a palace here: the ſcite is now partly built on; but the adjacent grounds ſtill retain veſtiges of their ancient appropriation. The population of Somerſham, according to the return to parliament in the year 1811, was 1032; the number of houſes 152. A mineral ſpring was diſcovered here by the late Dr. Layard, who publiſhed a ſmall treatiſe concerning it in 1759, and whoſe experiments, with thoſe of Dr. Morris, on its waters, were printed in the fifty-ſixth volume of the Philoſophical Tranſactions: its virtues are now but little noticed.

About the year 1731, near the road leading from Somerſham to Chatteris, in a piece of fen-land belonging to William Thompſon, eſq. the plough turned up and broke a ſmall urn, containing ſeveral Roman coins: and Mr. Thompſon and the Rev. Mr. Ramſey, digging near the ſpot, found another, which contained about ſixty coins, moſtly copper, and of the late emperors. Camden's Britannia, by Gough, vol. ii. Beauties of England and Wales, vol. vii. by E. W. Brayley.

SOMERSWORTH, a townſhip of America, in Strafford county, New Hampſhire, taken from Dover, and incorporated in 1754, containing 878 inhabitants.

SOMERTON, a ſmall market-town in the hundred of the ſame name, Somerſetſhire, England, is ſituated near the centre of the county, to which it is ſaid to have originally given name, and is 125 miles W.S.W. from London. Somerton is ſaid to have been a Roman citadel: but we have no authentic account of it previous to the Heptarchy, when it appears to have been a town of conſiderable extent, and ſtrongly fortified. It was at one time a royal reſidence. Ina, and ſeveral other Weſt Saxon kings, held their courts here. In the year 877 it was plundered and laid waſte by the Danes, under the conduct of Inguar and Ubba; but was rebuilt, and recovered its importance, both for population and ſtrength. John, king of France, was confined in the caſtle of Somerton, after his removal from that of Hertford. In the time of Leland this caſtle was converted into a priſon: a part of the town-wall and a round tower ſtill remain, but in a very ruinous condition. The town now conſiſts principally of five ſtreets: it is governed by a bailiff and conſtables, elected annually by the inhabitants: a weekly market is held on Tueſdays, and four fairs annually. The church is an ancient ſtructure, conſiſting of a nave, chancel, and ſide-aiſles: at the ſouth end is an octangular embattled tower, 63 feet high. Near the church is an excellent free-ſchool; and a well-endowed alms-houſe for eight poor women. In the centre of the town is a hall for holding the petty ſeſſions. Adjoining to the town is the tything of Lower Somerton, or Somerton Erleigh; and about a mile eaſtward is the tything of Hurco: both are included in the pariſh; which, according to the population return of the year 1811, contained 338 houſes, and 1478 inhabitants. Collinſon's Hiſtory of Somerſetſhire, vol. iii.

SOMERVILLE, WILLIAM, in *Biography*, ſon of Robert Somerville, was born at his father's houſe at Edſton, in Warwickſhire. He was educated at Wincheſter ſchool, from which he was elected to New college, Oxford. Here he made a good proficiency in claſſical literature, and cultivated a talent for poetry. His firſt piece, as far as is known to the public, was an ode to the duke of Marlborough, on his diſmiſſion from his poſts in 1710. He was ſtrongly attached to the Whig party; and when Addiſon purchaſed an eſtate in Warwickſhire, Somerville addreſſed a poem to him, which includes the following couplet, alluding to the papers in the ſeveral volumes of the Spectator, to which are annexed the letters C, L, I, O.

"When panting virtue her laſt efforts made
You brought your CLIO to the Virgin's aid."

Mr. Somerville inherited a conſiderable paternal eſtate, on which he chiefly lived, acting as a magiſtrate, and purſuing with vigour the amuſements of a ſportſman, varied by the ſtudies of a man of letters. He was courteous and hoſpitable, but too much addicted to conviviality, and careleſs of economy. His mode of living threw him into embarraſſments, which ſo preyed on his mind, that for the ſake of relief, he fell into habits that ſhortened his life. He died in 1742, which Shenſtone thus notices to a friend and correſpondent.

"Our old friend Somerville is dead! I did not imagine I could have been ſo ſorry as I find myſelf on this occaſion. I can excuſe all his foibles, impute them to age and to diſtreſs of circumſtances: the laſt of theſe conſiderations wrings my very ſoul to think on. For a man of high ſpirit, conſcious of having, at leaſt in one production, generally pleaſed the world, to be plagued and threatened by wretches that are low in every ſenſe; to be forced to drink himſelf into pains of body, in order to get rid of pains of the mind, is a miſery."

Somerville is chiefly known, as a poet, by his piece entitled "The Chace," which is written in blank verſe, and which maintains a high rank in the didactic and deſcriptive claſs. It has the advantage of being compoſed by one who was perfectly acquainted with the ſports which are its ſubject, and who entered into them with all the enthuſiaſm which they are calculated to inſpire; hence his pictures, in exactneſs and animation, greatly excel the draughts of the ſame kind, attempted by poets by profeſſion. Its language is free and nervous, and its verſification generally denotes a nice and practiſed ear. He has another piece connected with this in ſubject; it is entitled "Field Sports," though it only deſcribes that of hawking. His "Hobbinol, or Rural Games," is a kind of mock heroic, in which the burleſque is managed with tolerable ſucceſs. Of his other pieces, ſerious and comic, there are few that can be ſaid to add to his fame; but they make a part of the collection of Britiſh Poets.

SOMEVOIRE, in *Geography*, a town of France, in the department of the Upper Marne; 15 miles S. of St. Dizier.

SOMGHETIA, a province in the principality of Georgia, W. of Teflis.

SOMINO, a town of Africa, in Bambarra, on the Niger. N. lat. 13° 11'. W. long. 4° 48'.

SOMLYO, a town of Hungary; 29 miles S. of Zatmar.

SOMMA, a town of Naples, in Lavora, near which are annually produced between 7000 and 8000 pounds of ſilk of the beſt quality; 10 miles E. of Naples.—Alſo, a town of Italy, in the department of the Olona; 24 miles N.W. of Milan.—Alſo, a town of the Popedom, in Umbria; 4 miles S. of Spoleto.

SOMMARIVA *del Boſco*, a town of France, in the department of the Tanaro; 5 miles S.E. of Carmagnola.

SOMMARIVA *di Perao*, a town of France, in the department of the Tanaro; 7 miles E.S.E. of Carmagnola.

SOMMARNAS, a town of Sweden, in the province of Tavaſtland; 35 miles S.S.W. of Tavaſthus.

SOMME, a river of France, which riſes near Fonſomme, in the department of the Aiſne, paſſes by or near to St. Quentin, Ham, Peronne, Bray, Corbie, Amiens, Pequigny, Abbeville, St. Valery, &c. and runs into the Engliſh Channel, about 5 miles W.N.W. of St. Valery.

SOMME, one of the eleven departments of the northern region of France, compoſed of Amienois, Ponthieu, Vimeux, and Santerre, between Calais and Oiſe, in N. lat. 49° 45′, and bounded on the N. by the department of the Straits of Calais, on the E. by the department of the Aiſne, on the S. by the department of the Oiſe, and on the W. by that of the Lower Seine, and the Engliſh Channel. Its territorial extent is 6512½ kiliometres, or in French leagues 34 in length, and 16 in breadth. It is divided into 5 circles or diſtricts, 41 cantons, and 848 communes. The circles are Abbeville, containing 114,060 inhabitants; Doullans, with 45,627; Peronne, with 91,470; Montdidier, with 62,668; and Amiens, with 151,209 inhabitants: the whole population being 465,034. According to M. Haſſenfratz, it is divided into 5 circles and 72 cantons; and its population conſiſts of 381,760 perſons. The capital is Amiens. In the year 11 of the French era, the amount of its contributions was 5,650,664 fr., and its expences and charges 395,027 fr. 69 cents. This department is fertile in grain, fruits, hemp, flax, and paſtures, and has ſome foreſts.

SOMMEIL, in *French Muſic*, an invocation to ſleep; an old French movement of the lullaby kind, much in favour during the time of Merſennus; and continued in uſe, according to Blainville, in the reign of Louis XIV., when operas were firſt attempted at Paris.

SOMMERDA, or SOMMERN, in *Geography*, a town of Saxony, in the territory of Erfurt; 11 miles N.N.E. of Erfurt.

SOMMERDYCK, or SOMMELSDYKE, or *Zomerdyck*, a town of Holland, and chief town of the iſland of Overflakee; 20 miles W.S.W. of Dort.

SOMMEREUX, a town of France, in the department of the Oiſe; 3 miles N.E. of Grandvilliers.

SOMMERFELD, a town of the New Mark of Brandenburg; 15 miles S. of Croſſen.

SOMMERGEM. See SOMERGEM.

SOMMERO, a ſmall iſland in the gulf of Finland. N. lat. 60° 8′. E. long. 24° 36′.

SOMMERSET. See SOMERSET.

SOMMERSHAUSEN, a town of Germany, in the lordſhip of Speckfeld, on the Maine; 4 miles S. of Wurzburg. N. lat. 49° 45′. E. long. 10° 3′.

SOMMIER, Fr. the wind-cheſt, or ſound-board of an organ. See SOUND-BOARD.

SOMMIERES, in *Geography*, a town of France, and principal place of a diſtrict, in the department of the Gard; 12 miles S.W. of Niſmes. N. lat. 43° 47′. E. long. 4° 11′.

SOMMITE, in *Mineralogy*, *Nepheline*, Haüy, a mineral which occurs in ſmall cryſtals and cryſtalline grains, in the lava on the ſides of mount Somma, a part of Veſuvius. The form of the cryſtal is a ſix-ſided priſm; the colour is greyiſh or greeniſh-white: the angles are ſufficiently hard to ſcratch glaſs. The cryſtals are lamellar on the faces of the priſm, but conchoidal, with a vitreous luſtre, in the direction perpendicular to the axis of the cryſtal. It melts with difficulty before the blow-pipe, into a tranſparent homogeneous glaſs. Its ſpecific gravity is 3.3. According to Vauquelin, ſommite contains

Silex - - - -	46
Alumine - - -	49
Lime - - - -	2
Oxyd of iron - -	1

This mineral covers the cavities of lava, and is accompanied with hornblende, mica, and veſuvian.

SOMNAMBULISM, in *Medicine*, from *ſomnus*, *ſleep*, and *ambulo*, *I walk*; ſometimes alſo called *noctambuliſm*, or *night-walking*; is a ſingular condition of the body, in which a perſon performs many voluntary actions, implying a certain degree of perception of the preſence of external objects, but without conſciouſneſs while the actions are performed, and without recollection of them when the conſciouſneſs returns.

This affection, as its name implies, is commonly conſidered as an imperfect degree of ſleep; as it moſt frequently occurs after ſleep, and ſeems to be but a more active exertion of volition than that which takes place in imperfect ſleep, when we move, and even talk, and ſupport ourſelves in different poſtures. "There are many caſes," ſays Mr. Stewart, "in which ſleep ſeems to be partial; that is, when the mind loſes its influence over ſome powers, and retains it over others. In the caſe of the *ſomnambuli*, it retains its power over the limbs, but it poſſeſſes no influence over its own thoughts, and ſcarcely any over the body; excepting thoſe particular members of it which are employed in walking." (See his Elements of the Philoſophy of the Human Mind, chap. 5, part i. § 5.) The ſubject is very obſcure, in conſequence perhaps of the rarity of theſe caſes, which have not been ſufficiently examined, ſince the phyſiology of the mind was rationally inveſtigated. Dr. Cleghorn, however, in his excellent theſis "De Somno" (Edin. 1783), pointed out ſome circumſtances which diſtinguiſh this condition from ſleep; and Dr. Darwin has more recently conſidered it as belonging to *reverie*, and not to ſleep, or as approximating rather to epilepſy or catalepſy, than to mere dreaming, or night-mare, to which it has alſo been referred.

Some of the moſt remarkable and beſt authenticated caſes of ſomnambuliſm on record ſeem to favour this view of the ſubject. The older authors, Horſt, Sennert, Schenck, Henry ab Heers, Willis, and many others, have related caſes of ſomnambuliſm, in which various actions were unconſciouſly performed, ſuch as opening doors and windows, croſſing bridges, even walking on the tops of houſes, and up precipitous paths, climbing to take a rook's neſt, and various other feats. It is ſaid, that if any ſenſation is excited ſufficiently ſtrong to awaken the ſomnambuli, they experience great ſurprize and terror, ſometimes fall in ſyncope, and have no recollection of what has paſſed during the paroxyſm. The eſſence of the diſeaſe, however, as Dr. Darwin obſerves, ſeems to "conſiſt in the inaptitude of the mind to attend to external ſtimuli;" and they are not eaſily awakened. One of the caſes moſt fully inveſtigated, and reported to the Phyſical Society of Lauſanne, while it exhibits the peculiarities of the malady, ſeems to prove that a ſlight and brief impreſſion is actually made upon the ſenſes, which excites afterwards ſo powerful a conception, or is ſo ſtrongly fixed in the imagination, that the volition continues to direct the actions as accurately as if the impreſſions on the ſenſes were repeated; which is alſo the character of reverie.

The ſomnambuliſt, in the caſe alluded to, was a lad thirteen years and a half old, of a good conſtitution, but of great ſenſibility and irritability, and very variable ſpirits.

His proceedings were watched by a committee of gentlemen, who reported the reſult to the ſociety above-mentioned. His ſleep was at all times unquiet, but the walking did not occur every night; ſometimes ſeveral weeks paſt, during which he was free from it. The paroxyſm commonly began about three or four o'clock in the morning, and the longeſt of them laſted from three to four hours. It was preceded by motions in every part of the body, with ſtarting and palpitations: he then uttered broken words, and ſometimes ſat up in his bed, and afterwards lay down again. Then he began to pronounce words more diſtinctly, roſe abruptly, and acted according to the inſtigation of his imagination. When he came out of the paroxyſm, he did not recollect any of the actions he had been performing. It was dangerous, however, to awaken him during the continuance of it, eſpecially if it were done ſuddenly; for he ſometimes fell into convulſions. "Having riſen one night with the intention of going to eat grapes, he left the houſe, paſſed through the town, and went to a vineyard, where he expected good cheer. He was followed by ſeveral perſons, who kept at ſome diſtance from him, one of whom fired a piſtol, the noiſe of which inſtantly awakened him, and he fell down without ſenſe. He was carried home and brought to himſelf, when he recollected very well having been awakened in the vineyard, but nothing more, except the fright at being found in the vineyard alone, which had made him ſwoon."

The following ſtatements ſhew how the impreſſions of external objects on the ſenſes mingled with his reverie, as in the caſe of ordinary dreams. See DREAMS.

"Once he was obſerved dreſſing himſelf in perfect darkneſs. His clothes were on a large table, mixed with thoſe of ſome other perſons; he immediately perceived this, and complained of it much: at laſt a ſmall light was brought, and then he dreſſed himſelf with ſufficient preciſion. While his imagination was employed on various ſubjects, he heard a clock ſtrike, which repeated at every ſtroke the note of the cuckoo. 'There are cuckoos here,' ſaid he; and, upon being deſired, he imitated the ſong of that bird immediately." Again, the reporters ſay, "If he is teazed, or gently pinched, he is always ſenſible of it (unleſs he is at the time ſtrongly impreſſed with ſome other thing), and wiſhes to ſtrike the offender: however, he never attacks the perſon who has done the ill, but an ideal being, whom his imagination preſents to him, and whom he purſues through the chamber without running againſt the furniture, nor can the perſons whom he meets in his way divert him from the purſuit."

Other facts, which the reporters record, impreſſed them with a belief that the ſleep-walker was capable of receiving certain impreſſions through the medium of the ſenſes, when they accorded with the images which his imagination was occupied in forming; but that this faculty was predominant, and only admitted thoſe perceptions which, on the principles of aſſociation, mingled with the reverie. They inferred, too, that he was obliged to open his eyes, in order to recognize objects; but that the impreſſion, once made, although rapidly, was vivid enough to ſuperſede the neceſſity of opening them again; that is, the ſame objects appeared to be afterwards repreſented by the conceptions of his imagination, with as much force and preciſion, as if he actually ſaw them. In the effort to open his eyes, however, when he wiſhed to ſee an object, he could ſcarcely raiſe them a line or two, by drawing up his brows; and the iris appeared fixed, and the eye dim. He made this effort whenever any thing was preſented to him, and he was told of it, always half opening his eyes with great difficulty, and then ſhutting them after he had taken what was offered.

"Having engaged him to write a theme," the committee obſerve, "we ſaw him light a candle, take pen, ink, and paper from the drawer of his table, and begin to write, while his maſter dictated. As he was writing, we put a thick paper before his eyes, notwithſtanding which he continued to write, and to form his letters very diſtinctly; ſhewing ſigns, however, that ſomething incommoded him, which apparently proceeded from the obſtruction which the paper gave to his reſpiration, being held too near his noſe."

"An experiment was made by changing the place of the ink-ſtandiſh, while Devaud was writing. He had a light beſide him, and had certified himſelf of the place where his inkholder was ſtanding by means of ſight. From that time he continued to take ink with preciſion, without being obliged to open his eyes again: but the ink-ſtandiſh being removed, his hand returned as uſual to the place where he thought it was. It muſt be obſerved, that the motion of his hand was rapid, till it reached the height of the ſtandiſh, and then he moved it ſlowly, till the pen gently touched the table, as he was ſeeking for the ink. He then perceived that a trick had been put upon him, and complained of it: he went in ſearch of his ink-ſtandiſh, and put it in its place."

This experiment, they affirm, was ſeveral times repeated, and was always attended with the ſame circumſtances. And they put the following queſtions reſpecting the inferences to be drawn from it. "Does not what we have here ſtated prove, that the ſtandiſh, the paper, the table, &c. are painted on his imagination in as lively a manner as if he really ſaw them; ſince he ſought the real ſtandiſh in the place where his imagination told him it ought to have been? Does it not prove that the ſame lively imagination is the cauſe of the moſt ſingular actions of this ſleep-walker? And, laſtly, does it not prove that a mere glance of his eye is ſufficient to make his impreſſions as lively as durable?"

Theſe concluſions appear to be legitimate; and the facts ſeem to ſhew how much more completely this condition of the ſomnambuliſt is allied to *reverie*, than to *ſleep*, though commonly commencing from the latter. From the ſlighteſt degree of abſence, or *brown* ſtudy, as it is popularly called, in which the conceptions of the imagination, upon ſubjects that intereſt the individual, are ſo vivid as to exclude for a time the perceptions excited by ſurrounding objects, up to this complete ſomnambuliſm, various degrees of the abſtraction from external impreſſions may be traced. Moſt perſons, perhaps, have been ſenſible, at times, when any ſubject of ſevere ſtudy, or any great gratification, anxiety, or diſtreſs ſtrongly occupied their minds, how great the diſpoſition to this abſtraction has been. If engaged in reading, they have purſued every line with the eye, turned over leaf after leaf, and at length awoke from the reverie which had occupied the imagination, and found that not the ſmalleſt impreſſion had been made on the mind by the pages which the eye had peruſed, and the hand had turned over. If walking in a crowded ſtreet, they have probably proceeded ſome way under the influence of reverie, moving the limbs as uſual, directing the walking-ſtick, and performing other unconſcious but voluntary acts, winding ſafely among the paſſing people, avoiding the poſts and other obſtacles, but ſo excluſively occupied by the conceptions of the mind, as to be totally inſenſible of all theſe actions of their own volition, and of the objects which they have paſſed, and which neceſſarily impreſs their ſenſes ſo as to regulate thoſe acts. From this ſtate of the faculties in reverie, which we have ſo often experienced in ourſelves,

ſelves, and obſerved in others, as to ſuppoſe that the truth of the foregoing ſtatement will be readily admitted, that condition of them which conſtitutes ſomnambuliſm ſeems to differ principally in two circumſtances, *viz.* in commencing commonly in a diſturbed ſleep, and in requiring a ſtronger impreſſion upon the ſenſes to break the chain of mental conception; ſo that the lighter impreſſions only mingle with and modify the conceptions, according to the principle of aſſociation. The following ſingular example of the ſomnambuliſtic reverie is well authenticated, and is related of an amiable and diſtinguiſhed poet. We quote it from the life of that writer in Anderſon's edition of the poets, vol. xi.

"Dr. Blacklock, one day, haraſſed by the cenſures of the populace, whereby not only his reputation, but his very ſubſiſtence was endangered, and fatigued with mental exertion, fell aſleep after dinner. Some hours after, he was viſited by a friend, anſwered his ſalutation, roſe, and went with him into the dining-room, where ſome of his companions were met. He joined with two of them in a concert, ſinging, as uſual, with taſte and elegance, without miſſing a note, or forgetting a word. He then went to ſupper, and drank a glaſs or two of wine. His friends, however, obſerved him to be a little abſent and inattentive: by and by he began to ſpeak to himſelf, but in ſo ſlow and confuſed a manner, as to be unintelligible. At laſt, being more forcibly rouſed, he awoke with a certain ſtart, unconſcious of all that had happened; as till then he had continued faſt aſleep."

Thoſe who wiſh to inveſtigate this curious ſubject farther, may conſult the old writers mentioned in the beginning of this article; alſo Hoffmann's Diſſertatio de Somnambuliſmo, in the third volume of the ſupplement to his works; the French Encyclopédie, article *Somnambuliſme;* Darwin's Zoonomia, vol. i. ſect. xix; Cleghorn de Somno, &c.

SOMNER, William, in *Biography*, an able antiquary, was born at Canterbury in the year 1606. He received a good common education, after which he was taken as clerk by his father, who was regiſter of the court of Canterbury. He was afterwards promoted by archbiſhop Laud to an office in the eccleſiaſtical court of that dioceſe, which naturally engaged him in the ſtudy of national antiquities. To purſue this to advantage, he applied with great diligence to the Saxon tongue, and having made himſelf maſter of that language, he drew up copious notes, and a gloſſary, to ſir Roger Twiſden's publication of the laws of Henry I. The antiquities of his own country engaged his particular attention, and he compoſed "A Treatiſe of the Roman Poſts and Forts in Kent," left by himſelf in MS. but which was printed at Oxford in 1693; and "A Treatiſe on Gavelkind," completed in 1647, and publiſhed in 1660. He alſo wrote "A Diſcourſe of Portus Iccius," which was afterwards tranſlated into Latin by biſhop Gibſon, and publiſhed with ſome other tracts. Having ſtudied all the kindred dialects to the Saxon, he wrote obſervations on ſome old German words, collected by Lipſius, which were publiſhed by Meric Caſaubon, and he drew up the Gloſſary annexed to the ten writers of Engliſh hiſtory, publiſhed by Twiſden. This gloſſary being a key to recluſe and antiquated words, improved whatever of this nature had been done before. It is, indeed, a work of that extent as may ſerve as a key to all other hiſtorians, and to all records: "nevertheleſs," ſays the writer of the life in the Biographia Britannica, "it might be greatly improved from our author's ſubſequent collections, which remain in the archives of Canterbury; from Junius's "Etymologicum Anglicanum;" and from Dr. Wilkin's Gloſſary, at the end of his edition of the Saxon laws. Mr. Somner aſſiſted Dugdale in compiling the "Monaſticon." In 1659 he publiſhed a Saxon dictionary, in folio, which has been ſtyled the true and laſting monument of his praiſe; a work of incredible labour to himſelf, and of ſingular benefit to the world. The previous aſſiſtance of the like kind which came into Mr. Somner's hands were, 1. Ælfric's Gloſſary, tranſcribed by Fr. Junius, from a very ancient copy in the library of ſir Peter Paul Rubens, of Bruſſels; 2. The two ancient gloſſaries in the Cotton library; 3. Nowell's Saxon Vocabulary; 4. Joceline's Collections. From theſe and ſome other Saxon books then extant, Mr. Somner made immenſe collections, in two large volumes, for the compiling his dictionary. When it was finiſhed, he ſent it to Oxford, where it was printed, and it came out in the year already mentioned. During the compoſition of this dictionary, he was chiefly ſupported by the ſalary ſettled on the Saxon lecture, founded by ſir Henry Spelman. Somner being a zealous royaliſt, he was arreſted and impriſoned on account of the Kentiſh petition for a free parliament, in the ſame year that his dictionary was publiſhed; but was liberated on the reſtoration, and promoted to the maſterſhip of St. John's hoſpital, in Canterbury. He died in 1669, and his books and manuſcripts were purchaſed by the dean and chapter of Canterbury, and depoſited in the cathedral library. Biog. Brit.

SOMNIFEROUS. See Soporiferous.

SOMNOLENTUM Coma. See Coma.

SOMNUS, in *Mythology*. See Sleep.

SOMORROSTROW, in *Geography*, a town of Spain, in the province of Biſcay, ſituated on a bay of the Atlantic; which, according to the opinion of baron Dillon, has all the appearance of being alluvial. Some of the workmen, as he ſays, aſſured him that they have often found broken pieces of pick-axes, mattocks, and other inſtruments, in places that had been worked centuries ago, and are now replete with new ore. Hence he infers that the mine increaſes. The ore is ſaid to form an uninterrupted ſtratum, whoſe thickneſs varies from three to ten feet, and is covered with a coat of whitiſh calcareous rock, from two to ſix feet thick. Every one is at liberty to dig at pleaſure, and tranſport it by land or water, without being ſubject to duties or any formalities. It is generally allowed, that no iron in Europe is ſo eaſy to fuſe, or ſo ſoft, as that of Somorroſtrow. When the ore is firſt taken out of this mine, it has the colour of bull's blood; and when wetted becomes purple. Great quantities are carried away by water to the neighbouring provinces, where they fuſe it by itſelf, or mix it with ore of their own, which generally yields a harder iron. According to appearance, a quintal of ore will produce about 35 lbs. of good iron, and the reſidue about 30 lbs. of ſlag and dead earth. 13 miles N.W. of Bilbao. N. lat. 43° 19′. W. long. 3° 7′.

SOMOSIERRA, a town of Spain, in New Caſtile; 8 miles N. of Buytrago.

SOMOVNIA, a town of European Turkey, in Bulgaria; 10 miles W. of Nicopoli.

SOMPIL, a town of Thibet; 45 miles E.S.E. of Pa.

SOMPUINS, or Sompy, a town of France, in the department of the Marne, and chief place of a canton, in the diſtrict of Vitry-ſur-Marne; 18 miles N.W. of Menehould. The place contains 645, and the canton 4745 inhabitants, on a territory of 382½ kiliometres, in 16 communes.

SOMSDORF, a town of Saxony, in the circle of Erzgebirg; 10 miles S. of Freyberg.

SON, a relative term, applied to a male child, conſidered in the relation he bears to his parents. See Child and Parent.

The children of the king of England are called *ſons* and *daughters* of *England.* The eldeſt ſon is born duke of Cornwall, and created prince of Wales. The younger ſons are called *cadets.*

The king of France's children were anciently called *fils* and *filles de France, ſons* and *daughters of France;* and the grand-children, *petits fils* and *petits filles de France.* At a later period, the daughters were called *meſdames;* and the grand-daughters *meſdemoiſelles de France.*

Son, *Natural.* See Bastard.

Son, *Adoptive.* See Adoptive.

Son *of God,* is a term uſed in various ſenſes in the holy ſcripture, as, 1. For Jeſus Chriſt, or the Saviour of mankind; who is thus called, as ſome ſay, with reſpect to the manner of his generation, as being begotten of the Father.

This ſeems to have been the opinion of Dr. Clark, in his "Scripture Doctrine of the Trinity." Generation, ſays he, when applied to God, is but a figurative word, ſignifying only, in general, immediate derivation of being and life from God himſelf: and "only begotten" ſignifies being ſo derived from the Father, in a ſingular and inconceivable manner, as thereby to be diſtinguiſhed from all other beings. Among men, a ſon does not, properly ſpeaking, derive his being from his father; father, in this ſenſe, ſignifying merely an inſtrumental, not an efficient, cauſe: but God, when he is ſtyled father, muſt neceſſarily be underſtood to be (*αιτια*) a true and proper cauſe, really and efficiently giving life. This conſideration, he ſays, clearly removes the argument uſually drawn from the equality between a father and ſon upon earth. It is obſervable, as our author proceeds, that St. John, in that paſſage, where he not only ſpeaks of the Word before his incarnation, but carries his account of him farther back than any other place in the whole New Teſtament, gives not the leaſt hint of the metaphyſical manner how he derived his being from the Father; does not ſay, he was created, or emitted, or begotten, or was an emanation from him, but only that he *was,* that he *was in the beginning,* that he *was with God,* and that he was (Θεος) partaker of divine power and glory with and from the Father, not only before he was *made fleſh* or *became man,* but alſo *before the world was.* As the ſcripture, ſays Dr. Clark, has no where diſtinctly declared in what particular metaphyſical manner the Son derives his being from the Father, men ought not to preſume to be able to define.

Some ſuppoſe, that this title of "ſon of God" belongs to Chriſt, on account of his poſſeſſing the ſame divine nature with the Father. Accordingly biſhop Pearſon ſays, the communication of the divine eſſence by the Father was the true and proper generation, by which he hath begotten a ſon. A ſon is nothing but another produced by his father, of the ſame nature with him. But God the Father hath communicated to the Word the ſame divine eſſence, by which he is God; and he ſays, the Father hath the eſſence or attributes of himſelf, and the Son by communication from the Father. But Dr. Waterland denies any literal generation of the ſon at all; for he ſuppoſes his being in the Father, before he was generated, to be the firſt and moſt proper filiation or generation; which he allows to be a mere co-exiſtence with the Father, and not any derivation from him.

Whilſt the Athanaſians believed the Father and Son to be of the ſame ſubſtance, *i. e.* of the ſame *generical* ſubſtance, as two men are of the ſame ſubſtance; and the Pſeudo-Athanaſians believed them to be of the ſame identical *numerical* ſubſtance; the Arians, who believed the divine ſubſtance of the Father to be αγεννητος, unbegotten, and αναρχος, without beginning, concluded, that it was different from the ſubſtance of the Son, who was begotten, and had a beginning. Moreover, as they believed the divine ſubſtance of the Father to be indiviſible and uncompounded, they could not believe the Son to be generated in or from it, in any *literal* ſenſe, either as being compounded with it, or divided from it; and, therefore, they concluded, that the generation of the Son was *figurative,* and was not a participation of ſubſtance, but a creation; as the word creation is frequently uſed in ſcripture with regard to mankind. They believed that Chriſt was the only begotten Son of God, becauſe he only was created by the immediate act and power of God himſelf, and that all other beings, the Holy Ghoſt not excepted, were created by Chriſt; in which they agreed with Origen and Euſebius; and, therefore, they called him a creature, but not like other creatures; but they believed that he was generated or created before all ages.

Sonſhip, ſays Dr. Lardner, in his "Letter on the Logos," (Works, vol. x. vol. xi.) is a term of nearneſs, dearneſs, and affection; and Jeſus is the Son of God, 1ſt, upon account of his miraculous conception and birth (Luke, i. 31—35); 2dly, upon account of the eſpecial commiſſion given him by the Father, and the extraordinary qualifications beſtowed upon him, in order to his fulfilling it (Matt. iii. 16. Mark, i. 10. Luke, iii. 21, 22. John, i. 32—34. iii. 34. Iſ. xi. 1—3. xlii. 1—4. lxi. 1—3. and Matt. xii. 17. Luke, iv. 18, 19.); 3dly, on account of his reſurrection from the dead on the third day, to die no more (Rom. i. 3, 4. Heb. i. 6.); 4thly, on account of his exaltation to God's right hand, and being inveſted with authority and dominion over all fleſh, and conſtituted judge of the world, by whom God will paſs ſentence upon all mankind (John, iii. 35. v. 21, 22. Heb. i. 1, 2. iii. 5, 6.); 5thly, on account of the pouring out of abundance of ſpiritual gifts, though in different degrees, upon his apoſtles, and thoſe who believed in him after his reſurrection (John, i. 32—34. Matt. iii. 1. Mark, i. 8. Luke, iii. 16. John, vii. 37—39. Acts, xi. 15, 16. i. 5. ii. 1—36. Gal. iv. 6. Eph. ix. 8—13.) Upon all theſe accounts, and not only upon account of his miraculous conception and birth, is Jeſus "the Son of God." Our author ſuggeſts, that the paſſages which he has cited manifeſtly ſhew, that it is in reſpect to his humanity, and the dignity conferred upon it, that he has the title of the Son of God. This learned author rejects the opinion of thoſe who underſtand by the "Son of God," an intelligent being or emanation, begotten by the Father, or proceeding from him, in an ineffable manner, from all eternity, and of the ſame eſſence or ſubſtance with the Father; and alſo of others, who underſtand by this appellation a mighty ſpirit, or angel, begotten or formed by the will of the Father, in time, before the creation of the world, and of a different ſubſtance from the Father; which ſon of God, as they ſay, became incarnate, that is, united himſelf, either to the human nature, conſiſting of ſoul and body, or to an human body, ſo as to ſupply the place of a human ſoul. Theſe ſenſes of the title, as he ſays, are not to be found in any of the books of the New Teſtament. The Jews, according to Whitby upon Rom. ix. 5. had no notion that their Meſſiah ſhould be any thing more than mere man. See alſo Jortin's Diſcourſes concerning the Chriſtian Religion, p. 17. In the goſpels, as Dr. Lardner obſerves, this title of the "Son of God" is given to our Lord, by many who took him to be a man ſpecially favoured by God. (Matt. xvi. 16. and the parallel places. John, vi. 69. John, i. 34. iii. 35, 36. John, i. 49. xi. 27. Matt. xiv. 33. Luke, iv. 41.) Our bleſſed Lord likewiſe often takes it to himſelf, either directly or indirectly. (John, iii. 17, 18, v. 25. ix. 35—37. x. 36. xi. 4.) In the Jewiſh ſtyle, and the language of ſcripture, all good men, and all people who are in a covenant relation to God, are his ſons, and as ſuch entitled to many privileges and bleſſings; but Jeſus, as the Meſſiah, is "the Son of God," by way of eminence and diſtinction, and has in all things the pre-eminence. Accordingly, the Chriſt, or the Meſſiah, and the "Son of God," are equivalent in the New Teſtament. (Matt. xvi. 16. John, vi. 69. Mark, viii. 19. Luke, ix. 20.) And that, in the language of the Jews, the titles of Meſſiah and Son of God are the ſame, may be ſeen in Matt. xxvi. 63. and Luke, xxii. 66. 70. John, i. 34—49.

2. Several creatures are alſo called "ſons of God," not as being ſo by nature and generation, but on divers other accounts. Thus, the angels are called ſons of God by Job, in reſpect to their creation, adoption, &c. And great men are called ſons of God in the Pſalms, as being his lieutenants, or the depoſitories of his authority. Good men, and particularly the eminently pious, as we have clearly ſhewn, are alſo called ſons of God, in various places of the ſacred writings.

Son *of Man*, is frequently uſed, in ſcripture, to ſignify man; as expreſſing not only the nature of man, but his frailty.

The expreſſion is very uſual among the Hebrews and Chaldeans: Daniel, Ezekiel, and Jeſus Chriſt, are particularly thus called; the firſt once, and the two latter frequently.

Some think, that the "ſon of man," when uſed by our Saviour, denotes his high dignity, or a man of diſtinction and eminence, and is equivalent to Meſſiah, or the Chriſt; and he thus intends to ſignify, that he is the great perſon ſpoken of by the prophets, who was to come for the benefit of mankind. (See Dan. vii. 13, 14. Matt. xxvi. 63, 64. Mark, xiv. 61, 62.) Againſt this ſenſe Dr. Lardner has ſuggeſted ſome exceptions: and he obſerves, that man, and ſon of man, with the Hebrews, often denote a man of low condition. (Pſ. xlix. 1, 2. Pſ. cxliv. 3.) Our Lord, therefore, by this phraſe or character, might repreſent that humbling of himſelf, which is ſpoken of by the apoſtle in the ſecond chapter to the Philippians, and is the ſame with what is ſaid in Iſ. liii. 3. "he is deſpiſed, and rejected of men," or is one of the loweſt and meaneſt of men. Our Lord adopts this character in ſpeaking of himſelf, in order to undeceive the Jews, and correct their falſe opinion concerning the kingdom of the Meſſiah; and to intimate, that he was not to arrive at glory, and the full poſſeſſion of his kingdom, but through ſufferings and humiliations. If ſon of man, then, be equivalent to Meſſiah, it is not uſed, as our author conceives, to denote his dignity, as the firſt and greateſt of men, but rather to ſignify his humble form and low condition, in which he then lived; and is expreſſive of the ſcorn and contempt which were caſt upon him, and in which he acquieſced.

Dr. Lardner further intimates, agreeably to his own opinion of the perſon of Chriſt, that he frequently makes uſe of this expreſſion to denote his real humanity, and alſo that he was not made and created as Adam, but was a man born even of a woman. He adds alſo, that our Lord might aſſume this character as a modeſt way of ſpeaking. Eminent and diſtinguiſhed perſons, who have many occaſions to ſpeak of themſelves, eſpecially if it be to their advantage, decline the too frequent uſe of the phraſes *I* and *me*, and chooſe to ſpeak in the third perſon, as of another, diſtinct from themſelves. Works, vol. x.

Sometimes the phraſe ſon of man is alſo uſed for the wicked and reprobate; in contradiſtinction to thoſe called ſons of God.

Son, Fr., a muſical ſound.

Son *Fondamental.* See Fundamental.

Son *Fix*, Fr., a fixed and unalterable ſound. To acquire ſuch a ſound, we muſt be certain that it will be the ſame at all times, and in all places. To be ſure of this, it is not ſufficient to have a pipe of a certain length or diameter in the fixed place; for though the pipe may always remain in the ſame ſtate, the weight of the air will not always remain the ſame: the ſound will become more grave or acute, as the air becomes more denſe or rarefied. For the ſame reaſon, the ſound of the ſame pipe will change with the column of the atmoſphere, in proportion as this pipe ſhall be carried high or low, in the mountains or in the villages.

Secondly, this ſame pipe, of whatever materials it is made, will be ſubject to the variations which heat and cold occaſion in all bodies. A pipe or ſtring, if of metal, will lengthen or ſhorten; and its tone will be higher or lower, in proportion. If the pipe be of wood, it will ſwell or ſhrink, expand or contract; and from theſe cauſes combined, ariſes the difficulty of acquiring a fixed tone, and almoſt the impoſſibility of being ſure of the ſame ſound in two places at the ſame time, or twice in the ſame place.

Son, or *Sun-Plant*, the *crotalaria juncea* of Linnæus, in *Botany*, is cultivated in every part of Hindooſtan with great aſſiduity, and applied to various uſes. The ſeeds reduced to powder, and mixed with oil, form a kind of unguent, which the black ladies apply to their hair, in order to make it grow. The bark of this plant furniſhes all kinds of rope, packing-cloths, nets, &c.; and from theſe, when old, moſt of the paper in that country is prepared. For this purpoſe they cut them into ſmall pieces, macerate them in water for about five days, waſh them in water, and then throw them into a veſſel of water ſtrongly impregnated with a lixivium compoſed of ſix parts of ſedgi mutti, which is an earth containing a large portion of foſſile alkali, and ſuppoſed to be the natron of the ancients, and ſeven parts of quick-lime. Here they remain eight or ten days, when they are again waſhed, broken into fibres by a ſtamping lever, and then expoſed to the ſun, and again ſteeped in a freſh lixivium, as before. When they have undergone three operations of this kind, they are fit for making coarſe brown paper; and after ſeven or eight operations, they are prepared for making paper of a tolerable whiteneſs. For a farther account of the proceſs, ſee Phil. Tranſ. vol. lxiv. p. 101, where it is minutely deſcribed and illuſtrated by figures.

SONABARYA, in *Geography*, a town of Bengal; 38 miles N.E. of Calcutta.

SONAH, a town of Hindooſtan, in Bengal; 8 miles S.S.E. of Ghidore.

SONAN Sundi, a town of Congo; 10 miles W. of Cundi.

SONAPURRA, a town of Hindooſtan, in Bengal; 26 miles E.S.E. of Kiſhenagur.

SONATA, Ital. from *ſuonare, to ſound*, or play on an inſtrument. Its uſe at preſent, in *Muſic*, is confined to ſolos for a ſingle inſtrument: as Corelli's ſolos for the violin, Martini's ſolos for the German flute; and trios, or compoſitions in three parts, for two violins and a baſe, &c. But which, in the body of theſe works, are all called *ſonatas*.

In the laſt and 17th century, the Italians had diſtinct ſonatas of two kinds: as *ſonate da chieſa*, ſonatas for the church; and *ſonate da camera*, ſonatas for the chamber, or private concerts, of a lighter kind. The firſt and third ſet of Corelli's ſonatas are of the former kind, and the ſecond and fourth of the latter. To the firſt and third ſet of Corelli's ſonatas for the church, there are two baſes, one for the baſe viol, or viol da gamba, and the other for the organ, arch lute or harp, figured for thorough-baſe.

In vocal muſic, *ſi ſuona* is written over the ſymphony or ritornelli, interſtitial paſſages played by an inſtrument, either as an echo to the voice part, or to give the ſinger time to breathe. *Si canta*, "it is ſung," to diſtinguiſh the vocal from the inſtrumental paſſages of ſongs written on one ſtaff.

SONAUT, or SUNAT *Rupee*, in *Commerce*. See RUPEE.

SONAWRY, in *Geography*, a town of Hindooſtan, in Oude; 20 miles S. of Bahraitch.

SONAX, a town of France, in the department of Mont Blanc; 4 miles N.N.E. of Chambery.

SONCHUS, in *Botany*, σογχος of Dioſcorides, ſuppoſed by ſome etymologiſts to be corrupted from σομφος, *hollow*, or *empty*, in alluſion to its hollow ſtem. This ſeems ſcarcely ſatisfactory, and yet we meet with nothing elſe worth mentioning. In Engliſh it is named Sow-thiſtle, becauſe ſwine are particularly fond of the plant.—Linn. Gen. 400. Schreb. 527. Willd. Sp. Pl. v. 3. 1509. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 436. Sm. Fl. Brit. 815. Prodr. Fl. Græc. Sibth. v. 2. 124. Purſh 501. Juſſ. 169. Tourn. t. 268. Lamarck Illuſtr. t. 649. Gærtn. t. 158.—Claſs and order, *Syngeneſia Polygamia-æqualis*. Nat. Ord. *Compoſitæ ſemifloſculoſæ*, Linn. *Cichoraceæ*, Juſſ.

Gen. Ch. *Common Calyx* imbricated, bellying, of numerous, linear, unequal ſcales. *Cor.* compound, imbricated, uniform; florets all perfect, numerous, equal, of one petal, ligulate, linear, abrupt, with five teeth. *Stam.* Filaments five, capillary, very ſhort; anthers united into a cylindrical tube. *Piſt.* Germen nearly ovate; ſtyle thread-ſhaped, the length of the ſtamens; ſtigmas two, reflexed. *Peric.* none, except the calyx, cloſing into the form of a depreſſed globe, with a conical point. *Seeds* ſolitary, rather oblong; down capillary, ſeſſile. *Recept.* naked.

Eſſ. Ch. Receptacle naked. Calyx imbricated, ſwelling at the baſe. Seed-down ſimple, ſeſſile.

Having detailed at length the ſpecies of SCORZONERA, (ſee that article,) a genus which has been, in ſeveral inſtances, confounded with the preſent, we find it neceſſary to give a reformed view of *Sonchus*, following Willdenow in the diſtribution of the ſpecies.

1. S. *maritimus*. Sea Sow-thiſtle. Linn. Sp. Pl. 1116. Willd. n. 1. Ait. n. 1. Prodr. Fl. Græc. n. 1889. Allion. Pedem. v. 223. t. 16. f. 2. Cavan. Ic. v. 1. 38. t. 51.—Flower-ſtalks moſtly ſolitary, terminal, naked. Leaves claſping the ſtem, lanceolate, undivided, with ſharp reflexed teeth.—Native of maritime ſituations in the ſouth of Europe, and north of Africa. Dr. Sibthorp met with it in Crete. Miller cultivated this plant in 1748, but it is hardly to be ſeen in any garden at preſent, either here or on the continent. The *root* is perennial. *Stem* herbaceous, about two feet high, ſlender, round, ſcarcely divided. *Leaves* near a foot long, narrow, ſmooth, glaucous, with a double ſet of ſmall, ſharp, recurved teeth; their baſe tapering, entire, claſping the ſtem at the bottom. *Flowers* ſometimes two or three, on long, ſlightly bracteated, ſtalks, yellow, above an inch in diameter, with a ſmooth *calyx*.

2. S. *craſſifolius*. Thick-leaved Sow-thiſtle. Willd. n. 2. Pourret MSS.—"Flower-ſtalks ſomewhat umbellate, ſcaly. Leaves lanceolate, with ſpreading pointed teeth; their baſe rounded, claſping the ſtem."—Native of Spain. *Root* perennial. This plant is intermediate between *S. maritimus* and *arvenſis*, but moſt akin to the former. *Stem* ſimple, erect. *Leaves* thick and glaucous, unequally toothed; the teeth lanceolate, ſpreading at right angles. *Flowers* the ſize of the preceding, terminal, ſomewhat umbellate, with very ſhort, ſolitary, ſingle-flowered, axillary ſtalks, from the uppermoſt leaves. Each *ſtalk* is ſcaly, and ſhorter than its *calyx*.

3. S. *uliginoſus*. Bog Sow-thiſtle. "Marſchall von Bieberſtein." Fiſcher MSS.—Flower-ſtalks ſomewhat umbellate, naked, much longer than the calyx. Leaves elliptic-oblong, with copious, ſpreading, pointed teeth; their baſe rounded, claſping the ſtem.—Native of mount Caucaſus. Communicated under the above name, by Dr. Fiſcher of Moſcow. This ſeems nearly related to the laſt. The *ſtem* is erect, ſtout, ſomewhat branched, three feet or more in height, round, ſmooth, leafy. *Leaves* four or five inches long, and above an inch broad, acute, ſmooth, veiny, rather thick or coriaceous, ſlightly glaucous, bordered with very numerous ſpinous teeth, projecting at right angles. *Flowers* reſembling the laſt, four or five together in terminal umbels, whoſe ſtalks are quite naked and ſmooth, as well as the *calyx*.

4. S. *quercifolius*. Oak-leaved Shrubby Sow-thiſtle. Desfont. Atlant. v. 2. 225. t. 213. Willd. n. 3.—Flower-ſtalks ſomewhat corymboſe, alternate, ſlightly ſcaly. Calyx-ſcales looſely imbricated. Leaves oblong, ſinuated, toothed, ſomewhat three-pointed. Stem ſhrubby. On hills near Cafsa in Barbary. *Stem* from one to two feet high, branched, thick and fleſhy. *Leaves* ſcattered, from four to eight inches long, very ſmooth and glaucous, rather ſucculent, evergreen, pinnatifid, with ſharp lobes, directed forward rather than backward, their baſe tapering down into a ſhort dilated *footſtalk*. *Flowers* terminal, yellow, about an inch and a half broad, four or five together in a lax corymboſe panicle. Scales of the *calyx* ovate, ſmooth, not cloſe-preſſed. *Desfontaines*.

5. S. *fruticoſus*. Great Shrubby Sow-thiſtle. Linn. Suppl. 346. Willd. n. 4. Ait. n. 2. Jacq. Coll. v. 1. 83. Ic. Rar. t. 161. L'Herit. Stirp. t. 81.—Flower-ſtalks ſomewhat umbellate, bracteated. Calyx-ſcales looſely imbricated. Leaves oblong, ſinuated, ſlightly runcinated, toothed. Stem ſhrubby.—Gathered by Mr. Maſſon on rocks in the iſlands of Teneriffe and Madeira, from whence it has found its way into the more curious greenhouſes of this and other countries. The habit is much like the laſt, with a thick fleſhy *ſtem*. The chief difference ſeems to conſiſt in the more umbellate *infloreſcence*, accompanied by leafy *bracteas*. The *calyx* is ſquarroſe in a dried ſtate only. *Flowers* like the common Dandelion in ſize and colour.

6. S. *acidus*. Sour Sow-thiſtle. Willd. n. 5.—"Flower-ſtalks branched, naked. Calyx-ſcales ſpreading. Leaves pinnatifid, with oblong-lanceolate, pointed, entire ſegments. Stem ſhrubby."—Gathered in Morocco by Mr. Schouſboe. *Leaves* half a foot long, ſtalked, ſmooth. *Flower-ſtalks* very much branched, ſomewhat forked, and partly umbellate. *Flowers* the ſize of *S. arvenſis*. *Willdenow*.

7. S. *pinnatus*. Wing-leaved Sow-thiſtle. Ait. ed. 1. v. 3. 116. ed. 2. n. 3. Willd. n. 6.—"Flower-ſtalks naked. Calyx ſmooth. Leaves pinnate; leaflets linear-lanceolate, ſlightly toothed. Stem ſhrubby."—Gathered by Mr. Maſſon in Madeira, from whence it was introduced into the greenhouſe at Kew, in 1777, but it ſeems never to have flowered, and is now perhaps loſt.

8. S. *radicatus*. Long-rooted Sow-thiſtle. Ait. ed. 1. v. 3. 116. ed. 2. n. 4. Willd. n. 7.—"Flower-ſtalks naked, ſmooth like the calyx. Stem ſhrubby, almoſt naked. Radical leaves lyrate, ſmooth on both ſides, with

triangular ovate lobes. Brought by Mr. Maſſon from the Canary iſlands, in 1780. It flowers in the greenhouſe in July. *Aiton.*

9. S. *taraxacifolius.* Dandelion-leaved Sow-thiſtle. Willd. n. 8.—Flower-ſtalks ſcaly, panicled. Leaves runcinate, with callous teeth; tapering at the baſe.—Native of Guinea. *Stem* as thick as a gooſe-quill, ſpongy. *Leaves* rather crowded, ſmooth, like Dandelion, but the tips of their teeth are white; the upper ones lanceolate, ſcarcely divided, though minutely toothed; the uppermoſt of all linear and entire. *Common flower-ſtalk* ſix inches, or more, in length, furniſhed with a few leaves, and dividing into a panicle at the top; *partial ones* very ſhort, ſcaly, crowded at the terminations of the panicle. *Calyx* like the Garden Lettuce. *Willdenow.*

10. S. *paluſtris.* Tall Marſh Sow-thiſtle. Linn. Sp. Pl. 1116. Willd. n. 9. Fl. Brit. n. 2. Engl. Bot. t. 935. Curt. Lond. faſc. 5. t. 59. Fl. Dan. t. 606. (S. lævior auſtriacus quintus altiſſimus; Cluſ. Hiſt. v. 2. 147. S. arboreſcens alter; Ger. Em. 294.) — Flower-ſtalks ſomewhat umbellate, briſtly like the calyx. Leaves runcinate; arrow-ſhaped at the baſe; rough in the margin. —In low marſhes, eſpecially about the mouths of great rivers, in Holland, France, England, &c. as well as in Greece, flowering in July and Auguſt. It occurs in ſeveral places bordering on the Thames, below London, as well as in the iſle of Ely. The *root* is perennial, fleſhy, branched, but not creeping. *Stems* herbaceous, from ſix to eight feet high, leafy, angular, hollow, but little branched. *Leaves* runcinate, acute, ſmooth, finely toothed, not rounded, but acutely arrow-ſhaped, at the baſe. *Panicle* umbellate or cymoſe, of ſeveral yellow *flowers*, whoſe *calyx*, as well as the *flower-ſtalks*, is rough with denſe, black, glandular hairs. Haller confounded this with the following, but Curtis has well diſtinguiſhed them.

11. S. *arvenſis.* Corn Sow-thiſtle. Linn. Sp. Pl. 1116. Willd. n. 10; (excluding the reference to Fl. Dan.) Fl. Brit. n. 3. Engl. Bot. t. 674 Curt. Lond. faſc. 4. t. 53. Purſh n. 1. (S. arboreſcens; Ger. Em. 294. Hieracium majus; Fuchſ. Hiſt. 319.) — Flower-ſtalks ſomewhat umbellate, briſtly like the calyx. Leaves runcinate, finely toothed; heart-ſhaped at the baſe. Root creeping.—In fields and about hedges, on a clay ſoil, in the middle or ſouthern parts of Europe, as well as in Pennſylvania; frequent in England, eſpecially towards the ſea, flowering in Auguſt. The *root* is fleſhy and milky, running deep into the ground, and difficult of extirpation. *Stem* but three or four feet high, nearly ſimple. *Leaves* rounded at the baſe. *Flowers* larger than in the laſt, and of a fuller golden hue, externally reddiſh; the tubes of their florets hairy. Dr. Sibthorp thought this the σογχος ἥμερος of Dioſcorides.

12. S. *agreſtis.* Weſt Indian Sow-thiſtle. Swartz. Prodr. 110. Ind. Occ. 1289. Willd. n. 11. (S. lævis; Sloane Jam. v. 1. 255.)—Flower-ſtalks downy, many-flowered. Calyx ſmooth. Stem ſtriated. Leaves ſeſſile, deeply ſerrated or cut.—Native of cultivated ground in the Weſt Indies, along with *S. oleraceus.* *Root* annual. *Stem* two or three feet high, leafy, round, deeply ſtriated, downy. Lower *leaves* ſcarcely divided. *Flowers* terminal and axillary, yellowiſh-white. *Calyx* elongated, ſometimes ſlightly pubeſcent, but little tumid at the baſe, in which this ſpecies differs from the *oleraceus*, as well as in the remarkable ſhortneſs of its *florets*, which have not the appearance of being ligulate, but tubular. *Seeds* long, ſtriated. *Swartz.*

13. S. *lacerus.* Jagged-leaved Sow-thiſtle. Willd. n. 12.—"Flower-ſtalks umbellate, rather downy. Calyx ſmooth. Leaves pinnatifid, toothed; auricled and heart-ſhaped at the baſe." — Native country unknown. *Root* annual. *Stem* two feet high, or more. *Leaves* with lanceolate, angular-toothed ſegments; their baſe dilated, claſping the ſtem, and coarſely toothed. *Flower-ſtalks* branched. *Flowers* the ſize of *S. oleraceus.* *Willdenow.* We have a mutilated ſpecimen gathered by Thunberg at the Cape of Good Hope, which, as far as any judgment can be formed of it, anſwers to the above deſcription; but it is very like the prickly varieties of the common *oleraceus.*

14. S. *anguſtifolius.* Narrow-leaved Sow-thiſtle. Desfont. Atlant. v. 2. 225. Willd. n. 13.—"Leaves pinnate, glaucous, ſmooth; leaflets diſtant, linear, finely toothed. Stem ſcarcely any."—Gathered near Caſsa, in Barbary, by Desfontaines. *Root* perennial, long, ſpindle-ſhaped. *Stem* very ſhort, or none. *Leaves* from four to eight inches long; their teeth withered and whitiſh. *Flower-ſtalks* ſlightly ſcaly, bearing one or more yellow *flowers*, the ſize of *S. arvenſis.* *Calyx* ſmooth, ovate. *Desfont.*

15. S. *umbellifer.* Umbelliferous Cape Sow-thiſtle. Thunb. Prodr. 139. Willd. n. 14. — "Flower-ſtalks hiſpid, ſomewhat umbellate. Leaves oblong-heart-ſhaped, ſerrated."—Native of the Cape of Good Hope.

16. S. *glaber.* Smooth Cape Sow-thiſtle. Thunb. Prodr. 139. Willd. n. 15. — "Flower-ſtalks umbellate, ſmooth like the calyx. Leaves heart-ſhaped, runcinate." —Native of the ſame country.

17. S. *goræenſis.* Scaly Goree Sow-thiſtle. Lamarck Dict. v. 3. 397. Willd. n. 16.—"Flower-ſtalks lateral, ſhort, clothed with membranous ſcales. Leaves lyrate, with little ſpinous teeth."—Native of the iſland of Goree, on the weſt coaſt of Africa. Sparrmann ſent ſeeds to the Paris garden. The *root* is annual. *Stem* a foot high, round, ſmooth, with lax branches. *Leaves* diſtant, claſping the ſtem, ſcarcely more than two inches long, and one broad, ſmooth, green, ſomewhat runcinate. *Flowers* yellow, almoſt ſeſſile along the branches. *Calyx* nearly cylindrical. *Flower-ſtalks* ſmooth, their ſcales with white membranous edges. *Lamarck.*

18. S. *oleraceus.* Common Sow-thiſtle. Linn. Sp. Pl. 1116. Willd. n. 17. Fl. Brit. n. 4. Engl. Bot. t. 843. Curt. Lond. faſc. 2. t. 58. (S. lævis; Ger. Em. 292. Camer. Epit. 279. Matth. Valgr. v. 1. 452.)

β. S. oleraceus; Fl. Dan. t. 682. (S. lævis latifolius; Ger. Em. 292.)

γ. S. aſperior; Ger. Em. 291.

δ. S. aſper; ibid.

ε. S. ſubrotundo folio noſtras; Pluk. Phyt. t. 61. f. 5.

ζ. S. aphyllocaulis, anguſto et oblongo folio, noſtras; Pluk. Phyt. t. 62. f. 4. See alſo t. 61. f. 5.

Flower-ſtalks downy, imperfectly umbellate. Calyx ſmooth. Leaves runcinate, toothed.—A common weed in cultivated land throughout Europe, as well as in other parts of the world to which Europeans have had acceſs, flowering in ſummer and autumn. The *root* is annual, ſpindle-ſhaped. *Herbage* ſmooth, brittle, milky, very various with reſpect to luxuriance, and the quantity of teeth, lobes, or prickles about the edges of its *leaves*; their ſegments, however, are almoſt always acute and runcinate. *Flower-ſtalks* axillary and terminal, rather cymoſe than umbellate, clothed when young with ſoft, white, denſe, cobweb-like, deciduous down. *Corolla* lemon-coloured. *Seeds* angular, with crenate ribs.

19. S. *tenerrimus.* Clammy Sow-thiſtle. Linn. Sp. Pl. 1117. Willd. n. 18. Ait. n. 8. Sm. Fl. Græc. Sibth. t. 790,

t. 790, unpubliſhed. Tour on the Continent, v. 2. 313.—(Hieracium foliis in tenues lacinias profundè ſectis, flore luteo; Pluk. Phyt. t. 93. f. 3. Chondrilla lutea; Bauh. Hiſt. v. 2. 1020.)—Flower-ſtalks downy, ſomewhat umbellate. Calyx hairy. Leaves deeply pinnatifid, with parallel, oblong, toothed, bluntiſh ſegments; their baſe ſomewhat arrow-ſhaped.—Native of rocks and old walls, in Italy, Barbary, Crete, and Cyprus, as well as the ſouth of France, flowering in ſpring. At Rome and Florence it is eaten in ſallads, being of a more delicate, leſs bitter, flavour than *S. oleraceus*, from which it is alſo readily known, by the almoſt pectinate lobes of its *leaves*, hairy viſcid *calyx*, and a much more elegant and ſlender aſpect in the whole plant. The *root* is annual.

20. S. *chondrilloides*. Scaly Sow-thiſtle. Desfont. Atlant. v. 2. 226. Willd. n. 19. Sm. Fl. Græc. Sibth. t. 791, unpubliſhed. (Chondrilla ſicula tragopogonoides maritima; Bocc. Sic. 13. t. 7. f. 1.)—Flower-ſtalks elongated, ſcaly, ſingle-flowered, ſomewhat corymboſe. Calyx ſmooth; its outer ſcales heart-ſhaped. Radical leaves deeply pinnatifid, toothed: thoſe of the ſtem oblong, toothed; heart-ſhaped at the baſe.—Native of ſandy ground, in Barbary, Sicily, and Zante. *Root* perennial. *Herb* ſmooth, ſomewhat glaucous, with more radical, and fewer ſtem-leaves, than the laſt. *Flowers* large, yellow. Outer ſcales of the *calyx*, like thoſe ſcattered over the *flower-ſtalks*, heart-ſhaped, pointed, with a broad, white, membranous border.

21. S. *hiſpanicus*. Spaniſh Sow-thiſtle. Jacq. Hort. Schoenbr. v. 2. 9. t. 143. Willd. n. 20.—Flower-ſtalks ſcaly, ſwelling upward, ſomewhat corymboſe. Calyx-ſcales recurved. Leaves pinnatifid, toothed, claſping the ſtem, glaucous, with white downy dots. Found near Malaga, in Spain. An annual, milky herb, flowering from June to Auguſt. *Jacquin*. *Stem* a foot high, branching from the baſe, ſpreading, glaucous, and covered, like both ſides of the *leaves*, with white dots, which prove, under a magnifier, tufts of down. *Flowers* ſmaller than the laſt, and more like the following, eſpecially in their dark-purple central tint; but differing from both in the recurved points of their *calyx-ſcales*, whoſe white membranous margins, moreover, are criſped, or undulated.

22. S. *tingitanus*. Tangier Sow-thiſtle. Lamarck Dict. v. 3. 397. Willd. n. 21. Sm. Fl. Græc. Sibth. t. 792, unpubliſhed. (S. tingitanus, papaveris folio; Tourn. Inſt. 475. Scorzonera tingitana; Linn. Sp. Pl. 1114. Curt. Mag. t. 142. S. orientalis; Linn. Sp. Pl. 1113. Willd. Sp. Pl. v. 3. 1507. Chondrilla tingitana, floribus luteis, papaveris hortenſis folio; Herm. Lugd-Bat. 657. t. 659.)—Flower-ſtalks ſwelling upward, ſlightly ſcaly. Calyx-ſcales erect, with membranous edges. Leaves pinnatifid, toothed, claſping the ſtem, glaucous, ſmooth.—Native of maritime rocks in Barbary and the Levant. Said to have been cultivated at Chelſea above 100 years ago, but it had long been loſt, and its ſeeds were brought, by the writer of this, from Paris, to the garden of his worthy friend Dr. Gwyn of Ipſwich, in 1787. The plant is annual, flowering in autumn, and its glaucous *leaves*, finely contraſted with the golden, purple-eyed *flowers*, make a ſtriking appearance. The purple-tipped white-edged ſcales of the *calyx* alſo contribute to the beauty and ſingularity of the whole. That this plant is a *Sonchus*, not a *Scorzonera*, is evident to all who look at its *ſeed-down*, and the Linnæan herbarium proves *Scorzonera orientalis*, gathered by Haſſelquiſt, to be the very ſame ſpecies.

23. S. *picroides*. Various-leaved Sow-thiſtle. Lamarck Dict. v. 3. 398. Willd. n. 22. Allion. Pedem. v. 1. 223. t. 16. f. 1. Sm. Fl. Græc. Sibth. t. 793, unpubliſhed. (Scorzonera picroides; Linn. Sp. Pl. 1114. Crepis Dalechampii; Dalech. Hiſt. 562.)—Flower-ſtalks ſwelling upward, ſcaly. Calyx-ſcales cloſe-preſſed, with ſlightly membranous edges. Leaves toothed; radical ones ſomewhat lyrate; the reſt claſping the ſtem, obovate-oblong; uppermoſt linear, nearly entire. Native of the ſouth of France, Barbary, Greece, Cyprus, and the Archipelago; ſent by M. Richard to Kew, in 1773. It is a hardy annual, flowering in ſummer. The *herb* is ſmooth, rather glaucous, varying much in luxuriance, and the *leaves* of the ſame plant differ greatly in ſhape. The radical ones are runcinate and lyrate; being rarely obovate, and merely bordered with ſmall teeth, like the reſt. *Flowers* of an uniform yellow, above an inch broad, ſolitary, on a ſlightly ſcaly elongated ſtalk, at the end of each branch. The ſcales of the ſtalks, like the outer ones of the *calyx*, are heart-ſhaped, pointed, ſmall, cloſe and flat, with a narrow white edge. Although Plukenet's t. 61. f. 5, cited by Linnæus and Willdenow, bears ſome reſemblance to the leaves of the ſpecies before us, yet that, being of Engliſh growth, can hardly be any thing elſe than a variety of *S. oleraceus*, to which we have often ſeen near approaches in that variable plant; ſee n. 18, ζ.

24. S. *crepioides*. Hawkweed Sow-thiſtle. (Scorzonera crepioides; Poiret in Lam. Dict. v. 7. 25.)—Flower-ſtalks naked, ſomewhat panicled. Stem much branched, rather downy as well as the calyx, whoſe outer ſcales are oval.—Gathered by M. Poiret, on the coaſts of Barbary. His deſcription of the fine, ſilky, ſimple *ſeed-down*, and naked *receptacle*, induces us to refer the plant to *Sonchus*. He deſcribes it as having the aſpect of *Crepis biennis*; but he knew not its *leaves*, nor the lower part of its herbage. Each diviſion of the *ſtem* has, at its baſe, a little, claſping, linear-lanceolate, pointed, downy leaf. *Flowers* of a middle ſize, yellow. *Calyx* oval, cloſe; its inner ſcales long, narrow, downy, or farinaceous; outer very ſhort and oval.

25. S. *dichotomus*. Forked Sow-thiſtle. Willd. n. 23. (Scorzonera dichotoma; Vahl. Symb. v. 2. 89. Desfont. Atlant. v. 2. 450. Lactuca flava; Forſk. Ægypt-Arab. 143.)—“Flower-ſtalks ſcaly, of equal thickneſs throughout. Stem forked, almoſt leafleſs. Radical leaves runcinate.”—Gathered by Forſkall in the vale of Surdúd, in Arabia Felix, and by Vahl in the kingdom of Tunis. The *herbage* is ſmooth. *Stems* divided from the baſe into rigid forked branches, bearing in their lower part two lyrate *leaves*, like the radical ones, but otherwiſe only ſmall, lanceolate, or ovate, entire ones under each ſubdiviſion. *Flowers* terminal, ſolitary, yellow. *Calyx* very ſmooth; its outer ſcales ovate, looſe, with broad white edges.

26. S. *Plumieri*. Pyrenean Blue Sow-thiſtle. Linn. Sp. Pl. 1117. Willd. n. 24. Ait. n. 11.—Flower-ſtalks panicled, ſmooth, with claſping, long-pointed bracteas. Leaves pinnatifid, pointed, runcinate —Native of the Pyrenees. It is alſo found, though rarely, on the Alps of Switzerland, having been obſerved by M. Favrod, on the mountain called Deut de Jamare, and above Queiſimen, in Teufelsgraben. We have ſeen this fine plant in ſome curious gardens, but cannot find it any where figured. The *root* is perennial. *Stem* often as tall as a man, round, branched, ſtriated, leafy, ſmooth and glaucous like every other part of the herbage. *Leaves* one or two feet long, deeply pinnatifid, with numerous, pointed, oppoſite, parallel, ſharp-toothed ſegments, and a terminal, pointed, triangular lobe; their baſe dilated, claſping the ſtem; under ſide moſt glaucous.

Flowers numerous, large, pale blue, leſs vivid than thoſe of the Wild Succory. *Bracteas* ſmooth, rounded at the baſe, with long, taper points. *Calyx* ſmooth. Its outer ſcales ſomewhat cordate.

27. S. *macrophyllus*. Large-leaved Hairy Blue Sow-thiſtle. Willd. n. 25. Purſh n. 3. (S. canadenſis; Froelich in Uſter's Annal. v. 1. 29. S. n. 1; Gronov. Virg. ed. 2. 115. "Chondrilla ſylveſtris alta, flore cæruleo ſpecioſo, foliis ſinuatis longis acuminatis alternis, levitèr hirſutis, caule ad cacumen ramoſo, ſemine nigro, pappis albis et quaſi argenteis inſtructo; Clayt. n. 139.")—Flower-ſtalks hairy, panicled. Leaves lyrate; heart-ſhaped at the baſe; hairy beneath.—In ſhady low grounds, near ſprings, from Pennſylvania to Carolina, flowering in Auguſt and September. From four to ſeven feet high. *Flowers* blue, the ſize of *Cichorium Intybus*. *Root* tuberous. *Purſh*. Mr. Froelich, above quoted, deſcribes this ſpecies as having for ſome years been cultivated in the botanic garden at Erlang, with ſimple, ſpatulate radical *leaves* a foot long, which wither before the *flowers* come to perfection; their ribs and veins hairy beneath; the *ſtem-leaves* lyrate, toothed, ſomewhat fringed; much dilated, heart-ſhaped, rounded, and finely toothed, at the baſe; paler and hairy beneath; their terminal lobe very large, triangular, in ſome degree heart-ſhaped; the intermediate ones ovate, obtuſe, unequal: *upper leaves* more ſimple, ſpatulate, very broad at their baſe, with ſcarcely any intermediate lobes. *Panicle* with alternate, hairy, ſubdivided, unequal branches; the upper ones longeſt and moſt compound. *Flower-ſtalks* unequal, erect, denſely clothed with glutinous hairs, and bearing one or two ſcales. *Bracteas* lanceolate, pointed, hairy, much ſhorter than the partial ſtalks. *Calyx* half an inch long, cylindrical, pale violet; its inner ſcales about fourteen, linear, equal, thin at the edges; outer ſhorter, ſcattered, unequal, cloſely imbricated, a little hairy at the back. *Florets* from thirty-four to forty, of a purpliſh fleſh-colour, with hairy tubes. *Seeds* ovate-oblong, triangular, ſtriated. *Down* ſeſſile, roughiſh, very white. *Odour* of the plant like opium, diſagreeable, as well as the *taſte*, which is bitter. Of this little-known ſpecies we ſuſpect there is an imperfect ſpecimen in the Linnæan herbarium, firſt marked as having been communicated by Kalm, and then by Gmelin, a reference to *Sonchus*, n. 12. Fl. Sibir. v. 2. 12. t. 4. f. 1, being at the back. This laſt is an error, the ſaid figure anſwering beſt to *S. alpinus* of moſt authors, *cæruleus* of Fl. Brit. which we ſuſpect to have been Gmelin's plant. He mentions having ſeen but a ſingle ſpecimen, or we ſhould think it had been one of his, now alſo in our hands, which Linnæus, by a parallel error to the above, has marked as coming from Kalm, and deſcribed by the name of *canadenſis*. At leaſt, Linnæus's having confuſed himſelf about theſe two ſpecimens, may account for his deſcribing as a Canadian plant, what no one has ever found in that country; for Mr. Purſh evidently admits it on report only, by the name of *alpinus*.

28. S. *cæruleus*. Alpine Hairy Blue Sow-thiſtle. Camer. Epit. 281. Fl. Brit. n. 1. Engl. Bot. t. 2425. (S. canadenſis; Linn. Sp. Pl. 1115. S. montanus; Lamarck Dict. v. 3. 401. S. alpinus; Willd. n. 26. Ait. n. 12, excluding the reference to Fl. Lapp. Purſh n. 4. Froelich in Uſt. Annal. v. 1. 26. Fl. Dan. t. 182. S. cæruleus latifolius; Bauh. Hiſt. v. 2. 1005. S. flore cæruleo; Ger. Em. 294. S. n. 20; Hall. Hiſt. v. 1. 9.)—Flower-ſtalks hairy, racemoſe, with ſetaceous bracteas. Leaves ſomewhat lyrate; arrow-ſhaped at the baſe; their terminal lobe triangular, very large.—Native of alpine paſtures in various parts of Europe, flowering in July and Auguſt. The late Mr. G. Don found it on Lochnagore, Aberdeenſhire, which is the only authority for retaining it in our Flora Britannica; *S. alpinus* of former Britiſh writers being only *Cichorium Intybus*, admitted on the word of a Northumberland writer, ſcarcely more correct than he who deſcribed the lemon, as growing on the bleak Welſh crag of Penmaen Mawr. This ſpecies has a fleſhy, perennial, tufted *root*. *Stems* about a yard high only, ſimple, leafy. *Leaves* conſiſting chiefly of a large, triangular, toothed, ſharply-pointed lobe, on a bordered, ſlightly pinnatifid, ſtalk, claſping the ſtem with an arrow-ſhaped baſe; the under ſide glaucous, with now and then a few hairs on the rib: the uppermoſt *leaves* are often quite linear, and merely fringed. *Cluſter* terminal, ſolitary, erect, many-flowered, ſcarcely compound, its ſtalks, like the *calyx*, rough with copious, red, glutinous, prominent hairs. *Bracteas* linear or ſetaceous. *Corolla* of a fine blue. *Anthers* red. *Seed-down* roughiſh.

Linnæus originally confounded this with his true *S. alpinus*, which has given riſe to much confuſion and controverſy; for authors, indolently following ſome of his ſynonyms, without regarding his definitions, have been thus led widely aſtray; nor can we ſcreen their errors, by allowing them to change a fixed and primary Linnæan name. The learned and candid Mr. Froelich only has any claim to attention on this ſubject. He would call this plant *alpinus*, becauſe Linnæus has, in *Philoſophia Botanica*, p. 273 & 274, inadvertently ſpoken of his true *alpinus*, by the name of *lapponicus*. So has he there called his *oleraceus*, *lævis*; his *paluſtris*, *belgicus*; and his *Cichorium Intybus*, *ſcanenſe*; all which errors he has corrected in his own copy of the work; nor did he dream of their miſleading any body. Even Lamarck has uſed the name of *alpinus*, according to its original deſtination, and ſo we ſhall preſume ſtill to apply it; ſee the following ſpecies.

29. S. *alpinus*. Alpine Scaly Blue Sow-thiſtle. Linn. Sp. Pl. 1117. Fl. Suec. ed. 2. 269, excluding all, except Linnæan, ſynonyms. Fl. Lapp. ed. 2. 240. Lamarck Dict. v. 3. 400. Sm. Plant. Ic. t. 21. (S. lapponicus; Froelich in Uſt. Annal. v. 1. 26. Willd. n. 27.)—Flower-ſtalks ſcaly, racemoſe, erect. Leaves pinnatifid, pointed, toothed, ſmooth; glaucous beneath. Stem ſimple.—Found by Linnæus on the ſides of hills, and in valleys, among the Lapland alps, where it is extremely common, though not known in any other part of the world. The Laplanders peel the ſtalks, before flowering, and eat the fleſhy part, which Linnæus thought too bitter, without the uſual ſeaſoning of a ſallad. He ſpeaks of this plant as extremely handſome, the height of a man, or taller, with a ſtraight, rigid, leafy *ſtem*. The *leaves* are ſmooth and ſhining, deeply pinnatifid, ſharply toothed; rounded, but not dilated nor claſping, at the baſe; glaucous beneath. *Cluſter* more or leſs compound, long, denſe; its *ſtalks* not at all hairy or downy, but clothed with imbricated, concave, acute, ſheathing ſcales. *Flowers* blue, about half the ſize of the laſt, but much more numerous. *Calyx* ovate, ſmooth. The late profeſſor Willdenow informed us, in 1796, that this rare plant was then growing luxuriantly, in the garden of Mr. Krauſe, at Berlin. He favoured us with ſeeds, but they did not ſucceed. The *root* is marked as biennial.

30. S. *leucophæus*. Pale-blue American Sow-thiſtle. Willd. n. 28. Purſh n. 5. (S. ſpicatus; Lamarck Dict. v. 3. 401.)—Flower-ſtalks ſcaly, racemoſe, drooping. Leaves pinnatifid, toothed, ſmooth. Stem wand-like, panicled.—On the borders of woods, by road ſides, from New England to Virginia, flowering from July to September. *Root* biennial. *Flowers* ſmall, white tinged with blue. *Purſh*. Lamarck

ſays the *ſtem* is only two or three feet high. *Leaves* narrow; the upper ones ſmall, linear, and entire.

31. S. *floridanus.* Small-flowered Florida Sow-thiſtle. Linn. Sp. Pl. 1118. Willd. n. 13. Purſh n. 6.—Flower-ſtalks panicled, diſtantly ſcaly. Leaves ſomewhat lyrate, minutely toothed, ſmooth, with a large, triangular, acute, terminal lobe.—On road ſides, in the ſhady woods of Virginia and Carolina, flowering from July to September. *Root* biennial. *Leaves* a ſpan long, of two large lobes, beſides the much larger terminal one; narrow and linear at the baſe. *Panicle*, or *cluſter*, doubly branched, ſpreading. *Flowers* very ſmall, blue. Mr. Purſh ſays, this plant has been uſed for curing the bite of the rattle-ſnake, in the ſame manner as his *Prenanthes ſerpentaria*, and is known by the name of Gall of the earth.

32. S. *acuminatus.* Pointed-leaved Sow-thiſtle. Willd. n. 30. (Lactuca villoſa; Jacq. Hort. Schoenbr. v. 3. 62. t. 367?) —" Flower-ſtalks ſlightly ſcaly, panicled. Radical leaves ſomewhat runcinate; thoſe of the ſtem ovate, pointed, ſtalked."—In low ſhady places, from Pennſylvania to Virginia, flowering in Auguſt and September. Biennial. *Flowers* ſmall, blue. *Purſh.* *Stem-leaves* tapering at each end, and furniſhed at each ſide, in the middle, with ſmall pointed teeth. It differs from *S. floridanus* in theſe leaves being undivided. They are alſo ſlightly hairy beneath. The *panicle* was ſlender, compoſed of few *flowers*, in Willdenow's wild ſpecimen, and the *ſeed-down* ſeſſile. Jacquin's figure exhibits a triply-compound *panicle*, of innumerable ſmall pale-blue *flowers*, and he unluckily does not mention the *ſeed-down*. We know nothing of this ſpecies, but from theſe authorities. It appears akin to the laſt, though ſufficiently diſtinct.

33. S. *pallidus.* Pale-yellow Canadian Sow-thiſtle. Willd. n. 31. Ait. n. 14. Purſh n. 8. (Lactuca canadenſis; Linn. Sp. Pl. 1119.)—Cluſter compound, with ſcaly ſtalks. Leaves lanceolate, toothed, ſmooth, claſping the ſtem; the upper ones taper-pointed.—On road ſides, and in woods, from Canada to New England, flowering from July to September. Perennial. *Flowers* ſmall, yellow. *Purſh.* The ſcales of the *flower-ſtalks* are ovate, pointed, crowded and recurved. *Cluſter* denſe. *Calyx* very ſmooth. *Seed-down* quite ſeſſile. The *leaves* are not properly ſword-ſhaped. Mr. Purſh cites under this ſpecies Robert's Icones t. 148 and 151, which we have not been able to conſult.

34. S. *pulchellus.* Beautiful Blue Sow-thiſtle. Purſh n. 9.—" Flower-ſtalks ſcaly, in a corymboſe cluſter. Stem-leaves ovate-oblong, acute, entire, ſmooth; with a claſping heart-ſhaped baſe."—On the banks of the Miſſouri, flowering in September. Perennial. *Flowers* large, of a beautiful blue. *Purſh.*

35. S. *ſibiricus.* Willow-leaved Sow-thiſtle. Linn. Sp. Pl. 1118. Willd. n. 32. Ait. n. 15. (S. n. 11; Gmel. Sib. v. 2. 11. t. 3. Lactuca ſalicis folio, n. 211 and 212; Amm. Ruth. 150.)—Flower-ſtalks corymboſe, with diſtant lanceolate ſcales. Leaves lanceolate, ſeſſile; the upper ones entire; lower variouſly toothed.—Found throughout Siberia, as well as about the river Wolga, and in ſome parts of Ruſſia and Finland. The *root* is perennial, creeping extenſively. *Stem* from one to four feet high, leafy, wand-like; ſometimes branched in the upper part. *Leaves* numerous, about four inches long, very ſmooth and even; rather glaucous at the back. *Flowers* blue, about an inch in diameter, compoſing a level-topped corymb.

36. S. *tataricus.* Tartarian Sow-thiſtle. Linn. Mant. 572, excluding the ſynonym. Willd. n. 33. Ait. n. 16.—Flower-ſtalks racemoſe, nearly naked. Leaves lanceolate, runcinate.—Native of Siberia and Tartary. Perennial, flowering in June and July. A rather larger plant than the laſt; the teeth of its *leaves* large, pointing backward. *Flowers* blue, in compound cluſters, terminating the ſtem and branches.

37. S. *prenanthoides.* Long-cluſtered Sow-thiſtle. " Marſchall von Bieberſtein." Fiſcher MSS.—Flower-ſtalks racemoſe, lateral and terminal, ſcaly, downy. Leaves elliptic-oblong, toothed, ſomewhat fiddle-ſhaped.—Native of mount Caucaſus. The *ſtem* is round, terminating in a long ſeries of alternate, ſhortiſh, ſomewhat compound, *cluſters*, whoſe partial ſtalks are cottony and ſcaly. The *flowers* ſeem to be blue or purpliſh. *Leaves* ſmooth, ſomewhat ſtalked, three or four inches long, an inch and half broad, finely toothed; the upper ones diminiſhing into lanceolate narrow *bracteas*.

SONCINO, in *Geography*, a town of Italy, on the Oglio; 8 miles E.N.E. of Crema.

SONDAU, a town of Brandenburg, in the duchy of Magdeburg; 50 miles N.N.E. of Magdeburg.

SONDELY, a town of Norway, in the province of Bergen; 30 miles S.S.W. of Romſdal.

SONDERBORG, a ſea-port town of Denmark, on the S. coaſt of the iſland of Alſen, with a royal palace, and one of the beſt harbours in Denmark. In this palace Chriſtian II. king of Denmark, was confined as a priſoner for 13 years: the inhabitants are chiefly ſeamen: 16 miles E.N.E. of Flenſborg. N. lat. 54° 57′. E. long. 9° 59′.

SONDERSHAUSEN, a town of Germany, in the county of Schwartzburg, ſituated on the Wipper. On an eminence without the town ſtands the palace, where the ruling prince of the Sonderſhauſen line uſually reſides; 20 miles N.E. of Mulhauſen. N. lat. 31° 22′. E. long. 10° 57′.

SONDERSITZ. See URSITZ.

SONDHEIM, a town of the duchy of Wurzburg; 7 miles N. of Biſchoffsheim.

SONDRE GRUND, or BOTTOMLESS, an iſland in the South Pacific ocean, diſcovered by Le Maire and Schooten, in 1616; about 20 leagues in circumference, long but not broad. It appeared covered with trees, among which were palmetoes and cocoa-nut trees. It had no anchoring ground. The inhabitants were naked, except a piece of mat round the middle, of a yellowiſh or reddiſh-brown colour, and black hair; their ſkin was marked with many figures: they were covetous of iron, and thieves. S. lat. 15°. W. long. 148°.

SONDRIO, or SONDERS, a town of Italy, and capital of the Valteline, partly on a plain and partly on the ſide of a rock, in a romantic ſituation, at the extremity of a narrow valley, on a ſmall river which runs into the Adda; 15 miles E. of Chiavenna. N. lat. 46° 6′. E. long. 9° 50′.

SONE, a town of Bengal; 8 miles S.E. of Ramgur.

SONEGA, a town of Holland, in Frieſland; 9 miles E. of Kuynder.

SONEGUERA, a town of Mexico, in the province of Honduras; 32 miles N. of St. Jorge de Olancho. N. lat. 15° 15′. W. long. 86° 40′.

SONEHUTCH, a town of Hindooſtan, in Malwa; 30 miles N.E. of Indore.

SONENBERG, a town of Germany, in the county of Pludentz; 4 miles N. of Pludentz.—Alſo, a town of the New Mark of Brandenburg; 6 miles E. of Cuſtrin.

SONEPOUR, a town of Hindooſtan, in Oriſſa, on the Mahanada; 38 miles S. of Sumbulpour. N. lat. 20° 47′. E. long. 83° 40′.

SONERGONG. See Sunergong.

SONEWALDT, a town of Luſatia; 8 miles S. of Luckau.

SONEY, a town of Hindooſtan, in Malwa; 9 miles E. of Saurungpour.

SONG, a town of Africa, in Bambarra, on the Niger. N. lat. 13° 54′. W. long. 3° 55′.

Song, a town of China, of the third rank, in Ho-nan; 37 miles S.S.W. of Ho-nan.

Song Song, a ſmall iſland in the Indian ſea, near the coaſt of Africa. S. lat. 8° 12′.

SONG, in *Poetry*, a little compoſition, conſiſting of ſimple, eaſy, natural verſes, ſet to a tune, in order to be ſung.

Each ſtanza of a ſong is called a *couplet*.

The ſong bears a great deal of reſemblance to the madrigal, and more to the ode; which is, indeed, nothing but a ſong, according to the ancient rules.

Its object is uſually either wine or love, whence M. le Brun defines a modern ſong, to be either a ſoft and amorous, or a briſk and Bacchic thought expreſſed in few words.

Indeed, this is to reſtrain it to too narrow bounds; for we have devout ſongs, ſatyrical ſongs, and panegyrical ſongs. But, be the ſong what it will, the verſes are to be eaſy, natural, and flowing; and are to contain a certain harmony, which neither ſhocks the reaſon nor the ear; and which unites poetry and muſic agreeably together.

Anciently, the only way of preſerving the memory of great and noble actions, was by recording them in ſongs; and, in America, there are ſtill people who keep their whole hiſtory in ſongs.

Songs have at all times, and in all places, afforded amuſement and conſolation to mankind: every paſſion of the human breaſt has been vented in ſong; and the moſt ſavage as well as civilized inhabitants of the earth have encouraged theſe effuſions. The natives of New Zealand, who ſeem to live as nearly in a ſtate of nature as any animals that are merely gregarious, have their ſongs, and their *improviſatori;* and the ancient Greeks, during every period of their hiſtory and refinement, had their *ſcolia* for almoſt every circumſtance and occaſion incident to ſociety.

Singing was ſo common among the ancient Romans as to become proverbial. Phædria, in the Phormio of Terence, begs Dorio to hear him, he has but one word to offer; when Dorio tells him he is always ſinging the ſame ſong. Horace ſpeaks of the ſame affectation among the ſingers of his time as prevails with the preſent; never to ſing when they are entreated, or to deſiſt if no one wiſhes to hear them. And ſome idea of the cultivated ſtate of muſic in Gaul, ſo early as the fifth century, may be acquired from a paſſage in one of the epiſtles of Sidonius Apollinaris, who, in his character of king Theodoric the Goth, ſays, that "this prince was more delighted with the ſweet and ſoothing ſounds of a ſingle inſtrument, which calmed his mind, and flattered his ear by its ſoftneſs, than with hydraulic organs, or the noiſe and clangor of many voices and inſtruments in concert."

Clothaire II. in the ſeventh century, having gained a great victory over the Saxons, it was celebrated by a Latin ſong in rhyme, which the annaliſts tell us was ſung with great vociferation all over the kingdom.

As the origin of ſongs and the formation of the language of every country are ſo nearly coeval, we hope the reader will allow us to beſtow a few columns on a ſubject which, though it may not be thought abſolutely neceſſary for a muſical lexicographer, or even hiſtorian to trace, yet it lies ſo near his path, that he can hardly proceed on his way without its being impreſſed on his mind fortuitouſly. For the *ſongs* of the ancient Greeks, ſee Scolia.

But in enquiring after the moſt ancient ſongs in modern languages, we ſhall not enter upon the merits of a queſtion which has been much agitated in France during the middle of the laſt century, "Whether the preſent language of that country was firſt cultivated in the northern or ſouthern provinces?" The origin of all inventions, after having been ſuffered by ignorance and idleneſs to ſleep for many ages, is ſo difficult to aſcertain, that if the inhabitants of the kingdoms which gave them birth, where information is moſt likely to be furniſhed, are unable to bring them to light, it would be arrogance in a foreigner to attempt it. The French critics and antiquaries all agree that the capital was the laſt place to cultivate the vulgar tongue, and to receive the firſt eſſays of thoſe who made it the vehicle of their thoughts. Fontenelle ſays the firſt ſparks of poetry appeared chiefly at the two extremities of the kingdom, in Provence and Picardy. "The Provençaux," ſays he, "warmed by a more genial ſun, ought to have had the ſuperiority; but the inhabitants of Picardy are their inferiors in nothing." M. de la Ravaliere gives the honour of priority to the writers of Normandy; and Fauchet and Paſquier, ſeparating the French poetry from the Provençal, challenge the admirers of the Troubadours to produce verſes of their writing of equal antiquity with the ſpecimens of French poetry which they have exhibited. However, the Provençal bards have lately had many able champions, among whom M. de Lacurne de Sainte Palaye, and his faithful 'ſquire, M. Millot, have diſtinguiſhed themſelves. And though it cannot be denied but that fragments of ſongs ſubſiſt in the French language of higher antiquity than in the dialect of Provence, yet, as we have been able to find no melodies that have been ſet to a modern language more ancient than thoſe that have been preſerved in the Vatican library to the ſongs of the Troubadours, we ſhall begin our enquiries concerning the origin of vulgar dialects in Europe, by endeavouring to trace the firſt formation of the language of Provence.

Every refined and poliſhed nation has a vulgar language in its remote provinces, and even in its capital, among the common people, in which there are innumerable words and phraſes that have never been admitted into books. This muſt doubtleſs have been the caſe with the Romans; and it is the opinion of ſome perſons of great eminence in literature, among whom may be numbered the learned cardinal Bembo, and the marquis Maffei, that the ancient Romans had at all times an oral vulgar language which was different from that of books; and that this colloquial language, leſs grammatical and elegant than that of the learned, was carried by the Romans into all the provinces under their dominion. It is therefore probable that this, and not the written language of Italy, was the mother of the Provençal, Sicilian, Italian, and Spaniſh dialects.

But ſuppoſing ſuch a language as Cicero's was ever ſpoken, it could not be laid aſide for another all at once; and when we are told of a particular period or century, during which the Latin tongue ceaſed to be ſpoken in France or Italy, and the Provençal, French, or Italian begun; credulity itſelf is ſtaggered, and unable to reconcile it to probability. Every language is long ſpoken before it is written; and though the firſt poet of Italy or Provence, who committed his verſes to writing in the vulgar tongue, could be named, no one would venture to tell us by whom it was firſt ſpoken.

The learned Maffei is of opinion that there was a *vulgar* language in Italy long before the irruptions of the Lombards, Goths, or Franks; and has traced its uſe as early as the time of Quintilian, who tells us, that he had often heard the crowd in the Circus applaud, or demand ſomething of the champions, in a barbarous language; that is, in a vulgar and plebeian dialect, different from pure Latin. Sammonicus, who lived in the time of Septimius Severus, names the vulgar language. And both Pliny and St. Jerome ſpeak of the military language as of that kind; the latter even tells us that Fortunatianus, biſhop of Aquileia, wrote a commentary on the Evangeliſts in this vulgar language, *ruſtico ſermone*, during the time of Conſtantine. But this was a ſingular inſtance, which was not imitated.

It appears, however, from the Dialogues of St. Gregory the Great, written 593, that there was then a language merely colloquial at Rome. For he tells us that a new convert, of whom he is ſpeaking, was ſent to a convent with two veſſels of wine, which the vulgar call flaſks.

And Gregory of Tours, ſo early as 572, complains of this vulgar or ruſtic tongue gaining ground in France, and being more in favour than Latin, the language of the learned.

It was therefore by degrees that Latin ceaſed to be underſtood by the common people, and the Romance language had admiſſion into books. And in 813 it was ordered by a canon at the council of Tours, that the biſhops ſhould be employed in tranſlating homilies into the Roman ruſtic tongue, that they might be the more eaſily underſtood by the common people. The ſame canon, we are told, was renewed in a council at Arles in 851.

In the ninth century hiſtorians tell us, that Charlemagne and his ſons and ſucceſſors ſpoke the Romance language, ſpecimens of which may be ſeen in Fauchet, Paſquier, and ſeveral other writers on the French language. And in the twelfth century it began to be the general language of poets and polite writers. Some of the ſermons written and preached by St. Bernard, about 1137, in this language, are ſtill preſerved among the MSS. of the convent of Feuillans, in the rue St. Honoré at Paris.

The colloquial language uſed only in familiar converſation was called by the Romans *ſermo uſualis, quotidianus, pedeſtris, vulgaris, militaris, ruſticus*, &c. It is ſuppoſed by M. Bonamy, as well as by others, that from this vulgar Latin not only the French language and its different dialects but the Spaniſh and Italian are derived. Indeed, it is moſt probable that the Latin tongue, in its periods of greateſt purity, was only the language of the learned, in the Roman provinces remote from the capital; and that it was never ſo generally cultivated in other times as to exclude the vulgar dialect.

In the frequent revolutions and ſtruggles for empire during theſe ages, the Roman language muſt have been debaſed and corrupted, while new tongues were forming, which, though not ſufficiently fixed and grammatical to be uſed in books, were doubtleſs long the vulgar and colloquial dialects before the Latin ceaſed to be the common language of the learned.

It was about this time that the art of rhyming, or uniſonous terminations of verſes, ſtole into poetical compoſition, in a manner which the learned and judicious author of an Eſſay on the Language and Verſification of Chaucer, ſeems to have traced to its ſource. Leonine verſes, ſuppoſed to have been ſo called from a pope or monk Leo, their author, in the ſeventh century, are by ſome thought the firſt attempt at rhyme; while others imagine the hymn to St. John the Baptiſt, by Paul Diaconus, written about the latter end of the eighth century, to be not only rendered memorable by Guido's ſcale, but by having been the model of all other monkiſh rhymes in Latin, as well as in modern languages. *Ut queant laxis*, &c.

But neither of theſe genealogies ſatisfies all enquirers. Gravina thinks it as abſurd to aſcribe the invention of rhyme to any one writer, as to attribute to an individual the propagation of the plague, which is cauſed by the univerſal contagion of the air.

The Arabs had rhyme, according to Don Calmet, before the time of Mahomet, who died 632, and in the ſecond century uſed a kind of poetry in meaſures ſimilar to the Greek, and ſet to muſic. See RHYME.

While the new languages were unſettled, and but partially known, even in the ſingle kingdom or province where they were forming, it was not uncommon to write half a poem in Latin and half in a vulgar tongue. Indeed Dante has left a poem in three languages, Latin, Provençal, and Italian; and Rambaud de Vachieras, a Provençal poet, in five.

Petrarca and Muratori think that the Sicilians firſt compoſed and wrote ſongs in a vulgar language; that from them the cuſtom went into Provence, and from Provence into Italy. Indeed Sicily and Provence were long under the dominion of the ſame princes, and the ſame language may have been cultivated at the courts of both countries; but as no veſtiges remain of Sicilian poetry reſembling the Provençal, the opinions of theſe authors, however eminent, and, on other accounts, reſpectable, while unſupported by reaſons and facts, can have but little weight.

Cardinal Bembo, however, was of opinion that the firſt rhymers and poets who wrote in a modern language were of Provence; after them the Tuſcans, who had more aſſiſtance from them in their poetry than from any other people. And both Creſcembeni and Gravina make the ſame conceſſion.

Noſtradamus, in his lives of the Provençal poets, ſays that Provence was called the mother of Troubadours and Minſtrels; and that Dante, Petrarca, Boccaccio, and other Tuſcan poets, enriched both their language and fancy from the productions of his countrymen. However, as no *verſi ſcioliti*, or poetical lines without rhymes, are to be found in the Provençal poets, though they abound among the Italians, it is natural to ſuppoſe that in theſe meaſures of blank verſe the Italians imitated their anceſtors the Romans, and that in rhyming, the Provençals were their models.

It was the opinion of Voltaire that this language began to be formed in the ninth century, out of Latin and Teutonic; that it was the mother of French, Spaniſh, and Italian; "continued in favour till the reign of the emperor Frederic II. and is ſtill ſpoken in ſome villages of the Griſons, and near Switzerland."

Carpentier derives the word Troubadour from *Troba*, Provençal, *figmentum. Hinc Troubadours appellati poetæ Provinciales.*

It was in the eleventh century, during the firſt cruſade, according to the abbé Millot, that Europe began to emerge from the barbarous ſtupidity and ignorance into which it had long been plunged. And while its inhabitants were exerciſing every ſpecies of rapine, plunder, and pious cruelty in Aſia, art, ingenuity, and reaſon, inſenſibly civilized and ſoftened their minds.

It was then that the poets and ſongſters known by the name of Troubadours were multiplied, and their profeſſion honoured by the patronage and encouragement of the count of Poitou, and many other powerful princes and barons, who had themſelves ſucceſsfully cultivated poetry and muſic. At the courts of theſe munificent patrons they were treated with the greateſt conſideration and reſpect. The ladies, whoſe charms they celebrated, gave them the moſt generous and flattering reception; and ſometimes diſdained not even to liſten with compaſſion to tales of tenderneſs, and deſcriptions of the havock which the irreſiſtible charms of theſe ſublunary divinities of chivalry had made in their hearts. The ſucceſs of a few inſpired the reſt with hope, and excited exertions in the exerciſe of their art, which impelled them towards perfection with a rapidity that nothing but the united force of emulation and emolument could occaſion.

As theſe founders of modern verſification, theſe new poetical architects, conſtructed their poems upon plans of their own invention; and as all claſſical authority was laid aſide, either through ignorance or deſign, each individual gave unlimited indulgence to fancy in the ſubject, form, and ſpecies of his compoſition. And it does not appear, during the cultivation and favour of Provençal literature, that any one Troubadour ſo far outſtript his brethren in the approaches he made towards perfection, as to be conſidered as a model for his ſucceſſors. We find, though military proweſs, hoſpitality, Gothic gallantry, and a rage for feaſts and revelry prevailed, that taſte, refinement, and elegance, were never attained during this period, either in public or private amuſements. The want of originality of compoſition is frequently lamented when licence is repreſſed by laws, and the wild effuſions of an ardent imagination are bounded by authority; but the productions that have been preſerved of the Provençal bards, which may be called the offspring of writers in a ſtate of nature, ſeem to prove the neceſſity of rule, order, and example, even in the liberal arts as well as the government of a free ſtate. For the progreſs of taſte muſt ever be impeded by the ignorance and caprice of thoſe who cultivate an art without ſcience or principles.

During near two centuries after Guido's arrangement of the ſcale and invention of the time-table aſcribed to Franco, no remnants or records of ſecular muſic can be found except thoſe of the Troubadours, or Provençal poets. And though in the ſimple tunes which have been preſerved of theſe bards, no time is marked, and but little variety of notation appears, yet it is not difficult to diſcover in them germs of the future melodies, as well as poetry, of France and Italy. Unluckily the poetry and muſic of the Troubadours of Provence were not for a long time called into notice by writers poſſeſſed of thoſe blandiſhments of ſtyle or manner which faſcinate, and render whatever ſubject they treat intereſting to the generality of readers. Fauchet, Paſquier, and Noſtradamus have written in a language that is now become ſo uncouth and difficult, that few have the courage to attempt acquiring information or amuſement from it; and Muratori and Creſcembeni, who are reſpected for their diligence and exactitude, are certainly dry and dull narrators of facts which promiſe delight to every lover of literature; nor do we remember, in conſulting their voluminous writings, ever to have found them guilty of hazarding a ſingle reflection or conjecture that has embelliſhed the ſubject, or rendered it amuſing. But this cenſure muſt not be applied to Sainte-Palaye, Bonamy, la Ravaliere, and Barbazan, who, in the Memoires de Litterature and elſewhere, have not only embelliſhed, but nearly exhauſted the ſubject. Indeed, the period of Provençal poetry is intereſting to literature, and the melody to which it was ſung is a ſubject of curious enquiry to a muſical hiſtorian; for it is generally allowed that the Troubadours, by ſinging and writing in a new tongue, occaſioned a revolution not only in literature but the human mind. And as almoſt every ſpecies of Italian poetry is derived from the Provençals, ſo air, the moſt captivating part of ſecular vocal melody, ſeems to have had the ſame origin. At leaſt the moſt ancient ſtrains that have been ſpared by time, are ſuch as were ſet to the ſongs of the Troubadours. See TROUBADOURS.

Songs ſeem in a particular manner to belong to the language of Italy. The ancient Romans were no great ſongſters; and by what degrees the Latin language became Italian, would be a tedious and difficult enquiry. We know when the muſical drama or opera was eſtabliſhed, and conſequently when opera airs, with inſtrumenatal accompaniments, began firſt to be cultivated; but theſe are not the ſubjects of our preſent reſearch: but when national melodies, for ſuch every country has, were firſt applied to ſongs in the Italian language, a dialect which has long been univerſally allowed to be more favourable to ſinging than any one which the numerous combinations of letters in all alphabets of modern times has produced, we are ignorant. And if the French, Provençal, and Spaniſh dialects can be deduced from the Latin, how much more eaſy is it to trace the Italian from that ſource? which is itſelf frequently ſo near pure and claſſical Latin, that no other change or arrangement of words ſeems to have been made, than what contributed to its ſweetneſs and facility of utterance.

That the Italian tongue is derived from the vulgar language of the ancient Romans, ſeems the opinion of the beſt critics; but to diſcover and point out by what degrees it was ſmoothed and poliſhed to the ſtate in which Dante, Petrarca, and Boccaccio found it in the fourteeenth century, would require more time, and occupy more ſpace in this article, than the ſubject ſeems neceſſarily to require. However, as the Italian language has been truly allowed to be more muſical in itſelf when merely ſpoken with purity, than any other in Europe, an enquiry into the cauſes of its natural melody and mellifluence does not ſeem foreign to the ſubject of the preſent article.

Muratori (Diſſert. 32.) has given innumerable paſſages from authors of the eighth and ninth centuries, to prove, that after the Franks and Germans were ſettled in Italy, articles were uſed in the Latin language inſtead of pronouns and changes of termination, in order to ſave the trouble of inflecting the caſes in nouns; but pretends not to ſay what this vulgar language was, or whether the clergy preached to the common people, or merchants carried on their correſpondence in Latin or Italian.

The learned Maffei allows the Provençal, French, Spaniſh, and Italian languages, to be deſcendants from the Latin, but denies that the ancient inhabitants of Italy adopted any words from the Goths or Huns who invaded them. The genius of the German, Francic, or Teutonic language, which was ſpoken by the Lombards, was ſo diametrically oppoſite to that of the Italians, that it ſeems incredible there ſhould have been any exchange or union of dialects between them: the one being as remarkable for its numerous conſonants and harſh terminations, as the other for its open vowels and mellifluous endings. As it is the opinion of this profound critic that the Romans had always a vulgar dialect, leſs grammatical and elegant than that of the ſenate and of books, he ſuppoſes the French, Spaniſh, and Italian languages to have been different modifications of this ruſtic, plebeian dialect. But it is as difficult to aſſign a reaſon for all theſe daughters of one common mother being ſo diſſimilar, as it is to account for the little reſemblance that is frequently found between other children of the ſame parents. And why the French language ſhould have ſo many naſal endings, the Spaniſh ſo many ſibillating, and the Italian alone have none but vocal terminations, can only have been occaſioned by ſome particular and radical tendency in the vulgar and plebeian language of each country from very high antiquity.

While this language was forming, no muſic ſeems to have been cultivated in Italy, except the canto fermo of the church; and, unluckily, no written melody can be found to the Canzoni of Dante, the ſonnets of Petrarca, or the ſongs of Boccaccio, the three great founders of the Italian tongue. Yet theſe, we are told, were all ſet to ſome kind of muſic or other, and ſung even in the ſtreets. See the biographical articles of theſe lyric poets, particularly that of Boccaccio; whoſe "Decamerone" has always been regarded as a natural and faithful delineation of the manners and cuſtoms of Italy, at the time when it was written.

With reſpect to muſic, whether the perſonages which he aſſembles together after the plague at Florence 1348, and the ſtories they tell, are real or imaginary, the amuſements he aſſigns them in his ritual muſt have been ſuch as were uſual to the Florentines, among whom he lived at that time; and indeed the poems that are pretended to have been ſung, and the inſtruments with which they were accompanied, ſubſiſted before this period, and ſtill ſubſiſt.

Boccaccio tells us, at the end of his *prima giornata*, or firſt day, that "after ſupper the inſtruments were called in, when the queen, for the day, ordained that there ſhould be a dance; and after one had been led off by Lauretta, Emilia ſung a ſong, in which ſhe was accompanied by Dion, a gentleman of the party, on the lute." There is nothing new or extraordinary in this quotation. But in Italy, whence all the liberal arts have travelled to the reſt of Europe, it is curious to know in what rank muſic was held at this early period, and what uſe was made of it in polite aſſemblies, by the inhabitants. And here a writer, juſtly celebrated for the exactneſs with which he has deſcribed the cuſtoms of his contemporaries in all ſituations, tells us, that in an aſſembly of perſons of birth and education, who paſſed ten days together during ſummer in a conſtant ſucceſſion of innocent amuſements, each evening was cloſed by dance and ſong; in which the whole company, conſiſting of ſeven ladies and three gentlemen, of different characters and acquirements, were able to perform their parts.

When we are told, that the lady who ſang was accompanied by the lute, we know not of what this accompaniment conſiſted, whether it only fortified the voice-part by playing the ſame melody, or more elaborately furniſhed a baſe and a different treble, ariſing out of its harmony.

On the ſecond day we find, that one of the company leading off a carol, a ſong was ſung by another, which was anſwered in a kind of chorus by the reſt.

At the cloſe of the ſecond day Boccaccio tells us, that after the ſong, of which he gives the words, had been performed, many others were ſung, and many dances danced to different tunes, by which we may gather, that beſides carols and ballads, the ſinging of which marked the ſteps of a dance, there were at this time ſongs without dances, and tunes without ſongs.

Whoever reads the hiſtory of the moſt ancient inhabitants of this iſland, the Cambro-Britons, will find innumerable inſtances of the reverence which they paid to ther poet-muſicians, the bards both of Pagan and Chriſtian times; and ſongs of very high antiquity have been preſerved in the Welſh language, though not all the tunes to which they were ſung.

We are told (Miſcel. Antiq. vol. ii. p. 8.) that ſir Thomas Wyatt was the firſt who introduced Italian numbers into Engliſh verſification. This may have contributed to improve our lyric poetry; but to confeſs the truth, from the few parts of the firſt claſs throughout Europe, who, at the beginning of the ſixteenth century, condeſcended to write madrigals and ſongs for muſic, it ſeems that the rage for canon, fugue, multiplied parts, and diſſimilar melodies, moving at the ſame time, had ſo much employed the compoſers, and weaned the attention of the hearers of theſe learned, or, as ſome call them, Gothic contrivances, from poetry, that the words of a ſong ſeem to have been only a pretence for ſinging; and as the poets of the two or three laſt centuries were in little want of muſic, muſicians, in their turn, manifeſted as little reſpect for poetry; for in theſe elaborate compoſitions, the words are rendered utterly unintelligible by repetitions of particular members of a verſe; by each part ſinging different words at the ſame time; and by an utter inattention to accent.

In the "Eſſays on Song-writing," publiſhed with a collection of Engliſh ſongs (we need not name the author, whom he has not named himſelf, nor given the date of the publication) there are many judicious and excellent reflections; and the ſongs are admirably ſelected, and form the beſt collection in our language, under the three following heads: "On Song-writing in general;" "On Ballads and paſtoral Songs;" "On paſſionate and deſcriptive Songs."

We can perceive, however, that the author of theſe ingenious eſſays loves poetry better than muſic; a perſonage whom he does not treat with common civility, when he ſays, "the heroine Poetry muſt give place to the *harlot Muſic*," notwithſtanding her claim to the title of a *lady of faſhion*. But we think the two ladies ſhould *ride and tie*. There are ſongs where the poetry ſhould be reſpected, and the muſic ſubordinate; and others, where muſic is entitled to preeminence.

We wiſh not fine poetry to have fine muſic, nor fine muſic to be manacled by laboured poetry. Lyric poetry cannot be too ſimple.

The author allows the primitive meaning of a ſong to ſignify ſomething to be *ſung:* and when he ſays, "a ſong, as a poetical compoſition, may be defined a ſhort piece, divided into returning portions of meaſures, and formed upon a ſingle incident, thought, or ſentiment," we readily ſubſcribe to the definition. Indeed it was our opinion, (ſee Italian Tour,) long before we had the pleaſure to peruſe theſe well written eſſays; and it is an opinion to which Metaſtaſio has conſtantly adhered, in all his admirable muſical dramas.

With regard to paſtoral ſongs, though the Sicilian paſtoral is not natural to our climate, yet we produce better fruit for the table in our hot-houſes, than the ſouthern continent of Europe can boaſt. An opera ſong is a *hot-houſe* plant. Paſtoral ſongs may have paſtoral muſic, as the Siciliana movement has been happily treated more frequently by Handel, and many of our beſt national compoſers, ſuch as Arne and Boyce, than any other. And as for ſimple ballad tunes for hiſtorical and narrative ſongs, and common ditties, there can be no ſcarcity; as a collector of our acquaintance, many years ago, had amaſſed a ſufficient number of ſongs ſet to muſic, and printed on a ſingle folio half-ſheet, from the latter end of the 17th century, to fill twelve volumes.

For deſcriptive and paſſionate ſongs, we have pictureſque and paſſionate muſic; and we hope this intelligent and elegant writer will allow the *lady Muſic* to be tricked out a little in paſſionate and deſcriptive ſongs. Haydn, in his "Seaſons," has deſcribed very happily, we think, rural ſports and occupations, and admirably diſplayed her imitative and picturesque powers, in awakening ideas of the ſeveral ſeaſons, and the ruſtic employments of each.

Spring.

The overture paints the departure of winter, and approach of ſpring; ploughing, ſowing; a prayer to heaven for proſperity; the youths and virgins going a Maying; chorus of thanks to the Supreme Being, in which is an admirable fugue, equal to the beſt vocal fugues of Handel.

Summer.

The overture paints the dawn of day; the riſing ſun; choral hymn to that luminary; mowing, reaping; a ſhady retreat; rural employments, and evening ſports.

Autumn.

The ſymphony indicates the huſbandman's ſatisfaction at his plentiful harveſt; chorus in praiſe of induſtry and labour; fruits gathered; duet between an innocent fond pair; field ſports; hunting; vintage; dancing; romping; ſinging; revelling, and jubilation.

Winter.

The overture paints thick fogs at the approach of winter; horrors of winter; diſtreſs of travellers; evening domeſtic amuſements; purring of the wheel; a narrative ruſtic ſong; moral reflections on winter, ſet to a fine air, cantabile; future rewards of a life well ſpent, in the coro finale.

Milton's Allegro and Penſeroſo, as ſet by Handel, which are all *deſcription,* have not been injured by too elaborate muſic; but theſe are not the ſongs nor the muſic of which we meant to trace the hiſtory, when we began the preſent article. See Air.

Song *of Birds,* is defined by the Hon. Daines Barrington to be a ſucceſſion of three or more different notes, which are continued without interruption, during the ſame interval, with a muſical bar of four crotchets in an adagio movement, or whilſt a pendulum ſwings four ſeconds.

It is obſerved that notes in birds are no more innate than language in man, and that they depend entirely upon the maſter under which they are bred, as far as their organs will enable them to imitate the ſounds which they have frequent opportunities of hearing: and their adhering ſo ſteadily, even in a wild ſtate, to the ſame ſong, is owing entirely to the neſtlings attending only to the inſtruction of the parent-bird, whilſt it diſregards the notes of all others that may perhaps be ſinging round him.

Birds in a wild ſtate do not commonly ſing above ten weeks in the year, whereas birds, that have plenty of food in a cage, ſing the greateſt part of the year: and we may add, that the female of no ſpecies of birds ever ſings; and this is a wiſe proviſion of nature, becauſe her ſong would diſcover her neſt; and, in the ſame manner, we may rationally account for her inferiority in reſpect to plumage. The faculty of ſinging is confined to the cock birds; and accordingly Mr. Hunter, in diſſecting birds of ſeveral ſpecies, found the muſcles of the larynx to be ſtronger in the nightingale than in any other bird of the ſame ſize; and in all thoſe inſtances, where he diſſected both cock and hen, the ſame muſcles were ſtronger in the cock. To the ſame purpoſe, it is an obſervation as ancient as the time of Pliny, that a capon does not crow.

Some have aſcribed the ſinging of the cock-bird in the ſpring to the motive only of pleaſing his mate, during incubation; nature, indeed, partly for this end, has given to the male the power of ſinging: but the ſinging of a bird in the ſpring is more probably owing to the greater plenty of plants and inſects, which, as well as ſeeds, are the proper food of ſinging birds, at that time of the year.

Mr. Barrington remarks, that there is no inſtance of any bird's ſinging, which exceeds our black-bird in ſize; and this, he ſuppoſes, may ariſe from the difficulty of its concealing itſelf, if it called the attention of its enemies, not only by bulk, but by the proportionable loudneſs of its notes. This writer farther obſerves, that ſome paſſages of the ſong, in a few kinds of birds, correſpond with the intervals of our muſical ſcale, of which the cuckoo is a ſtriking and known inſtance; but much the greater part of ſuch ſong is not capable of muſical notations: partly, becauſe the rapidity is often ſo great, and it is alſo ſo uncertain when they may ſtop, that we cannot reduce the paſſages to form a muſical bar in any time whatſoever; partly alſo, becauſe the pitch of moſt birds is conſiderably higher than the moſt ſhrill notes of thoſe inſtruments which comprehend even the greateſt compaſs; and principally, becauſe the intervals uſed by birds are commonly ſo minute, that we cannot judge at all of them from the more groſs intervals into which we divide our muſical octave. This writer apprehends, that all birds ſing in the ſame key; and in order to diſcover this key he informs us, that the following notes have been obſerved in different birds, A, B flat, C, D, F, and G; and, therefore, E only is wanting to complete the ſcale: now theſe intervals, he ſays, can only be found in the key of F with a ſharp third, or that of G with a flat third; and he ſuppoſes it to be the latter, becauſe, admitting that the firſt muſical notes were learned from birds, thoſe of the cuckoo, which have been moſt attended to, form a flat third; and moſt of our compoſitions are in a flat third, where muſic is ſimple, and conſiſts merely of melody. As a farther evidence, that birds ſing always in the ſame key, it has been found by attending to a nightingale, as well as a robin, which was educated under him, that the notes reducible to our intervals of the octave were always preciſely the ſame.

Moſt people, who have not attended to the notes of birds, ſuppoſe, that thoſe of every ſpecies ſing exactly the ſame notes and paſſages, which is by no means true, though it is admitted that there is a general reſemblance. Thus the London bird-catchers prefer the ſong of the Kentiſh goldfinches, and Eſſex chaffinches; but ſome of the nightingale-fanciers prefer a Surrey bird to thoſe of Middleſex.

The nightingale has been almoſt univerſally reckoned the moſt capital of ſinging birds; and its ſuperiority, deduced from a caged bird, conſiſts in the following particulars: its tone is much more mellow than that of any other bird, though at the ſame time, by a proper exertion of its muſical powers, it can be exceſſively brilliant. Another point of ſuperiority is its continuance of ſong, without a pauſe, which is ſometimes no leſs than twenty ſeconds; and when the reſpiration became neceſſary, it has been taken with as much judgment as by an opera-ſinger. The ſky-lark in this particular, as well as in compaſs and variety, is only ſecond to the nightingale. The nightingale alſo ſings, if the expreſſions may be allowed, with ſuperior judgment and taſte. Mr. Barrington has obſerved, that his nightingale, which was a very capital bird, began ſoftly like the ancient orators; reſerving its breath to ſwell certain notes, which by this means had a moſt aſtoniſhing effect. This writer adds, that the notes of birds, which are annually imported from Aſia, Africa, and America, both ſingly and in concert, are not to be compared to thoſe of Europe.

The following table formed by Mr. Barrington, agreeably to the idea of M. de Piles in eſtimating the merits of painters, is deſigned to exhibit the comparative merit of the Britiſh ſinging birds: in which twenty is ſuppoſed to be the point of abſolute perfection.

	Mellowneſs of tone.	Sprightly notes.	Plaintive notes.	Compaſs.	Execution.

See Phil. Tranſ. vol. lxiii. pt. ii. art. 31. p. 249, &c.

Song, *Reſponſary*. See Responsary.

SONGARI, in *Geography*, a river of Chineſe Tartary, which joins the Amur at Saghalien.—Alſo, a town of Chineſe Tartary; 10 miles N.W. of Foe Petouné Hotun.

SONGEONS, a town of France, in the department of the Oiſe, and chief place of a canton, in the diſtrict of Beauvais; 12 miles N.W. of Beauvais. The place contains 1041, and the canton 12,577 inhabitants, on a territory of 205 kiliometres, in 29 communes.

SONG-HOA, a town of Corea; 50 miles S.W. of Hoang.

SONGI, a river of Malacca, which runs into the Chineſe ſea, N. lat. 2° 10′. E. long. 104° 10′.

Songi *Tanjang*, a town on the weſt coaſt of the iſland of Sumatra. N. lat. 2° 35′. E. long. 97° 10′.

SONGIEU, a town of France, in the department of the Ain; 13 miles N. of Belley.

SONG-KI, a town of China, of the third rank, in Fo-kien; 40 miles N.N.E. of Kien-nhing.

SONG-KIANG, a city of China, of the firſt rank, in Kiang-nan, ſituated in the midſt of ſeveral rivers or canals, near the ſea, ſo that the Chineſe junks approach it in every direction. It carries on a large trade in cotton cloth, which the inhabitants ſend to different parts of the empire. It has four towns in its juriſdiction; 560 miles S. of Peking. N. lat. 31°. E. long. 120° 44′.

SONG-MEN-CHAN, a ſmall iſland, near the coaſt of China, in Tche-kiang. N. lat. 28° 22′. E. long. 121° 21′.

SONGO, or Sango, a town of Africa, in the kingdom of Mandingo, near the coaſt of the Gambia.

Songo. See Sankari and Sogno.

SONGOA, an iſland in the ſtraits of Malacca, about 50 miles in circumference. N. lat. 2° 18′. E. long. 100° 30′.

SONGOO, a ſmall iſland in the Indian ſea, near the coaſt of Africa. S. lat. 7° 20′.—Alſo, a town on the eaſt coaſt of the iſland of Banca. S. lat. 2° 12′. E. long. 106° 16′.

SONGORA. See Sangora.

SONG-TCHOUI, a town of China, of the third rank, in Hou-quang; 40 miles N.E. of Ou-tchang.

SONG-TSI, a town of China, of the third rank, in Hou-quang; 27 miles W. of King-tcheou.

SONG-YANG, a town of China, of the third rank, in Tche-kiang; 22 miles W. of Tchu-tcheou.

SONGY-DAVAN, a town on the weſt coaſt of Sumatra. N. lat. 1° 18′. E. long 98° 12′.

SONGY-LAMA, a town on the weſt coaſt of Sumatra. S. lat. 3° 40′. E. long. 101° 57′.

SONHO, Songo, or *Sogno*. See Sogno.

SON-HOIT, a diſtrict of Chineſe Tartary, in the territory of the Mongols. N. lat. 42° 48′. E. long. 114° 27′.

SONKOE, a town of Bengal; 15 miles W.N.W. of Moorſhedabad.

SONMEANY, the principal ſea-port in the diſtrict of Lus, and province of Mekran, in Perſia. It is a ſmall and mean town, and was deſtroyed in 1809 by the Jouaſſimees. It is ſituated on an elevated bank, at the mouth of the river Pooralee, which forms a bar about a mile from the town, three fathoms deep at low-water, and boats can anchor cloſe to the ſhore. The inhabitants, with the exception of a few Hindoo merchants, live chiefly by fiſhing. Freſh water is procured by digging in the ſand: and it is neceſſary that the well be immediately filled up; for if it be ſuffered to remain open, the water becomes ſalt.

SONNA, a book, or collection of the Mahometan traditions, or of the ſayings and actions of their prophet, which all the orthodox Muſſulmen are required to believe. This is a kind of ſupplement to the Koran, directing the obſervance of ſeveral things omitted in that book, and in ſenſe, as well as deſign, correſponding to the Miſhna of the Jews. See Mahometanism.

The word ſignifies, in Arabic, the ſame with *miſhna* in the Hebrew, that is, *ſecond law;* or, as the Jews call it, *oral law*.

The adherents to the Sonna are called *Sonnites*, or *Traditionaries;* and as, among the Jews, there is a ſect of Caraites, who reject the traditions as fables invented by the rabbins; there are alſo ſectaries among the Mahometans, called *Schiites*, (ſee the article,) who reject the traditions of the Sonnites, as being only founded on the authority of an apocryphal book, and not derived to them from their legiſlator.

There is the ſame enmity between the Sonnites and Schiites, as between the rabbiniſt Jews and the Caraites. The Schiites reproach the Sonnites, with obtruding the dreams of their doctors for the word of God; and the Sonnites, in their turn, treat the Schiites as heretics, who refuſe to admit the divine precepts, and who have corrupted the Koran, &c.

The Sonnites are ſubdivided into four chief ſects, which, notwithſtanding ſome differences as to legal concluſions in their interpretations of the Koran, and matters of practice, are generally acknowledged to be orthodox in radicals or matters of faith, and capable of ſalvation; and have each of them their ſeveral ſtations or oratories in the temple of Mecca. The founders of theſe ſects are regarded as the great maſters of juriſprudence, and are ſaid to have been men of great devotion and ſelf-denial, well verſed in the knowledge of thoſe things which belong to a future life, and to man's right conduct in the preſent ſtate, and directing all their knowledge to the glory of God. This is Al Ghazeli's encomium of them, who thinks it derogatory to their honour, that their names ſhould be uſed by thoſe who, neglecting to imitate the other virtues which form their character, apply themſelves merely to attain their ſkill, and follow their opinions in matters of legal practice.

The firſt of theſe orthodox ſects is that of the “Haneſites,” ſo named from their founder, Abu Hanifa al Nomen Ebn Thebet, who was born at Cufâ, in the 80th year of the Hegira, and died in the 150th; ending his life in priſon, at Bagdad. The reaſon of his confinement was his refuſal to be called “Kadi,” or judge; and when he was queſtioned concerning it, he is ſaid to have replied, “If I ſpeak the truth, I am unfit; but if I tell a lie, a liar is not fit to be a judge.” It is reported, that, during his confinement in priſon, he read over the Koran no leſs than 7000 times. An Arabian writer calls the Hanefites “the followers of reaſon,” and thoſe of the three other ſects “followers of tradition;” the former being principally guided by their own judgment in their deciſions, and the latter adhering more tenaciouſly to the traditions of Mahomet. This ſect formerly obtained chiefly in Irak, but now generally prevails among the Turks and Tartars. The ſecond orthodox ſect is that of Malec Ebn Ans, who was born at Medina, in the year of the Hegira 90, 93, 94, or 95; and died there in 177, 178, or 179. This doctor is ſaid to have paid great regard to the traditions of Mahomet. In his laſt illneſs, a friend who viſited him, and found him in tears, and aſking the reaſon of it, received for anſwer, “How ſhould I not weep? and who has greater reaſon to weep than I? Would to God that for every queſtion decided by me according to my opinion, I had received ſo many ſtripes! then would my account be more eaſy. Would to God I had never given any deciſion of my own!” The doctrine of Malec is chiefly favoured in Barbary, and other parts of Africa. The third orthodox ſect was denominated “Shafeites.” (See the article.) The founder of the fourth ſect was Ahmed Ebn Hanbal. See HANBAL. Sale's Koran, Int.

SONNEBECK, in *Geography*, a town of France, in the department of the Lys; 5 miles N.E. of Ypres.

SONNEBERG, a town of Bohemia, in the circle of Saatz; 6 miles W. of Commotan.—Alſo, a town of Germany, in the principality of Coburg; 10 miles N.N.E. of Coburg. N. lat. 50° 23′. E. long. 11° 13′.—Alſo, a town of Auſtria; 12 miles S.S.W. of Laab. N. lat. 48° 29′. E. long. 16° 2′.—Alſo, a citadel of Auſtria, which gives name to a county veſted in the houſe of Auſtria; 23 miles S. of Bregentz.

SONNEBORN, a town of Pruſſia, in the province of Oberland; 5 miles S. of Morungen.

SONNEBURG, a town of the Middle Mark of Brandenburg, on a ſmall river, which runs into the Warta; in which is a commandery of the knights of Malta. The grand-maſter may create as many knights as he pleaſes, nor are Lutherans excluded, who are permitted to marry. The elector of Brandenburg is the grand-maſter of the order; 10 miles E.S.E. of Cuſtrin. N. lat. 52° 37′. E. long. 14° 58′.

SONNECQUE, a river of Brabant, which runs into the Senne, 5 miles above Halle.

SONNEG, a town of the duchy of Carinthia; 2 miles S. of Eberndorff.

SONNEN KOGEL, a mountain of Auſtria; 8 miles S. of Steyr.

SONNENBERG, a town of Germany, in the principality of Naſſau Saarbruck Uſſingen; 2 miles N.E. of Wiſbaden.—Alſo, a town of Sileſia, in the principality of Grotkau; 6 miles S.E. of Grotkau.—Alſo, a town of Pruſſia, in the province of Bartenland; 12 miles S.E. of Bartenſtein.—Alſo, a town of Pruſſia, in the province of Ermeland; 16 miles E.N.E. of Elbing.

SONNENBURG, a town of Brandenburg, in the New Mark, on the Lenza; 7 miles E. of Cuſtrin. N. lat. 52° 37′. E. long. 14° 58′.

SONNENSTEIN, a fortreſs of Saxony, in the margraviate of Meiſſen, near Pirna.

SONNERATIA, in *Botany*, was ſo named by the younger Linnæus, in honour of a diſtinguiſhed French traveller and naturaliſt, M. Sonnerat, who publiſhed, in 1776, a Voyage to New Guinea, in one volume. 4to.; and in 1782, a Voyage to the Eaſt Indies and China, in two ſimilar volumes. Both works are adorned with a multitude of engravings. They do honour to the author's character, as well as to his information. The latter publication is peculiarly inſtructive and correct, on the ſubject of Hindoo mythology, and has been made much uſe of by various ſucceeding writers. Botany does not make a prominent part of M. Sonnerat's performances; but he has deſcribed and figured ſeveral new or rare plants, particularly adverting to important articles of trade or medicine whoſe hiſtory was previouſly obſcure, in his Voyages, and he is alſo the author of ſome expreſsly botanical treatiſes, of ſimilar aim, which have been given to the world in periodical publications. He died, a ſhort time ſince, at an advanced age, having juſt before paid a viſit to England.—Linn. Suppl. 38. Schreb. Gen. 337. Willd. Sp. Pl. v. 2. 999. Mart. Mill. Dict. v. 4. Juſſ. 325. Lamarck Illuſtr. t. 420. (Aubletia; Gærtn. t. 78.)—Claſs and order, *Icoſandria Monogynia*. Nat. Ord. *Myrti*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coriaceous, ſomewhat bell-ſhaped at the baſe, with a tumid internal border; the limb in ſix or four ovate, acute, ſpreading, flat, permanent ſegments. *Cor.* Petals ſometimes ſix, awl-ſhaped, ſpreading, inſerted into the internal rim of the calyx, and about the ſame length; in ſome caſes wanting. *Stam.* Filaments numerous, flattened, inſerted likewiſe into the rim of the calyx, as long or longer than its ſegments; anthers roundiſh. *Piſt.* Germen ſuperior, globoſe, ſtyle thread-ſhaped, about the length of the ſtamens; ſtigma capitate. *Peric.* Berry large, globoſe, pointed, ſmooth, ſeated on the permanent calyx, of many cells, full of veſicular pulp. *Seeds* numerous, oblong, curved, gibbous and corrugated.

Eſſ. Ch. Calyx in four or ſix ſegments, coriaceous, inferior, permanent. Petals awl-ſhaped, or none. Berry of many cells. *Seeds* numerous, gibbous.

Obſ. This genus is ſomewhat like a *Punica*, with its fruit turned out of the calyx. The younger Linnæus ſeems to have ſtudied very ſuperficially the only ſpecies which fell in his way, never perceiving it to be an old plant of his father's, deſcribed and figured by Rumphius.

1. S. *acida*. Red-flowered Sonneratia. Linn. Suppl. 252. Willd. n. 1. (Rhizophora caſeolaris; Linn. Sp. Pl. 635. Aubletia caſeolaris; Gærtn. v. 1. 379, excluding the ſynonym of Rumphius. Mangium caſeolare rubrum; Rumph. Amboin. v. 3. 112. t. 74. Pagapate; Sonner. Nouv. Guin. 16. t. 10, 11.)—Flowers in ſix ſegments; with ſix petals. Leaves elliptic-oblong. Branches quadrangular.—Native of the muddy banks of large rivers in the Molucca iſlands; often planted about houſes for the ſake of its fruit. Sonnerat found it in moiſt parts of New Guinea. We have a ſpecimen, gathered by Dr. Buchanan in Bengal, where, as he informs us, the natives know this plant by the name of *Duabanga*. The Malays call it *Brappat*, according to Rumphius, who deſcribes it as a large tree, flowering in

October. The *branches*, as he juſtly obſerves, are ſquare, not round. The heart of the *wood* is hard and durable. *Leaves* oppoſite, on very ſhort ſtalks, elliptic-oblong, obtuſe, with a ſmall point, entire, ſomewhat ſucculent, a ſpan long, ſmooth, with one rib, and numerous tranſverſe veins; their under ſide glaucous. *Flowers* terminal, ſolitary, of a beautiful red. *Fruit* green, acid, ſmelling like rotten cheeſe, falling out of the *calyx* when quite ripe. The Malays, &c. eat it, as well as the young leaves, with fiſh and other food. The beautiful half-expanded *flowers* are worn as ornaments for the head, and are often imitated in gold. Rumphius ſays it is uſual to depreſs the ſtamens with two little pegs, forced croſs-wiſe through the piſtil.

2. S. *alba*. White-flowered Sonneratia. (Mangium caſeolare album; Rumph. Amboin. v. 3. 111. t. 73.)—Flowers in ſix, or more, ſegments, without petals? Leaves elliptical or roundiſh. Branches round.—Native of ſtony or rocky plains, overflowed by the tide, on the ſea-ſhore of the Molucca and neighbouring iſlands, flowering in Auguſt and September. Rumphius deſcribes this as a large, thick and rugged *tree*, like an oak, with ſpreading and curved branches, commonly laden with various paraſitical plants. The *branches* are round. *Leaves* ſmooth, brittle and ſucculent, with hardly any viſible veins, and of a rounder broader ſhape than the foregoing. *Flowers* two or three together at the end of each branch. *Calyx* green, in ſix, ſeven or eight diviſions. No mention is made of any *petals*. *Stamens* long, white, with brown *anthers*. *Style* very long, with a green *ſtigma*. *Fruit* depreſſed, as broad as the hand, internally dry, white, and granular, with an aſtringent, and ſlightly acid flavour, but no ſmell. It burſts at length into ſeveral portions, but does not fall off like the former, nor is it ſo generally eaten, except when dreſſed with fiſh. Rumphius ſo clearly diſtinguiſhes this ſpecies, which Gærtner miſtook for the former, and Linnæus confounded therewith under his *Rhizophora caſeolaris*, that though we have ſeen no ſpecimen, we have ventured to deſcribe it. What thoſe horn-ſhaped excreſcences are, which occupy the ſoil at ſome diſtance from the baſe of this tree, from a ſpan to a foot in length, and of a corky ſubſtance, as deſcribed by Rumphius, we can offer no conjecture.

3. S. *apetala*. Small-flowered Sonneratia. Buchanan in Symes's Embaſſy to Ava, octavo, v. 3. 313. t. 25.—Flowers in four ſegments; without petals. Leaves ovato-lanceolate. Branches round, pendulous.—Native of the moiſt inundated ſea-ſhores of the kingdom of Ava, near Rangoon, flowering in May. We have ſpecimens communicated by Dr. Roxburgh to lord Valentia. This is deſcribed as a moſt beautiful *tree*, reſembling our Weeping Willow, but taller, with ſcattered, pendulous, ſmooth, round, ſlender branches. *Leaves* few, oppoſite, ſtalked, ovato-lanceolate, entire, ſmooth, rather fleſhy, about three inches long, moſtly blunt, a little unequal at the baſe, hardly an inch broad. *Flowers* axillary and terminal, ſtalked, drooping, greeniſh, about an inch in diameter, with white ſtamens, the length of the *calyx*, but no *petals*. *Fruit* orbicular, depreſſed, of eight cells, with numerous angular *ſeeds*. The *ſtigma* is remarkable for its great ſize, and conical figure, hollow underneath, like a ſort of cap. The want of *petals* in this ſpecies induces us the more readily to believe, that they may alſo be wanting in the laſt, and that the accurate Rumphius has not merely by accident omitted to mention them.

SONNERSKARET, in *Geography*, a ſmall iſland on the E. ſide of the gulf of Bothnia. N. lat. 63° 25′. E. long. 21° 32′.

SONNET, Sonetto, in *Poetry*, a kind of compoſition properly contained in fourteen verſes; *viz.* two ſtanzas, or meaſures, of four verſes each, and two of three; the eight firſt verſes being all in two rhymes.

The ſonnet is of Italian origin, and Petrarch is allowed to be the father of it; it is held the moſt difficult and artful of all poetical compoſitions, as requiring the utmoſt accuracy and exactneſs. It is to end with ſome pretty ingenious thought: the cloſe muſt be particularly beautiful, or the ſonnet is defective.

In Malherb, and ſome other French poets, we meet with ſonnets, where the two firſt ſtanzas are not in the ſame rhyme; but they are held irregular; and, in effect, great part of the merit of theſe pieces conſiſts in a ſcrupulous obſervance of the rules.

Ronſard, Malherb, Maynard, and Gombaut, have compoſed abundance of ſonnets; but, among two or three thouſand, there are ſcarcely two or three worth much.

Paſquier obſerves, that Du Bellai was the firſt who introduced ſonnets into France. But Du Bellai himſelf ſays, that Merlin de S. Gelais firſt converted the Italian ſonnets into French.

Of twenty-three ſonnets which were written by our great poet Milton, that addreſſed to Henry Laws is one of the beſt; and yet this ſhews how difficult and unnatural the conſtruction of this ſpecies of poem is in the Engliſh language; whereas, from the great number of ſimilar terminations in the Italian tongue, and the ſucceſs of Petrarch, it has long been the favourite meaſure of Italy for ſhort compoſitions. However, Muratori thinks it extremely difficult for his countrymen to make a good ſonnet; and he compares this kind of poem to the bed of Procruſtes, where the legs of thoſe that were too ſhort were ſtretched, and thoſe too long were cut to the ſize of the bed.

Antonio a Tempo, a civilian at Padua, in his Treatiſe on Poetry, 1332, diſtinguiſhes ſixteen different kinds of ſonnet. Burney's Hiſt. Muſic, vol. ii. p. 324.

SONNEWALDE, in *Geography*, a town of Saxony; 10 miles S. of Luckau. N. lat. 51° 40′. E. long. 13° 38′.

SONNINO, a town of Campagna di Roma; 6 miles N. of Terracina.

SONNO, a town of Japan, in the iſland of Niphon; 18 miles N.W. of Iwata.

SONOKI, a town of Mingrelia; 45 miles S.E. of Anarghia.

SONORA, or Senora, a province of New Spain, ſituated between 35° and 27° N. lat. and 110° and 117° W. long.; bounded N. by New Mexico, W. by California, S. by Sinaloa and the gulf, and E. by Biſcay and New Mexico. Its greateſt length from N. to S. is about 420 miles, and its breadth from E. to W. 380 miles. The air is dry and pure, and the climate generally healthy, though near the gulf the ground is marſhy, and it is, in ſome of the diſtricts, inſalubrious. Sonora abounds in rich gold and ſilver-mines, particularly the former. Like Biſcay, it is deſtitute of timber, but it has ſome rich ſoil near the gulf. Its rivers are the Rio de l'Aſcenſion, which enters the gulf of California about N. lat. 31°, and the Rio Yaqui, which diſcharges itſelf into the ſame gulf at Guyamas, at N. lat. 28°. Its animals are the deer, cabrie, and bear, and large lizards, which are tamed by the inhabitants, and trained to catch mice. The population of Sonora may be eſtimated at 200,000 ſouls, conſiſting of Spaniards, Creoles, Metiſs, and Indians. The capital of Sonora is Ariſpaa, ſituated in N. lat. 21° and W. long. 111°, near the head of the river Yaqui; celebrated for the urbanity and hoſpitality of its inhabitants,

habitants, and for the large quantity of gold table utenſils uſed in their houſes; and having a population of 3400 perſons. The next cities in reſpect of magnitude are Sonora, S., and Terenate, N. of the capital. Sonora trades with New Mexico and Biſcay for the productions of thoſe different provinces, and with old Mexico, both by land and ſea, through the gulf of California. It is famous for its cheeſe, horſes, and ſheep. The governor is a brigadier-general, and his ſalary is 7000 dollars, in addition to his pay in the line. The regular military force of this province conſiſts of 900 dragoons, and 200 infantry, the latter being Indians called Opejas, and reckoned the beſt ſoldiers in New Spain. The profeſſed religion is the Catholic, and it belongs to the dioceſe of the biſhop of Durango. The ſeat of government is at Chihuahua.

SONORYA, a town of Hindooſtan, in Benares; 10 miles S. of Merzapour.

SONS HARMONIQUES, or fluted ſounds, a ſingular kind of ſound produced on the violin, tenor, and violoncello, by touching the ſtring ſlightly in its aliquot parts and harmonic diviſions, without preſſing the finger on the finger-board; by which means, that part of the ſtring ſounds, which is above the hand next to the nut, not the part touched by the bow. Theſe ſounds are very different in quality of tone from thoſe which would be produced, if the finger were preſſed down. As to the pitch of tone, the harmonics will give the fifth, when the third would be produced by the uſual means; the third, when the ſixth is expected, &c. The quality of tone acquired by this means is ſo much more ſweet than the common tones of the inſtrument, that the French have entitled them *notes flutées*, fluted notes. Rouſſeau ſays, that to form an accurate idea of theſe ſounds, it was neceſſary to hear Mondonville produce them on his violin, and Bernard on his violoncello, who could form a regular ſcale of theſe ſweet tones, which very much aſtoniſhed thoſe who did not know the theory. But we have heard Salomon perform this feat, this trick of youth, with a dexterity and taſte unknown to Mondonville.

As the principle on which this theory is founded depends on transferring the tone, produced by the bow, to that part of the ſtring next the nut, inſtead of that next the bridge, of which the bow prevents the vibration, the long diviſion of the ſtring, when touched ſlightly by the finger, ſeems to produce the higheſt note; and *è contra*.

We ſhall give, in the *Muſic Plates*, a table of harmonic ſounds, which will facilitate the practice of this ſeemingly eccentric ſcale. The firſt line, or ſtaff, will indicate the ſounds which would be produced in the common way; and the ſecond line, the correſpondent fluted note, when the ſtring is touched harmonically. All the ſounds of the trumpet marine are harmonics, which renders it difficult to produce certain ſounds upon that inſtrument. See NOISE.

SONSBECK, in *Geography*, a town of the duchy of Cleves; 11 miles S.S.E. of Cleves.

SONSECA, a town of Spain, in New Caſtile; 8 miles S. of Toledo.

SONSINO. See SONCINO.

SONSONATE. See *La* TRINIDAD.

SONTAG, a town of the duchy of Stiria; 3 miles N.W. of Fridau.

SONTAGBERG, a town of Auſtria, in which is a cloiſter of Benedictines; 5 miles N. of Bavarian Waidhoven.

SONTAGE, in our *Old Writers*, a tax of forty ſhillings laid upon every knight's fee, according to Stow, p. 284.

SONTHEIM, in *Geography*, a town of Germany, in the lordſhip of Limburg; 15 miles S.E. of Hall in Swabia.

SONTHEIM, *Maine*, a town of the duchy of Wurzburg, on the Maine; 3 miles N. of Kitzingen.

SONTHOFEN, or SUNTHOFEN, a town of Bavaria, in the biſhopric of Augſburg; 56 miles S. of Augſburg.

SONTHONNAX *de la Montagne*, a town of France, in the department of the Ain; 6 miles N.W. of Nantua.

SONTRA, a town of Germany, in the principality of Heſſe Rhinfens, on the Wohra; 28 miles S. of Caſſel. N. lat. 51° 5′. E. long. 9° 58′.

SONVICO, a town of Italy; 5 miles N. of Lugano.

SONUS, or NUMADUS, in *Ancient Geography*, a river of India, on this ſide of the Ganges, which had its ſource in the mountains, ran towards the eaſt, and bending its courſe towards the north-eaſt, diſcharged itſelf into the Ganges, a little below Jomanas, after a courſe of about 200 leagues. M. d'Anville ſuppoſes that this river is the Audomatis of Arrian; but as this river had its riſe among the Mondiadini, and ran into the Ganges, it could not be the ſame with the Sonus.

SONWARY, in *Geography*, a town of Hindooſtan, in Guzerat; 21 miles S. of Surat.

SONZAY, a town of France, in the department of the Indre and Loire; 12 miles N. of Tours.

SOO, a town of Japan, in the iſland of Ximo; 25 miles N.W. of Uxumi.

SOOBARUM, a town of Hindooſtan, in the circar of Cicacole; 10 miles N.W. of Viſigapatam.

SOOBKA, a town of Bengal; 13 miles S. of Boglipour.

SOOBOO, a town of Africa, in Bambarra; 10 miles W. of Sego.

SOOBRUDOOKI, a town of Africa, in Bondou; 20 miles S.W. of Fatteconda.

SOO-CHOO. See SOU-TCHEOU.

SOOCOO, in *Commerce*, a money of account at Bencoolen; 4 ſoocoos being = a dollar = 32 ſattalies, or ſatellers: this dollar is reckoned at 5*s.* ſterling.

SOODEREH, in *Geography*, a town of Hindooſtan, in Lahore; 15 miles N.N.E. of Ameenabad.

SOOE, a town of Hindooſtan, in Guzerat; 37 miles N.N.E. of Radunpour.

SOOHA, a town of Africa, in Bambarra, on the river Niger. N. lat. 13° 10′. W. long. 4° 52′.

SOOHAGEE, a town of Hindooſtan, in Boggilcund; 30 miles N.N.E. of Rewah.

SOOINS, a name given in the North to a kind of rural food, that has been found very beneficial in the ſcurvy. This food is prepared by putting ſome oatmeal into a wooden veſſel, and pouring hot water upon it, and continuing the infuſion till the liquor begins to taſte ſouriſh, *i. e.* till a fermentation comes on, which in a place moderately warm may be in the ſpace of two days. The water is then poured off from the grounds, and boiled down to the conſiſtence of a jelly.

SOOKA, in *Geography*, a town of Bengal; 42 miles W. of Silhet.

SOOKANG, a town of Africa, in Fooladoo. N. lat. 13° 35′. W. long. 8° 5′.

SOOKAPOORA, a kingdom of Japan.

SOOKJURAH, a town of Bengal; 33 miles W. of Nagore.

SOOKSOR, a town of Bengal; 6 miles N. of Calcutta.

SOOLARAM, a town of Hindooſtan, in the circar of Ellore.

SOOLOO, one of the Philippine iſlands, in the Eaſt Indian ſea, about 30 miles long and 10 broad, and containing 60,000 inhabitants, who are Malays, governed by a king or ſultan, with an ariſtocracy of about fifteen nobles, named "datoos," who form the greateſt part of the legiſlature, whoſe title is hereditary to the eldeſt ſon, and who ſit in council with the ſultan. This iſland enjoys a perpetual ſummer, and produces a great variety of fruit: it abounds with the tree called teak. Many Chineſe live on the iſland, and carry on great trade, ſending to Canton black and white ſwallows, wax, pearls, teepye, or pearl oyſter-ſhells, bird's-neſts, tortoiſe-ſhell, ſago, rattans, ſandal, and various dyeing woods, cinnamon, or caſſia, &c. At Sooloo, and many neighbouring iſlands, the pearl fiſhery has been carried on for ages, and is the principal ſource of their wealth. The dominions of Sooloo extend over the principal part of the archipelago of iſlands between Borneo and Mindanao, called the Sooloo Archipelago, and even on the north coaſt of the former iſland. Their religion is Mahometan, but in their morals they are faithleſs and cruel. The Engliſh Eaſt India company have an agent in this iſland. On the neighbouring ſea are ſome excellent pearl fiſheries; and abundance of edible bird-neſts are found, eſpecially in a ſmall iſland, or rock, to the S.W. of Sooloo; but the principal production is ſago. The ſituation is between Borneo and Mindanao, 42 miles S.W. from the latter. N. lat. 6°. E. long. 119°.

Sooloo *Archipelago*, a part of the Eaſtern Indian ſea, covered with a great number of ſmall iſlands, extending from the S.W. coaſt of Mindanao to the N.E. coaſt of Borneo.

SOOMA, a town of Japan, in the iſland of Niphon; 45 miles E. of Jedo.

SOOMGONG, a town of Hindooſtan, in Goondwana; 10 miles S. of Nagpour.

SOOMOONANG, a lofty range of mountains, which forms the boundary of Thibet on the ſouth, and divides it from Bootan.

SOONABATTY, a town of Hindooſtan, in Bahar; 40 miles E. of Doeſa.

SOONAJURA, a town of Hindooſtan, in Bengal; 50 miles W. of Silhet.

SOONAL, a town of Hindooſtan, in the country of Malwa, of conſiderable extent, of a ſquare form, and incloſed within a ſtone wall. Two wide ſtreets croſs one another, at right angles, in the middle of the town, which is the "Chowk." There are 32 villages in this pergunnah.

SOONAM, or Sunnam, a town of Hindooſtan, in the country of Delhi; 136 miles W.N.W. of Delhi. N. lat. 29° 57′. E. long. 75° 31′.

SOONAMOOKY, a town of Bengal; 13 miles N. of Biſſunpour. N. lat. 23° 18′. E. long. 87° 33′.

SOONDA, a ſmall country of Hindooſtan, near the weſt coaſt, between Canara and Concan, about 40 miles from north to ſouth, and 30 from eaſt to weſt. After the death of Tippoo, ſultan of Myſore, this country was aſſigned to the Mahrattas.

SOONGARES, a nation of Ruſſia, which, at the ſeparation of the Mongolian monarchy, formed one ſtock with the Derbetans, but afterwards parted, under two diſcordant brothers of their princely family. It was this horde which, in the 17th and 18th centuries, reduced to their ſubjection a great part of the other Kalmuck races, particularly the Khoſchot, Derbet, and Kho-it; and waged bloody wars with the Mongoles, as well as with the Chineſe empire itſelf, but which ended in their total ſubjugation and diſperſion. Previouſly to this unhappy period, they, together with the Derbets, numbered upwards of 50,000 bows, or fighting men, and paſſed in modern times for the braveſt, richeſt, and moſt powerful horde. Their ſeat was formerly about the Balkhaſh lake, and its rivers Tſchuy and Ily; and their moſt flouriſhing period was between the years 1696 and 1746. The towns of the eaſtern Bucharia and the great Kirghiſe horde were, about this time, tributary to them. They conquered Budala, the capital of the Dalai-lama, and raiſed conteſts in Siberia, where they made tributary ſome nations belonging to Ruſſia. On the death of their khan Galdan Zeren, a diſſolution of the horde enſued, occaſioned by diſputes concerning the ſucceſſion; when the Torgots, the Khoſchots, and Derbets, ſeparated from it. Many of the Soongarians diſperſed themſelves in the interior parts of Aſia, and quite into the Uſbeck towns; ſome thouſands of them fled into Siberia; when the generality accommodated themſelves to the Chineſe ſovereignty: and from their own ſtatements it appears, that ſcarcely 20,000 families of them and of the Derbetan nation are now remaining. The number of the Soongares, who at that time (1758) took refuge in Ruſſia, amounted to about 20,000 perſons. They were united with the Volgaic Kalmucks, but for the moſt part returned with them, in the year 1770, again into the Soongarey. Tooke's View of the Ruſſ. Emp. vol. i.

SOONGEY PESANG *Bay*, a bay on the weſt coaſt of Sumatra. S. lat. 0° 57′. E. long. 99° 50′.

SOONKY, a town of Hindooſtan, in Bahar; 15 miles W.N.W. of Arrah.

SOONWALLA, a town of Hindooſtan, in Berar; 17 miles W. of Akoat.

SOONYGONG, a town of Hindooſtan, in Goondwana; 60 miles N. of Ramteak.

SOOP. See Soup.

SOOPA, in *Geography*, a town of Hindooſtan, in Dowlatabad; 27 miles E. of Poorunder.

SOOPOUR, a town of Napaul, on the borders of Bahar; 120 miles N. of Patna.—Alſo, a town of Bengal; 30 miles S.E. of Nagore. N. lat. 23° 38′. E. long. 87° 48′.—Alſo, a town of Bengal; 45 miles N.W. of Midnapour.—Alſo, a town of Hindooſtan; 5 miles N.W. of Benares.—Alſo, a town of Hindooſtan, in Oude; 46 miles N.N.E. of Gooracpour. N. lat. 27° 20′. E. long. 84° 13′.

SOOPSUNDY, a town of Hindooſtan, in the Carnatic; 10 miles S.S.E. of Tanjore.

SOOR, or Shoor, a name given to the river Indus, between Attock and Moultan.

Soor. See Tsor.

SOORANGUR, a town of Hindooſtan, in the Oriſſa country, near the river Mahanada; the burial-place of an Engliſhman of the name of Elliot, who died on his way from Calcutta to Nagpour in the year 1778. Mr. Haſtings cauſed a monument to be erected on the ſpot to his memory; 200 miles E. of Nagpour.

SOORAPATEE, a kingdom of the iſland of Java, on the ſouth coaſt, eaſt of Panaraga.

SOORAPETTA, a town of Hindooſtan, in Golconda; 33 miles S. of Combamet.

SOORATPOUR, a town of Hindooſtan, in Bahar; 10 miles N.N.E. of Arrah.

SOOREAH, a town of Hindooſtan, in the circar of Ruttunpour; 28 miles S.S.E. of Ruttunpour.

SOORJEW, a name given to the Dewah, in Thibet.

SOORMA, a river of Aſia, which riſes in Meckley, and runs into the Burrampooter, near Sunerampour, in Bengal.

SOOROOT, an iſland in the Eaſtern Indian ſea, about 25 miles in circumference. N. lat. 2° 45′. E. long. 108° 36′.

SOORORE, a circar of Bengal, bounded on the north, eaſt, and ſouth, by Coſſimpour and Dinagepour; and on the weſt by Rajemal; about ten miles long, and from five to eight broad. Bydell ſeems the chief town.

SOORWALL, a town of Hindooſtan, in Bundelcund; 35 miles W. of Allahabad.

SOORY, a town of Bengal; 7 miles E. of Nagore. N. lat. 23° 55′. E. long. 87° 38′.

SOOSELA, a town of Africa, in Kullo. N. lat. 12° 21′. W. long. 8° 40′.

SOOSNEER, a pretty large town of Hindooſtan, in Malwa, belonging to Sindiah. See OUGEIN.

SOOSOOHOONAM, or SOESOEHOONAM, often called *Soeſoehoonam Materam*, from the place of the reſidence of the emperor of Java, a kingdom or empire, being the fourth, of the iſland of Java. This empire formerly comprehended the greateſt part of the iſland; that of "Cheribon" formed a part of it, and it was then very powerful: but ſince the Dutch eſtabliſhed themſelves there, it has loſt much of its importance. Nevertheleſs it remained undivided till about the middle of the laſt century, when the emperor found himſelf ſo much embarraſſed, in conſequence of the rebellion of Manko Boeni, a prince of the blood, that he made a ceſſion of his territories to the Company; who, in return, granted him half of it as their vaſſal, and promiſed him their protection; engaging, at the ſame time, never to make any one emperor of Java, who was not a prince of the imperial family. The empire being thus divided, the other half was, in the ſame manner, given to Manko Boeni, as the Company's vaſſal, under the title of ſultan, with the like promiſe of protection, and the like engagement never to nominate any other than princes of his family, as ſucceſſors to his dignity. This other half conſtitutes the fifth empire of Java. The capital of Soeſoehoonam is Jolo.

SOOSWARGUR, a town of Hindooſtan, in Sumbulpour; 32 miles W. of Sumbulpour.

SOOT, an earthy volatile matter, ariſing from wood, coals, and other fuel, along with the ſmoke, by the action of fire; or rather, it is the ſmoke itſelf, fixed and detained on the ſides of the chimney.

Soot is a collection of ſubſtances formed by the matter in the flame of inflammable bodies, but which have eſcaped perfect combuſtion, from not having ſufficient contact with the vital air. Hence it is that the ſoot may be burned over again, and hence likewiſe it is that when the combuſtion is very rapid and effectual, there is no perceptible ſmoke, becauſe all the inflammable matter is then deſtroyed; as in the cylinder lamps, violent fires, &c. This matter is always of a black colour, more or leſs browniſh, which colour it acquires from an oil that is burnt, and half reduced to the ſtate of coal. Its different qualities and appearances are owing to the nature of the inflammable ſubſtances which produce it, and the different manner in which they are burnt.

Chimney ſoot is a compound of black carbonaceous matter with a conſiderable quantity of carbonated ammonia, and probably ſome other ammoniacal ſalts; and hence it gives a ſtrong pungent ſmell of this alkali, when rubbed with quicklime. The analyſis of ſoot exhibits an oil, which may be extracted by diſtillation; a reſin, which may be taken up by alcohol, and which ariſes either from the imperfect alteration of the reſin of the vegetable, or the combination of vital air with the volatile oil. It likewiſe affords an oil, which is often formed by the decompoſition of mucus; and it is this acid, of great utility in the arts, for which the academy of Stockholm have deſcribed a furnace proper for collecting it. Soot likewiſe affords volatile ſalts, ſuch as the carbonate of ammonia, and others. A ſlight portion of fibrous matter is likewiſe volatilized by the force of the fire, and it is again found in the ſoot.

Soot is moſtly formed from the combuſtion or burning of common or pit-coal, and in general contains ſome portion of matters derived from animal ſubſtances: it is conſequently powerful, when applied as a manure. In the trials of ſir Humphrey Davy, it was found to afford ammoniacal ſalts by diſtillation, and to yield a brown extractive matter, of a bitter taſte, by means of hot water. It is likewiſe ſaid to contain an empyreumatic oil, but that its great baſis is charcoal, in a ſtate in which it is capable of being rendered ſoluble by the action of oxygen and water.

The ſoot which is formed either from vegetables or from coal, is good both for corn and graſs, eſpecially on cold moiſt grounds, or lands apt to be over-run with moſs. Many have found their account in ſtrewing it early over their green wheat and barley crops; but Mr. Ellis ſays, neither of them ought to be ſooted after the 25th of April, becauſe the wheat, and generally the barley, have then done gathering and branching, and are upon the ſpindle. He likewiſe thinks it proper to be ſown over young turnips, juſt after they have appeared. But care ſhould always be taken not to ſtrew it too thick, leſt its hot nature ſhould hurt the plants. Mr. Worlidge ſeems to think wood-ſoot the beſt; but Mr. Mortimer prefers that which is made from ſea-coal, of which about 40 buſhels are commonly allowed to an acre; though ſome grounds will require more: to which he adds, that it produces a very fine ſweet graſs, and deſtroys worms and weeds; and that it ought not to be ſown upon wheat till Candlemas, becauſe the long cold rains and ſnows are apt to waſh it in too ſoon; nor is it ſafe to lay it on later, leſt a drought ſucceed, and burn it up. See MANURE and TOP-*Dreſſings*.

However, Mr. Donaldſon obſerves, that this uſeful manure can be obtained in conſiderable quantities only from great cities, or large manufacturing towns. The price in London, whence great quantities are carried to the adjacent diſtricts, is eight-pence the buſhel. The ordinary allowance is from 25 to 35 buſhels an acre. Soot is uſed in many parts of England, as Middleſex, Buckingham, Glouceſter, Wilts, Lancaſhire, Yorkſhire, &c. The mode of application is chiefly as top-dreſſings for young clover, ſainfoin, and old worn-out meadows. The beſt ſeaſon for laying it on is in February or March. It is carefully ſpread over the field with the hand, and always ſucceeds beſt, if rain immediately enſues. But Mr. Marſhall recommends its being ſown before rain, when a ſhower waſhes it in, and will be of obvious ſervice; but that if it lie on the ſurface long without rain, there will be no benefit derived from it. A rich ſoil wants no ſoot, but a ſoil much out of heart wants 40 or 50 buſhels. In his Rural Economy of Norfolk, he ſays, that the time of ſowing it over the land is conſidered as very material. If it be ſown early, and the froſt catch it, its ſtrength is thereby lowered; if late, and no rain falls to waſh it in, it is thought to be rather injurious than beneficial to the crop of wheat. And it is not, in any caſe, found of much, if any, ſervice to the ſucceeding crop of barley.

The method of ſowing it is extremely ſimple; and, in the only inſtance he ſaw, the ſowing of ſoot practiſed there was very complete. A favourable opportunity being embraced, when the wind blew gently, and in the direction, or nearly in the ſame direction, as the lands or ridges lie; the ſame waggon which brought it from Norwich, and which, until the opportunity offered, had ſtood ſafe under cover, was drawn in a furrow againſt the wind; while a man, ſtanding on the outſide of the waggon, ſpread the ſoot, with a ſhovel, ſeveral yards wide on either ſide of him; the height of his ſituation at once enabling him to ſpread it wide and even. As he reached the windward end of the lands, the team wheeled round under the hedges, and took a freſh width. The quantity ſet on was forty buſhels an acre in this caſe.

Mr. Young, however, remarks, that, in general, thirty buſhels are uſed for a complete dreſſing; that is, when dung or ſome other manure has not been previouſly applied to the ſame crop, which is very frequently the practice, and the quantity of top-dreſſing is then diminiſhed to about one-half of a complete dreſſing. Of ſoot, a complete dreſſing, as above, coſts from 30*s.* to 36*s.* *per* acre. Soot is found to anſwer beſt on wheat in April. It likewiſe ſucceeds on peaſe or clover in the ſame month, and has a good effect ſown *with* barley, in the beginning of April, and harrowed in. A ſlight dreſſing of ſoot is uſed at any time in the ſpring, when grubs or worms appear to injure the young corn. The worms frequently make great havoc, by drawing the blades of young corn after them into their holes: this ſoot prevents beſt: ſoot thinly diſtributed on newly ſown turnips, *juſt before* they come up, prevents the fly or grub from injuring them, provided no rain falls to waſh it into the ſoil. Soot anſwers beſt on light, dry, chalky ſoils, and in moderately wet ſeaſons. It does little good on ſtrong or wet land, or in very dry ſeaſons, unleſs ſown earlier than uſual. The London ſoot from coals is rarely bought unmixed with cork-duſt, coal-aſhes, or ſweepings of the ſtreets; yet, even in this adulterated ſtate, it is found to anſwer much better than real country ſoot from wood.

And it is remarked, in the Agricultural Survey of Hertfordſhire, that about Stevenage they ſpread from 20 to 40 buſhels an acre, bringing it from London: it coſts 8*d.*, and the carriage 3*d.*, in all 11*d.* *per* buſhel. And Mr. Clarke of Sandridgebury, ſpreads from 35 to 40 buſhels an acre on wheat. But about Beachwood they ſow from 30 to 40 buſhels on wheat, in February or March, bought at 1*s.* a buſhel at London, and bring 160 buſhels in a waggon with four horſes. Around Hitchin, 40 buſhels are ſown on wheat. And a good deal is uſed at Watford, at the rate of 40 buſhels an acre. Alſo, about Barkway they have a very high opinion of it; 50 buſhels an acre, brought 30 miles from London, are ſeen on wheat to an inch. And it is ſtated, in addition, that the practice is univerſal through this country; inſomuch, that the queſtion is, whether there is a pariſh in it in which ſome men are not in the habit of uſing this manure from London.

On cabbage crops that have been ſown, it has been found that if, as ſoon as the plants appear diſtinctly above the ground, a ſurge of ſoot be drilled upon them, to the amount of from 10 to 12 buſhels the acre, it affords much ſecurity againſt the fly. And it has been ſuggeſted that this buſineſs may be cheaply and conveniently executed by a hopper and round of cups, ſimilar to Cook's, but larger, fixed to a frame ſimilar to that of the Northumberland drill. When employed for preventing the fly in drilled turnips, it ſhould be ſprinkled along the rows, from a ſcuttle, by the hand, or ſome ſuch mean, in the proportion of about twenty buſhels the acre.

But in reſpect to the application of this ſort of ſubſtance to land, it is remarked by Mr. Kiddle, in the fourth volume of Communications to the Board of Agriculture, that all manures that are laid on the ſurface of land cannot be laid on too early in the ſeaſon. Soot, for inſtance, is always recommended to be ſown on wheats or clovers, and graſs-lands, in the month of February, from a notion, that if ſown ſooner, they would exhauſt themſelves too ſoon. This, he thinks, abſurd reaſoning. No manure can be of any ſervice to the crop, which it is meant to advantage, until it reaches the roots: and what contributes more to ſave it than the winter rains, and the diſſolving of the ſnow? He has, in conſequence, always ſown the ſoot for wheat and clover, when he has been able to procure it, in the month of November or December, and always with ſatisfaction to himſelf. He laſt year ſowed with ſoot an incloſure of wheat of eight acres, part of which was ſown in the beginning of December, before the froſt ſet in, and a heavy rain ſucceeded the ſowing; on the remaining parts, owing to his not being able to procure more ſoot at that time, the ſowing was poſtponed until after the froſt was gone, in the month of February. The quantity ſown on an acre, in both inſtances, was equal; but the ſuperiority of the crop of wheat, where it was ſown early, might be diſcerned by the eye. He had the curioſity to have it thraſhed ſeparately, and found its increaſe beyond the other conſiderable. If he could procure ſoot at the time of ſowing wheat, he ſhould be under no apprehenſion of its anſwering then, if the land was worked for the wheat. Some years ſince, having bought a ſmall quantity of ſoot immediately after harveſt, he had the deſire to try its effects on the crop at that early ſeaſon, and having a pea-ſtubble which had been ploughed twice, and was deſigned for wheat, after ſowing as much of the land as he had ſoot for with wheat, he then had the ſoot ſown, and ploughed both in together. He owns he was anxious to ſee the ſucceſs of his experiment, as it was a novel one, as were his neighbours alſo who had ſeen it done. The remainder of the land was ſown with ſoot, as he was able to procure it. The wheat, where the ſoot was ſoon with it, kept the lead during the firſt months: this he did not wonder at, but expected it from its forcing quality; but he was very much pleaſed to ſee it continue to do ſo during the remainder of the ſeaſon, and at harveſt the ſuperiority in favour of it was eaſily to be ſeen.

Soot, in ſome diſtricts, as where the ſoil is rather inclining to be ſtrong and heavy, is far from being found a durable manure, though it commonly produces very ſtrong crops for the firſt year. And it is in other places more commonly applied over the graſs-lands than the tillage crops, being ſuppoſed more uſeful and proper in ſuch a manner of application. But it is not improbable but that it is a ſort of manure that may in general be the beſt fitted to be employed in its dry ſtate by being thrown into the ground at the ſame time with the ſeed, ſomewhat in the manner of powdered rape-cake, having the advantage of requiring no ſort of preparation when uſed in this way.

Some ſuppoſe that 20 buſhels of ſoot to the acre are nearly equal to 50 of the aſhes of either coals, wood, or peat. And the writer of the Middleſex corrected Agricultural Report remarks, that the ſmoke, conſiſting of the lighteſt particles of ſoot and coal, raiſed by the force of the aſcending current of rarefied air ariſing from 300,000 fires in the metropolis and its vicinity, is daily depoſited on the ſurrounding country; where the next rain waſhes it into the ſoil, and it promotes vegetation and the fertility of the land to a conſiderable degree.

The dyers make a conſiderable uſe of ſoot, for a kind of dun-colour; which, it is true, has no agreeable ſmell; but, in return, it has the property of ſaving clothes, and other ſtuffs, from moths.

Carbonated ammonia is extracted from it in the large way in ſeveral manufactories of this ſalt.

Soot *of Frankincenſe*, is the ſmalleſt and fineſt part of the incenſe called olibanum, or male incenſe; burnt after the manner of roſin, to make lamp-black.

Soot, *Wood*, was formerly regarded as a good medicine in many caſes, but the principles upon which it acted as ſuch were never well underſtood, till Boerhaave gave a regular analyſis of it. The directions he gives for the proceſs are theſe.

Chooſe the blackeſt and dryeſt wood-ſoot from the chimney of an oven, where nothing is baked but bread, and nothing burnt but vegetables; gather this in a dry day, and fill with it a glaſs retort almoſt up to the neck; clean the neck of the retort, and luting on a receiver, give a fire of 150°, and keep it up equably, a large quantity of tranſparent water will come over with conſiderable violence. When no more water will come over, cleanſe the receiver, and raiſing the fire to a little above 200°, there will then come over a whitiſh fat liquor; this alſo comes over with great violence, and the fire muſt be gradually increaſed, till no more of this will come. Change the receiver, and raiſe the fire to a yet greater degree, and a yellow, copious, volatile ſalt will come over, and ſtick all over the ſides of the new receiver. When no more of this ſalt will ariſe, increaſe the fire to the utmoſt that ſand can give, and with a heat of ſuppreſſion there will ariſe a black thick oil; when this is all come over, and the veſſels cooled, there will be found in the neck of the retort a ſalt, which could be raiſed no higher, even by that violent fire; and in the bottom of the retort there remains a black feculent matter, the upper ſurface of which is covered with a white ſaline cruſt, which, both in figure, colour, and the ſtructure of its ſtriæ, reſembles the common ſal ammoniac. If the milky liquor be rectified, it affords a very penetrating volatile ſpirit, and ſome ſharp volatile ſalt.

Here we are taught what the agitation of an open fire can move, change, expel, and drive through the air by burning; firſt in the form of ſmoke, then of flame, and laſtly of exhalation, and how high it is able to carry them; for a chimney is a kind of ſtill-head, converging in an open top, and ſoot is often carried up thirty or forty feet, or more, to the top of theſe, and after this a black ſmoke is diſcharged out of the orifice, which diſperſes in the air, and finally ſeems to vaniſh.

From his accurate analyſis of wood-ſoot, we may learn, ſays Boerhaave, that ſoot, which contains ſo many active principles, muſt be qualified for a powerful medicine. Pills of dry ſoot are found very beneficial in all cold diſtempers; the volatile ſalt of ſoot poſſeſſes the virtues of the volatile ſalts of animals. The ſalt which riſes laſt is recommended greatly by Hartman for giving relief in cancers; and this is very probable, ſince ſal ammoniac of the common kind, properly applied, is known to be of great uſe in caſes of running cancers. Soots of different fuels are not all to be ſuppoſed to poſſeſs the ſame virtues; that of pit-coal is found to be a ſubſtance of a very different kind from that of wood; and that of the common turf or peat, and of the oak-wood, have alſo been found, on experiment, to be very different.

Boerhaave very juſtly obſerves, that the ſoot from kitchen-chimneys, where the ſmoke muſt have been impregnated with the effluvia of the victuals, muſt be very different from pure wood-ſoot. Boerhaave's Chemiſtry.

Wood-ſoot was formerly directed in hyſteric caſes, and in different nervous diſorders, as an antiſpaſmodic and corroborant. It was uſed chiefly in the form of a ſpirituous tincture, in conjunction, commonly, with aſſa-fœtida, or other materials of ſimilar intention: the officinal tincture was drawn from two ounces of ſoot, and one of aſſa-fœtida, with a quart of proof ſpirit.

The virtues of the ſoot are extracted almoſt equally by proof ſpirit, rectified ſpirit, and water, each of which, if the ſoot is of a good kind, diſſolves about one-fourth of it.

The extracts, obtained by inſpiſſating the filtered ſolutions, are very bitter, and the ſpirituous extract retains moſt perfectly the peculiar flavour of the ſoot. Lewis.

Dioſcorides ſhews how to make a ſoot of butter, which was thought to have ſeveral uſes in medicine. The ſoot found in furnaces of glaſs-houſes is uſed by painters.

SOOTA, in *Geography*, a town of Japan, on the N. coaſt of the iſland of Sado.

SOOTEEAH, a town of Hindooſtan, in Bahar; 15 miles N.N.E. of Chuprah.

SOOTEREE, a town of Bengal; 12 miles S.E. of Ramgur.

SOOTICH, a town of Bengal; 15 miles N.N.E. of Kiſhenagur.

SOOTY, a town of Bengal; 30 miles N.E. of Calcutta.—Alſo, a town of Bengal; 27 miles N. of Moorſhedabad. N. lat. 24° 25′. E. long. 88° 11′.

SOPE. See Soap.

SOPEDIERO, in *Geography*, a town of Mexico, in New Biſcay; 140 miles S.S.W. of Parral.

SOPETRAN, a town of Spain, in New Caſtile; 10 miles N. of Guadalaxara.

SOPHA, in *Ancient Geography*, a town of Paleſtine, in the tribe of Zebulon, according to Epiphanius.

SOPHANITÆ, a people of Arabia Felix, placed by Ptolemy in the ſouthern part of that country.

SOPHAR, a town of Judea, in the tribe of Gad.

SOPHECLA, in *Geography*, a ſmall iſland in the gulf of Engia; 5 miles N.W. of Engia.

SOPHENA, Zoph, in *Ancient Geography*, a country of Aſia, in the Greater Armenia, N. of Meſopotamia and Comagene, between the mountains Maſius and Antitaurus, according to Strabo.

SOPHERA, in *Botany*. See Cassia and Sophora.

SOPHI, or Sofi, a title of quality, given to the emperor of Perſia; importing as much as wiſe, ſage, or philoſopher.

The title is by ſome ſaid to have taken its riſe from a young ſhepherd thus named, who attained to the crown of Perſia in 1370; others derive it from the *ſophoi*, or ſages, anciently called *magi*. Voſſius gives a different account of the word: *ſophi*, in Arabic, he obſerves, ſignifies wool; and he adds, that it was applied by the Turks out of deriſion to the kings of Perſia, ever ſince Iſhmael's time; becauſe, according to their ſcheme of religion, he is to wear no other covering on his head, but an ordinary, red, woollen ſtuff; whence the Perſians are alſo called *hazelbaſchs*, q. d. *red-heads*. But Bochart aſſures us, that ſophi, in the original Perſian language, ſignifies one that is pure in his religion, and who prefers the ſervice of God in all things: and derives it from an order of religious called by the ſame name.

The ſophis pride themſelves, and with ſome reaſon, on their illuſtrious extraction; the race being ſecond to none in the Eaſt. They are deſcended in a right line from Houſſein, ſecond ſon of Ali, Mahomet's couſin, and Fathima, Mahomet's daughter.

There is no prince in the world whoſe authority is more abſolute than that of the ſophi of Perſia; his power is not even limited by any laws he himſelf can make; but he ſuſpends, changes, and annuls them at pleaſure. See Sophis.

SOPHIA, or Sofia, in *Geography*, a city of European Turkey, in Bulgaria, built by Juſtinian on the ruins of the ancient Sardica. This is the capital of Bulgaria, and a ſangiacat; the ſee of a Greek archbiſhop, and of a Roman biſhop. It is commercial, populous, and well-built, but without walls; and the ſtreets are narrow, uneven, and dirty: 280 miles W.N.W. of Conſtantinople. N. lat. 42° 56′. E. long. 23° 14′.

Sophia *Chirurgorum*, in *Botany*, a name ſometimes given to a ſpecies of water-creſſes.

SOPHIAI, in *Geography*, a town of Ruſſia, in the government of Peterſburg; 16 miles S.S.E. of Peterſburg. N. lat. 59° 40′. E. long. 13° 14′.

SOPHIANA, a town of Perſia, in the government of Adirbeitzan, or Azerbijan; 24 miles N.W. of Tauris.

SOPHIENBERG, a town of Denmark, in the iſland of Zealand, near the coaſt of the Sound, with a royal palace; 13 miles N. of Copenhagen.

SOPHIENBURG, a town of Germany, in the principality of Culmbach; 5 miles S. of Bayreuth.

SOPHIENLUST, a town of Germany, in the county of Henneberg; 3 miles S. of Meinungen.

SOPHIS, or Sofees, denote a kind of order of religious among the Mahometans in Perſia, anſwering to what are otherwiſe called *derviſes;* and among the Arabs and Indians, *faquirs*.

Some will have them called ſophis, from a kind of coarſe camblet which they wear, called *ſouf*, from the city Souf, in Syria, where it is principally manufactured.

The more eminent of theſe ſophis are complimented with the title *ſcheik*, that is, *reverend;* much as in Romiſh countries the religious are called *reverend fathers*.

Sheick Sophi, who laid the firſt foundation of the grandeur of the royal houſe of Perſia, was the founder, or rather the reſtorer, of this order: Iſhmael, who conquered Perſia, was himſelf a ſophi, and greatly valued himſelf on his being ſo. He choſe all the guards of his perſon from among the religious of this order; and would have all the great lords of his court ſophis.

The king of Perſia is ſtill guard-maſter of the order; and the lords continue to enter into it, though it be now fallen under ſome contempt.

The vulgar ſophis are now chiefly employed as uſhers and attendants of the court; and ſome even as executioners of juſtice; the emperor laſt reigning would not allow them, according to cuſtom, to gird the ſword on him.

This neglect into which the ſophis are ſunk, has occaſioned the late emperor to diſuſe the title of *ſophi*, or *ſofi:* however, M. de la Croix is miſtaken, when he ſays, that they never bore it.

Sophis, *Sofees*, or *Suſi's*, the denomination of a ſect of modern philoſophers among the Perſians, whoſe name is derived either from the Greek word for a ſage, or from the woollen mantle which they uſed to wear in ſome provinces of Perſia. They ſeem, ſays ſir William Jones (Works, vol. iii. p. 130. 8vo. ed.) to have adopted that metaphyſical theology, which has been profeſſed immemorially by a numerous ſect of Perſians and Hindoos, which was carried into Greece, and which prevails, even at this time, among the learned Muſſulmans, who ſometimes avow it without reſerve. Their fundamental tenets are, that nothing exiſts abſolutely but God: that the human ſoul is an emanation from his eſſence; and, though ſeparated for a time from its heavenly ſource, will be finally reunited with it: that the higheſt poſſible happineſs will ariſe from its reunion; and that the chief good of mankind, in this tranſitory world, conſiſts in as perfect an *union* with the eternal Spirit, as the incumbrances of a mortal frame will allow: that, for this purpoſe, they ſhould break all *connection* with extrinſic objects, and paſs through life without *attachments*, as a ſwimmer in the ocean ſtrikes freely without the impediment of clothes: that they ſhould be ſtraight and free as the cypreſs, whoſe fruit is hardly perceptible; and not ſink under a load, like fruit-trees *attached* to a trellis: that, if mere earthly charms have power to influence the ſoul, the *idea* of celeſtial beauty muſt overwhelm it in extatic delight: that, for want of apt words to expreſs the divine perfections with the ardour of devotion, we muſt borrow ſuch expreſſions as approach the neareſt to our ideas, and ſpeak of *beauty* and *love* in a tranſcendent and myſtical ſenſe: that, like a *reed* torn from its native bank, like *wax* ſeparated from its delicious honey, the ſoul of man bewails its diſunion with *melancholy muſic*, and ſheds burning tears like the lighted taper, waiting paſſionately for the moment of its extinction, as a diſengagement from earthly trammels, and the means of returning to its only Beloved.

Such, in part, is the wild and enthuſiaſtic religion of the modern Perſian poets, eſpecially of the ſweet Hafiz, and the great Maulavi. Such is the ſyſtem of the Vedanti philoſophers, and beſt lyric poets of India; and, as it was a ſyſtem of the higheſt antiquity in both nations, it may be added to many other proofs of an immemorial affinity between them. The philoſophy of the Sofees ſeems alſo, in early times, to have prevailed amongſt the Jews, in Europe among the *Theoſophiſts* (ſee that article), as well as among the diſciples of the Vedanti ſchool in India. Sir William Jones has expreſſed with great preciſion the tenets of the Indian ſchool, nor do they differ from the doctrines maintained by the Sofees of the preſent day. The fundamental tenet of the Vedanti ſchool, ſays ſir W. Jones (Works, vol. iii. p. 239. 8vo. ed.) to which, in a more modern age, the incomparable Sancara was a firm and illuſtrious adherent, conſiſted not in denying the exiſtence of matter; that is, of ſolidity, impenetrability, and extended figure; but in correcting the popular notion of it, and in contending that it has no eſſence independent of mental perception; that exiſtence and perceptibility are convertible terms; that external appearances and ſenſations are illuſory, and would vaniſh into nothing, if the divine energy, which alone ſuſtains them, were ſuſpended but for a moment, an opinion which Epicharmus and Plato ſeem to have adopted, and which has been maintained in the laſt century, and in our own country, with great elegance and acuteneſs by Berkeley and others. The Sofees conſider themſelves, as we have above ſtated, immerſed in depravity by an union with matter, and in the figurative ſtyle of their poets, lament the ſeparation from their beloved, and ſolicit, with impatient ardour, a releaſe from a material and earthly bondage.

SOPHISM, Σοφισμα, in *Logic*, a captious and fallacious reaſoning; or an argument, which, with ſome ſubtlety, carries much appearance of truth, but little ſolidity. See Fallacy.

A ſophiſm is, properly, an argument falſe at bottom, and only invented to amuſe and embarraſs the perſon to whom it is uſed.

Logicians enumerate the following kinds of ſophiſm, *viz. ignoratio elenchi*, or a miſtake of the queſtion, *i. e.* when ſomething elſe is proved, which has neither any neceſſary connection nor inconſiſtency with the thing inquired, and conſequently gives no determination to the inquiry, though at firſt ſight it may ſeem to determine the queſtion; *petitio principii;* a circle; *non cauſa pro cauſa*, or the aſſignation of a falſe cauſe; *fallacia accidentis*, which pronounces concerning the nature and eſſential properties of any ſubject, according to ſomething which is merely accidental to it. *A dicto ſecundum quid ad dictum ſimpliciter*, arguing from that which is true in particular circumſtances, to prove the ſame thing true abſolutely, ſimply, and abſtracted from all circumſtances, and *vice verſâ:* the ſophiſms of compoſition and diviſion, when we infer any thing concerning ideas in a compounded ſenſe, which is only true in a divided ſenſe, and *vice verſâ:* and the ſophiſms ariſing from an abuſe of the ambiguity of words: to which may be added an imperfect enumeration, or falſe induction, when from a few experiments and obſervations, men infer general theorems and univerſal propoſitions. Watts's Logic, p. iii. c. 3. ſect. 1.

Theſe ſophiſtical modes of reaſoning, or logical quibbles, called by Ariſtotle Eriſtic ſyllogiſms, were introduced into the Megaric ſchool, founded by Euclid of Megara, (ſee his article,) by Eubulides of Miletus, who in that ſchool ſucceeded Euclid; but as they furniſhed merely examples of egregious trifling, they deſerve no farther notice. The Stoics alſo amuſed themſelves with quibbles and fallacies of the ſame kind with thoſe of the Megaric ſchool, of which the following example will be ſufficient. Protagoras the ſophiſt (ſee PROTAGORAS) agreed to inſtruct a young man in eloquence for a large ſum, one half of which was to be paid in hand, the other half upon his firſt ſucceſsful pleading in the courts. Neglecting to plead for a long time after Protagoras had completely inſtructed him in the art of rhetoric, the ſophiſt ſued him for the remaining moiety of his ſtipend. Each pleaded his own cauſe. Protagoras urged, that which way ſoever the cauſe was determined, the young man muſt complete the payment: for if the cauſe was determined *againſt* the defendant, the payment would be granted him by judgment; if *for* him, the payment would be due according to agreement. The young man, on the contrary, pleaded, that if the cauſe was determined *in his favour*, he ſhould be excuſed from the payment by the deciſion of the court; if *againſt* him, Protagoras, by his own agreement, could have no demand upon him. The ſubtlety of theſe pleas perplexed the judges; and, without coming to any determination, they diſmiſſed the court.

SOPHISMS, or *Sophiſtical Arguments*, among *Logicians*, are more particularly ſuch as are not in form, or are founded on equivocals.

As, *You have every thing you have not loſt; but you have not* loſt *horns, therefore you have horns.*

SOPHIST, Σοφιϛης, formed from σοφος, *wiſe*, or rather from σοφιϛης, *impoſtor*, *deceiver*, a perſon who frames ſophiſms; that is, uſes ſubtle arguments, with deſign to deceive thoſe whom he would perſuade or convince.

The term ſophiſt, which is now reproachful, was anciently honourable, and carried a very innocent idea. St. Auguſtine obſerves, it ſignifies a rhetor, or profeſſor of eloquence: ſuch as were Lucian, Athenæus, Libanius, &c. Suidas, and after him Olar. Celſius, in an expreſs diſſertation on the Greek ſophiſts, tells us, that the appellation was applied indifferently to all who excelled in any art or ſcience; whether divines, lawyers, phyſicians, poets, orators, or muſicians.

However, as rhetoricians often employed their art rather to vindicate what was falſe and unjuſt, than to ſupport truth and virtue, their conduct brought a diſcredit both upon themſelves and their profeſſion; and, therefore, the name *ſophiſt*, ſometimes confounded with that of *ſophiſter*, has been uſed in an ill ſenſe, to ſignify a ſpecious but falſe reaſoner, one ſkilled rather in the arts of cavilling than qualified to ſpeak well and accurately upon any ſubject.

Solon is the firſt who appears to have ever borne the appellation of ſophiſt, which is given him by Iſocrates; afterwards, it was ſcarcely ever given, except to philoſophers and declaimers.

In the time of Socrates, there was in Athens a large body of profeſſional preceptors of eloquence, diſtinguiſhed by the appellation of ſophiſts. By the mere pomp of words, theſe men made a magnificent diſplay of wiſdom, upon a ſlight foundation of real knowledge; and they taught an artificial ſtructure of language, and a falſe method of reaſoning; by means of which they were able, in argument, to make the worſe appear the better cauſe. Whilſt they arrogated to themſelves the merit of every kind of learning, they publicly practiſed the art of diſputing with plauſibility on either ſide of any queſtion, and profeſſed to teach this art to the Athenian youth. By theſe impoſing pretenſions, they collected, in their ſchools, a numerous train of young men, who followed them in hope of acquiring thoſe talents, which would give them influence and authority in popular aſſemblies. In ſuch high repute were theſe ſophiſts, that they were literally ſupported, not only by contributions from their pupils, but by a regular ſalary from the ſtate; and were in many inſtances diſtinguiſhed by public honours, and employed in offices of magiſtracy. Of their enmity to Socrates, we have given an account under his biographical article.

The title *ſophiſta* was in great credit among the Latins in the twelfth century, and in the time of St. Bernard; but it began to loſe ground in Greece as early as Plato's time; on account of Protagoras and Gorgias, who made a ſordid traffic of it, by ſelling eloquence for money. Hence Seneca calls the ſophiſts quacks, or empirics.

Cicero ſays, that the title *ſophiſti* was in his time given to ſuch as profeſſed philoſophy with too much oſtentation, in order to make a trade of it, by running from town to town, to retail their deceitful ſcience. A ſophiſt, therefore, was then, as now, a rhetor, or logician, who makes it his buſineſs to enſnare and perplex people, by frivolous diſtinctions, vain reaſonings, and captious diſcourſes.

Nothing has conduced more to the increaſing of the number of ſophiſts than the contentious ſchool-philoſophy: people are there taught to puzzle and obſcure the truth, by barbarous unintelligible terms; as, antipredicaments, great and little logicals, quiddities, &c.

The title ſophiſt was given to Rabanus Maurus, by way of eminence. John Hinton, a modern Engliſh ſcholaſtic writer, endeavoured alſo to procure the ſplendid title of ſophiſt.

SOPHISTICATION, in *Chemiſtry*, *Alchemy*, &c. a term particularly applied to the counterfeit works of fraudulent alchemiſts, who uſe indirect means of whitening copper, gilding ſilver, and giving other ſuperficial tinctures to metals; as alſo of making augmentations, by divers mixtures, and other illegal operations, to delude thoſe at whoſe expence they are employed.

Hence the term is alſo applied to merchandizes, and other goods adulterated, mixed, or altered, by the deceit of the ſeller.

SOPHOCLES, in *Biography*, a celebrated tragic poet, was born at Athens about the year 497 B.C. He received an education in every way ſuitable to his rank in life; and it appears that he was but a youth, when the monuments of the victory over Xerxes were fixed up at Salamis, and then he went at the head of a chorus of noble birth, whoſe ſong of triumph he led by the ſtrains of his lyre. He firſt applied himſelf to lyric poetry; but the fame acquired by Æſchylus, the author, or at leaſt the great reformer, of Grecian tragedy, induced him to try his powers in that ſpecies of compoſition; and in his 28th year he ventured to contend with that veteran for the theatrical prize. He obtained the victory, which was followed by the retreat of his rival, who left him the undiſputed maſter of the tragic ſtage. The improvements introduced by Sophocles were ſo great, that he has generally and juſtly been regarded as the father of the regular tragedy. "He brought," ſays the critic, "a third interlocutor to the two who before alone appeared on the ſcene at once; he intereſted the chorus in the ſubject of the piece; he reduced the turgid and unnatural diction of Æſchylus to the proper ſtandard of heroic dignity; and invented that artful conſtruction of fable and developement of incidents, which contribute ſo much to the intereſt of a dramatic performance." In theſe points he was ſuperior to his younger competitor Euripides; and upon the whole, he appears to have ſtood at the head of his claſs, in the judgment both of Greek and Roman critics. Cicero terms him a *divine poet;* and he is highly commended by Dionyſius of Halicarnaſſus, for preſerving the dignity of his characters, and dwelling rather on the more noble and generous affections, than on the mean and debaſing paſſions. Theſe praiſes ſhew that his works were regarded as the moſt perfect example of tragedy, in the higheſt ſenſe of the word. Sophocles was a ſtateſman, as well as a tragedian, and entruſted with very important civil and military employments. He retained his faculties to the laſt, and continued to write tragedies to an advanced age; and when his unnatural ſons, on account of ſome neglect in his domeſtic affairs, applied to the magiſtrates to put him under their guardianſhip, as having outlived his underſtanding, he appeared in court, an advocate in his own cauſe, and reciting his Œdipus at Colonus, which he had juſt finiſhed, appealed to the judges and auditors, if that were the work of the dotard deſcribed by his own children. The ſentence was pronounced unanimouſly in his favour, and he was carried home with every mark of triumph. The benignity of his character acquired him a number of friends, his attachment to whom, and his moderate wiſhes, cauſed him to decline the invitations of the kings who were deſirous of drawing him to their courts. He paid every token of reſpect to the memory of his rival Euripides, thus demonſtrating that he was incapable of the meanneſs of jealouſy. He lived to the great age of 90, and is ſaid even at that age to have died with joy, on obtaining the prize for his laſt tragedy. Above a hundred pieces have been attributed to him by ſome ancient writers, of which, however, only ſeven have reached our times. Of theſe, both ſeparately and collectively, many editions have been made. Among the moſt eſteemed are Johnſon's, 3 vols. 8vo. Oxon. et Lond.; Capperonier's, Par. 4to.; Brunck's, 2 vols. royal 8vo. 1786; and Muſgrave's, Oxon. 2 vols. 8vo.

SOPHONE, in *Ancient Geography*, a country of Aſia, ſituated in the place where the Tigris re-appears, after having been under ground for the ſpace of 25 miles, according to Juſtin.

SOPHORA, in *Botany*, a name of moſt whimſical origin. *Sophera* is, according to Proſper Alpinus, the Egyptian denomination of a ſpecies of *Caſſia*, the Linnæan *C. Sophera*, nearly related to the genus before us. Linnæus, in his *Hortus Cliffortianus*, 156, ſpelling it *Sophora*, calls it a *genus ſophorum*, or of wiſe men; as teaching that ſeparate ſtamens, in the papilionaceous family, if ever the limits of that family can be determined, afford ſo deciſive a mark of diſcrimination, as almoſt to exclude the plants furniſhed with ſuch, from the ſame natural claſs, or order, with thoſe whoſe filaments are combined. The ſoundneſs of the doctrine may make us tolerate the conceit.—Linn. Gen. 204. Schreb. 275. Willd. Sp. Pl. v. 2. 499. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 2. Juſſ. 351. Lamarck Illuſtr. t. 325. Gærtn. t. 149, tomentoſa. (Edwardſia; Saliſ. in Tr. of Linn. Soc. v. 9. 298. Ait. Hort. Kew. v. 3. 1.)—Claſs and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, ſhort, oblique; gibbous on the upper ſide; its tube turbinate, angular; limb bell-ſhaped, abrupt, with five teeth. *Cor.* papilionaceous, of five petals. Standard oblong, ſtraight, dilated upwards, deflexed at the ſides, various in length. Wings two, as long as the ſtandard, or longer, with a lobe at the baſe. Keel of two petals, ſimilar to the wings and about the ſame length, their lower edges cloſe together, boat-like. *Stam.* Filaments ten, inſerted into the tube of the calyx, diſtinct, parallel, rigid, awl-ſhaped, about the length of the corolla, and lodged in its keel, deciduous; anthers ſmall, oval, incumbent. *Piſt.* Germen ſuperior, oblong, ſlender, nearly cylindrical; ſtyle the ſize and ſhape of the ſtamens; ſtigma ſimple, obtuſe. *Peric.* Legume very long and ſlender, of one cell, and two imperfect valves, ſwelling at each ſeed, ſo as to become beaded; often angular or winged. *Seeds* numerous, roundiſh, large, poliſhed.

Eſſ. Ch. Calyx bell-ſhaped, oblique, five-toothed; turbinate at the baſe. Corolla papilionaceous. Legume beaded, ſcarcely burſting, with many ſeeds.

We have under Edwardsia (ſee that article) expreſſed an opinion unfavourable to the permanency of that genus of Mr. Saliſbury's, though we have many reaſons for wiſhing we could admit it; nor does our deciſion at all interfere with the propriety of the name. Our reaſons will appear preſently. The genus of *Sophora* is, nevertheleſs, commodiouſly diviſible into two ſections, by the ſituation of the infloreſcence, but this can make no generic diſtinction, unleſs it were ſupported by ſome character in the fructification, ſuch as the learned editors of the *Hortus Kewenſis* thought they had found in the legume; but it is overſet by a new ſpecies before us; ſee n. 5.

Section 1. *Cluſters terminal, elongated.*

1. S. *tomentoſa.* Downy Sophora. Linn. Sp. Pl. 533. Willd. n. 5. Ait. n. 1. (S. occidentalis; Linn. Sp. Pl. 533. Willd. n. 6. S. arboreſcens, &c.; Trew's Ehret, 27. t. 59. Colutea zeylanica argentea tota; Herm. Lugd.-Bat. 169. t. 171. Galega? n. 1; Browne Jam. 289. t. 31. f. 1.)—Stem arboreous. Leaflets numerous, roundiſh-elliptical, very obtuſe, downy as well as the calyx.—Native of the Eaſt and Weſt Indies. Long cultivated in our ſtoves, but it has ſeldom flowered. The *branches*, *ſtalks*, *foliage*, and *infloreſcence*, are more or leſs clothed with ſhort, denſe, hoary pubeſcence. *Leaves* a ſpan long, of ſix or ſeven pair, with an odd one, of ſtalked, elliptical, coriaceous *leaflets*, all nearly equal and uniform, above an inch long; ſometimes their upper ſurface is ſmooth, and the whole of the plant much leſs downy than uſual. *Stipulas* none. *Cluſters* terminal, ſolitary, ſtalked, ſimple, generally a foot long, compoſed of very numerous, large, elegant, pale-yellow *flowers*. *Legume* three or four inches in length, beaded, two-edged, ſlightly downy, often interrupted here and there by a failure in the impregnation of ſome of the *ſeeds*, which, when perfect, are the ſize of a large pea, globular, brown, diſcharged finally by the decay, and partial ſplitting of the valves.

2. S. *heptaphylla.* Seven-leaved Sophora. Linn. Sp. Pl. 533. Willd. n. 8. (Anticholerica; Rumph. Amboin. v. 4. 60. t. 22.)—Stem ſhrubby. Leaflets about ſeven, elliptical, acute; downy beneath.—Native of the Eaſt

Indies, on ſandy or rocky ſea-coaſts. Rumphius deſcribes it as about the ſize of a Privet-buſh, but with a thicker trunk. He ſays there are ſeven, eight, or nine pair of *leaflets*, beſides an odd one; dark green above; downy and grey beneath; hardly two inches long, about one broad. Linnæus deſcribes ſeven ſmooth *leaflets* in all. The *flowers* are yellowiſh. *Legumes* beaded. Having ſeen no ſpecimen, we forbear all further deſcription; only excluding, without heſitation, the *Fruticulus ſinenſis, ſenæ ſylveſtris folio*, &c. Pluk. Amalth. append. t. 451. f. 10. (See the next ſpecies.) The *root* and *ſeeds* of the plant of Rumphius are celebrated by him as ineſtimable remedies for dangerous bilious colics.

3. S. *japonica*. Japaneſe Sophora. Linn. Mant. 68. Willd. n. 7. Ait. n. 2. Thunb. Jap. 178. Andr. Repoſ. t. 585. Jacq. Hort. Schoenbr. v. 3. 55. t. 353.—Stem arboreous. Leaflets ovato-lanceolate, acute, ſmooth. Cluſters compound, panicled.—Native of Japan and China. Introduced by the celebrated cultivator Mr. James Gordon, in 1753. It has been nearly as long cultivated about Paris, where it was called *l'arbre inconnu des Chinois*. This is a tall and handſome hardy deciduous *tree*, with elegant, ſmooth, pinnate *leaves*, whoſe *leaflets* are about an inch and a half long, and half an inch broad, acutely pointed. *Flowers* ſmaller than thoſe of Laburnum, of a pale greeniſh-yellow, almoſt white, compoſing numerous, branched, ſpreading *cluſters*, collected into large, terminal, upright *panicles*. *Legumes* pendulous, two or three inches long, turgid, ſmooth. By Jacquin's figure the withered *ſtamens* ſeem permanent. Perhaps Plukenet's Amalth. t. 451. f. 10, cited with doubt by Linnæus for *S. heptaphylla*, may belong to this.

4. S. *alopecuroides*. Fox-tail Sophora. Linn. Sp. Pl. 533. Willd. n. 4. Ait. n. 3. (Glycirrhiza ſiliquis nodoſis, quaſi articulatis; Buxb. Cent. 3. 25. t. 46. Ervum orientale alopecuroides perenne, fructu longiſſimo; Dill. Elth. 136. t. 112. f. 136.)—Stem herbaceous. Leaflets elliptic-oblong, obtuſe; ſomewhat ſilky beneath, when full grown.—Native of the Levant, hardy in our gardens, where it was cultivated in the days of Miller and Sherard, flowering in July and Auguſt. The *root* is perennial, creeping extenſively. *Stems* annual, herbaceous, ſimple, leafy, about two feet high. *Leaflets* numerous, about an inch long, green, ſparingly pubeſcent. *Cluſters* ſimple, ſolitary at the top of each ſtem, without much of an elongated ſtalk, compoſed of numerous, pale, greeniſh-white, ſweet-ſcented *flowers*, larger than thoſe of the common *Galega officinalis*. *Calyx* nearly ſmooth. *Legume* ſlender, ſomewhat ſilky. Dillenius noticed the ten diſtinct *ſtamens;* and he aſſerts that to make the plant flower freely, the roots muſt be confined in a pot.

5. S. *flaveſcens*. Siberian Sophora. Ait. ed. 1. v. 2. 43. ed. 2. n. 4. Willd. n. 3.—"Stem herbaceous. Leaflets ovate-oblong, nearly ſmooth."—Native of Siberia; introduced here in 1785, by Mr. John Bell. A hardy perennial, flowering from May to July. We have ſeen no ſpecimen. Willdenow ſays it is like the preceding, but entirely ſmooth. *Leaflets* ſix pair, with an odd one, ovato-lanceolate, bluntiſh. *Calyx* obſcurely toothed. Mr. Saliſbury recommends the ſeparation of theſe two laſt from *Sophora*, on account of their permanent *ſtamens;* but it ſeems to us that *S. japonica* connects them with the original ſpecies, both by that character, and ſomewhat of habit, or aſpect.

Section 2. *Cluſters lateral, ſhorter than the leaves.*

6. S. *macrocarpa*. Great-ſeeded Sophora.—Leaflets elliptic-oblong, nearly ſmooth. Cluſters axillary, very ſhort. Legume ſilky, two-edged, tumid, without wings.—Native of Chili, where it is commonly known by the name of *Mayo*. We received fine ſpecimens from the late abbè Cavanilles, in 1804. The *ſtem* is arboreous. *Branches* roundiſh, knotty; ſilky when young. *Leaves* deciduous, about a finger's length, compoſed of from ſix to nine pair of, not exactly oppoſite, obtuſe, rigid *leaflets*, three quarters of an inch long, beſides an odd one, all green; ſhining, and ſparingly downy, above; paler, and rather ſilky, beneath. *Cluſters* towards the ends of the branches, axillary, ſimple, compoſed of four or five large yellow *flowers*, whoſe partial ſtalks are about the length of the common one, all ſilky, as well as the *calyx*. *Stamens* occaſionally permanent. *Legume* from three to five inches long; when young compreſſed, two-edged, and finely ſilky; where the *ſeeds* ripen, they form large oval ſwellings, almoſt as big as a bullace plum, partly deprived of their downineſs, and marked with a ſlight ridge along each ſide, as in *S. tomentoſa*, but quite deſtitute of angles, wings, or other inequalities. In infloreſcence, habit, and aſpect of the *flowers*, this ſpecies accords exactly with all the following ones, while its *legume* is that of the original *Sophoræ*. We conceive, therefore, that it overſets the genus *Edwardſia*, to which, if that genus exiſts at all, the preſent plant ſhould belong, and yet its *legume* is neither quadrangular nor winged, nor is there any character in the fructification at all different from *Sophora*.

7. S. *nitida*. Silky-leaved Sophora.—Leaflets elliptic-oblong, ſilky on both ſides. Cluſters axillary, very ſhort. Legume hairy, with four prominent angles.—Gathered by Commerſon, in the iſle de Bourbon. An elegant ſilky *ſhrub* or *tree*. *Leaves* two or three inches long, compoſed of from eight to twelve pair of *leaflets*, half the ſize of the laſt, beautifully ſilky, as well as their ſtalks; brighter beneath. The *flowers* are paſt in our ſpecimen; their *ſtalks* are much like the laſt, but more hairy, with larger, more permanent, oppoſite *bracteas*. Half-ripe *legumes* about four inches long, rather ſlender, beaded, their four thick prominent angles much more hairy than the interſtices, which ſhould ſeem to become quite ſmooth as the oval parts, encloſing the *ſeeds*, are more enlarged.

8. S. *tetraptera*. Four-winged Sophora. Ait. ed. 1. v. 2. 43. Willd. n. 1. J. Mill. Ic. t. 1. Curt. Mag. t. 167. Lamarck f. 3. Roem. and Uſt. Mag. faſc. 12. t. 1. (Edwardſia grandiflora; Saliſ. Tr. of Linn. Soc. v. 9. 299. Ait. Hort. Kew. v. 3. 1.)—Leaflets elliptic-oblong, ſilky on both ſides. Cluſters lateral. Legume ſlightly hairy, with four membranous crenate wings.—Diſcovered in New Zealand, by ſir Joſeph Banks, and brought in 1772 to this country, where it thrives well againſt a ſouth or weſt wall, in the open air, with only the protection of a mat in winter, flowering about May or June. Few ſhrubs are more ornamental. The ſilky *leaves* are much like the laſt, but rather larger. *Flowers* about ſix together, in ſilky-ſtalked, drooping cluſters; each *flower* near two inches long. The brown *ſtalks* and *calyx* are ſtrikingly contraſted with the golden *petals*, whoſe ſtandard is ſhorter, and of a fuller yellow, than the reſt. *Legume* three or four inches long, each tumid part, where a ſeed is lodged, bordered, at each ſide of the ſuture, with two parallel wings, the whole legume being ſomewhat compreſſed, and not uniformly winged in four directions, like that of *Lotus tetragonolobus*. The baſe or tube of the *calyx* is, in this ſpecies, broader, or more dilated, than in moſt of the reſt, beſides having ten ribs. But we find it preciſely analogous to the ſame part in *S. tomentoſa*, and others, where it always has a different colour, texture, or appearance, from the limb.

9. S. *chryſophylla.* Golden-leaved Sophora. (Edwardſia chryſophylla; Saliſ. Tr. of Linn. Soc. v. 9. 299. t. 26. f. 1.)—Leaflets obovate, emarginate, ſilky. Cluſters lateral. Legume . . . . .—Gathered in the Sandwich iſlands, by Mr. Menzies. The *leaflets* are thrice as broad as in the foregoing; *flowers* yellow, about half the ſize of that ſpecies. Nothing is known reſpecting the *legume.*

10. S. *microphylla.* Small-leaved Sophora. Ait. ed. 1. v. 3. 43. Willd. n. 2. Lamarck f. 1. Jacq. Hort. Schoenbr. v. 3. 10. t. 269. (S. tetraptera; Forſt. Prodr. 32. Linn. Suppl. 230.)—Leaflets numerous, roundiſh-obovate, ſomewhat ſilky. Cluſters lateral. Legume with four membranous crenate wings.—Diſcovered by Banks, Forſter, and others, in New Zealand. Introduced in 1772 to the notice of Britiſh cultivators. It is uſually treated here as a greenhouſe ſhrub, though marked as hardy by Mr. Aiton, flowering in May and June. The younger Linnæus, like Forſter, confounded this with *S. tetraptera,* n. 8, though our native ſpecimen, from the latter, is marked *microphylla.* It differs eſſentially from *tetraptera,* though their *legumes* are ſimilar, in having *flowers* not above half ſo large, and eſpecially in the rounded figure, and ſmall ſize, of its numerous *leaflets,* whoſe ſilky pubeſcence, moſt conſpicuous on their under ſide, is ſilvery, not of a tawny or golden hue, even after long keeping.

For other ſpecies, formerly referred to this genus, ſee Ormosia and Podalyria.

Sophora, in *Gardening,* contains plants of the herbaceous, flowery, perennial, and ſhrubby exotic kinds, of which the ſpecies (as ſome have reckoned them) cultivated are, the wing-podded ſophora (S. tetraptera); the ſmall-leaved ſhrubby ſophora (S. microphylla); the fox-tail ſophora (S. alopecuroides); the blue ſophora (S. auſtralis); the dyer's ſophora (S. tinctoria); the white ſophora (S. alba); the downy ſophora (S. tomentoſa); the occidental ſophora (S. occidentalis); the ſhining-leaved ſophora (S. japonica); the vetch-leaved ſophora (S. capenſis); the golden-flowered ſophora (S. aurea); and the round-leaved ſophora (S. myrtillifolia.)

Method of Culture.—The firſt five ſorts are hardy, and may be increaſed by ſeeds, or parting the roots. The ſeeds ſhould be ſown in the ſpring, in pots of fine mould; and when the plants are come up, they ſhould be removed into ſeparate pots, till they have obtained ſufficient ſtrength, when they may be planted out where they are to grow. The roots may likewiſe, in many of the ſorts, be parted at the ſame ſeaſon, and planted in pots, or where they are to remain. The firſt and ſecond ſorts may alſo be raiſed from cuttings and layers, planted or laid down at the ſame ſeaſon. Theſe, when planted againſt a wall, ſo as to be protected from the froſt in winter, ſucceed very well.

But all the other ſorts are tender, and require the protection of the hot-houſe or ſtove. They are increaſed by ſowing the ſeed in the early ſpring, in pots filled with fine mellow light mould, and plunging them in the hot-bed under glaſſes, or in the bark-bed. When the plants have advanced a little in growth, they ſhould be removed into ſeparate pots, filled with ſoft loamy mould, being well watered, and replunged in the bark-bed till freſh rooted; being afterwards managed as other exotic ſtove plants, with but little water. They likewiſe ſometimes ſucceed by layers and cuttings, treated in the ſame manner.

It may be noticed, that the firſt ſorts afford variety in the borders, and among potted plants; and the latter in ſtove collections, where heat is required. Many of the tender ſorts are very elegant plants, proper for affording ornament and curioſity in ſuch ſituations.

SOPHRONISTÆ, σωφρονισται, among the Athenians, were ten officers, appointed to take care that the young men behaved themſelves with ſobriety and moderation.

SOPHRONISTERIUM, σωφρονιστηριον, among the Athenians, a houſe of correction, like our Bridewell.

SOPIANÆ, in *Ancient Geography,* a town of the Lower Pannonia, upon the route from Sirmium to Carnuntum, between Antiana and Manſuetianus, according to the Itinerary of Antonine.

SOPIO, a name uſed by ſome of the old writers for opium, from its ſoporific virtue.

SOPOLO, in *Geography,* a town of Turkiſh Albania; 32 miles S.S.E. of Valona.

SOPORARIÆ Arteriæ, a name given by ſome authors to the carotid arteries.

SOPORIFIC, or Soporiferous, a medicine that has the faculty of procuring ſleep. Such are opium, laudanum, &c.

The word is formed from the Latin *ſopor, ſleep.* The Greeks, in lieu of it, uſe the word *hypnotic.*

SOPOROUS, Sleepy, or *Drowſy diſeaſes,* a term by which medical writers expreſs the lethargy and coma, and ſome others even the carus and apoplexy.

SOPPAU, in *Geography,* a town of Sileſia, in the principality of Jagerndorf; 5 miles N. of Jagerndorf.

SOPPY, a town on the N.W. coaſt of the iſland of Morty. N. lat. 2° 40′. E. long. 128° 15′.

SOPRA, Ital. *above, upper:* as *nelle parte di ſopra,* in the upper parts; *di ſopra,* above; *contrapunto ſopra il ſoggetto,* counterpoint above the ſubject. See Soggetto.

SOPRANO, in *Italian Muſic,* means ſupreme, or the higheſt vocal part. Its clef is that of the tenor or C clef on the firſt line. Muſic for a ſoprano or treble voice in Italy, is always written in the C clef on the firſt line, thence called the ſoprano clef. The treble or G clef, in which we write vocal treble parts, is called by the Italians, *chiave di violino,* the violin clef, and only uſed for the higheſt parts of inſtrumental muſic.

SOPRON, in *Geography.* See Edenburg.

SOQUA, a town of the duchy of Warſaw; 60 miles N. of Warſaw.

SOR, a river of France, which runs into the Agout, ſix miles below Caſtres.

Sor. See Tsor.

SORA, in *Botany,* the name given by the people of Guinea to a kind of ſhrub which they uſe in medicine, boiling it in water, and giving the decoction in caſes of pain of any kind.

The leaves of this ſhrub are of the ſize and ſhape of thoſe of ſenna; they ſtand upon ſhort footſtalks, and are woolly underneath. Philoſ. Tranſ. No. 231.

Sora, in *Ancient Geography,* a town of Arabia Deſerta, on the confines of Meſopotamia. Ptolemy.—Alſo, a town of India, on this ſide of the Ganges, according to Ptolemy, who gives it the title of "Arcati Regia."—Alſo, the name of a town of Phœnicia. Steph. Byz.—Alſo, a town of Italy, in Latium, towards the N.E., upon the Lixis. According to Livy, it belonged to the Samnites.

Sora, in *Geography,* a town of Naples, in Lavora, the ſee of a biſhop, immediately under the pope; 31 miles N.N.W. of Sezza. N. lat. 41° 47′. E. long. 13° 36′.

SORACTES, in *Ancient Geography,* mountains of Italy, in Etruria, on the confines of the country of the Faliſci, and in the vicinity of the Tiber.

SORÆ, a people of India, who dwelt in the vicinity of Carmania and Gedroſia, near the river Caberon, according to Pliny.—Alſo, a people of India, on this ſide of the Ganges, counted among the Nomades by Ptolemy, who places them between the mountains Bitigus and Diſathrus.

SORÆI, a people of Africa, in Mauritania Cæſarienſis. Ptolemy.

SORAGNA, in *Geography*, a town of the duchy of Parma; 13 miles N.N.W. of Parma.

SORAMIA, in *Botany*, Aubl. Guian. t. 219. Juſſ. 433. See Mappia.

SORANUS, in *Medical Hiſtory*, one of the moſt able of the phyſicians of the *methodic* ſect, according to the opinion of Cælius Aurelianus, and the one who put the finiſhing hand to that ſyſtem, was a native of Epheſus. His father's name was Menander, and that of his mother Phœbe. He ſtudied medicine, and afterwards practiſed it at Alexandria, but at length he ſettled at Rome, and was in conſiderable repute in that metropolis in the reigns of Trajan and Adrian. His character, indeed, ſeems to have been highly eſtimated; for he was in favour with all parties. Even Galen, who was violent in his oppoſition to the *Methodiſts*, and abuſed Theſſalus with ſome acrimony, ſpeaks favourably of the knowledge of Soranus, and bears his teſtimony, from experience, to the efficacy of ſome of his remedies. Soranus compoſed ſeveral works, none of which have come down to us in their proper form; but as Cælius Aurelianus, in his treatiſe “De Morbis Acutis et Chronicis,” every where acknowledges himſelf to be a tranſlator from the Greek of Soranus, that work may be conſidered as in ſubſtance the production of the latter.

Some confuſion prevails among medical writers, who miſtake Soranus the Methodiſt for two other phyſicians of the ſame name. The firſt of theſe was alſo a native of Epheſus, but poſterior to the Methodiſt. He was the author of a good treatiſe on the diſeaſes and organs of generation of women, which was printed at Paris in 1556, under the title of “De Utero et Muliebri pudendo libellus,” together with ſome pieces of Rufus, the Epheſian. This fragment is ſo accurate in point of anatomical deſcription, as to leave a regret that the other writings of this phyſician are loſt. The third of theſe phyſicians of the name of Soranus, was ſurnamed *Melotas*, from the town in Cilicia, where he was born. There is, however, no very authentic record of him extant; and the only work aſcribed to him, which is entitled “Iſagoge ſaluberrima in Artem medendi,” and was printed at Baſle, 1528, and Venice, 1547, is maintained by Voſſius to be the work of a poſterior Latin writer, and not of any of the three perſons named Soranus. See Le Clerc, Hiſt. de la Med. Eloy Dict. Hiſt.

SORARUM, in *Geography*, a town of Hindooſtan, in the circar of Cicacole; 10 miles W. of Coſſimcotta.

SORAS, a town and juriſdiction of Peru; 60 miles S. of Guamanga.—Alſo, a town of Italy, in the Feltrin; 8 miles W.S.W. of Feltri.

SORAU, or Zyory, a town of Sileſia, in the principality of Ratibor; 18 miles E. of Ratibor. N. lat. 50° 1′. E. long. 18° 40′.

SORAW, or Zarow, a town of Luſatia, and one of the moſt ancient towns in the country, ſurrounded with walls in the year 1207. It has manufactures of cloth, and a conſiderable trade in linen and yarn; 25 miles S.S.E. of Guben. N. lat. 51° 37′. E. long. 15° 10′.

SORBA, a town of France, in the department of Jemappe, and chief place of a canton, in the diſtrict of Corté. The canton contains 2000 inhabitants.

SORBAIT, Paul de, in *Biography*, a phyſician of eminence, was a native of Hainault, in the Low Countries. Having finiſhed his courſes of claſſical and philoſophical ſtudies, he commenced that of medicine, which he appears to have concluded by taking the degree of doctor in that faculty at Vienna, where he ultimately ſettled. He obtained a high reputation for medical ſkill and erudition; and, in 1655, was appointed to the principal profeſſorſhip of medicine in the univerſity of that metropolis, the duties of which he executed with conſiderable celebrity, until the year 1679. While he was engaged in his courſe of this year, he was honoured with the appointment of phyſician to the dowager empreſs Eleanor, and at the concluſion of it, relinquiſhed altogether his academical avocations. His merits were ſtill farther rewarded by the office of counſellor and ſuperintendant of the public health, and by his elevation to the dignity of a knight of the kingdom of Hungary. He died in April 1691, at an advanced age. He left ſeveral works, namely, a body of medical practice, firſt publiſhed at Nuremberg, in 1672, folio, with the title of “Univerſa Medicina, tam Theorica quam Practica, nempè Iſagoge Inſtitutionum Medicarum et Anatomicarum, &c.” This work was republiſhed at Vienna in 1680, and again after his death, in 1701, with the new title of “Praxeos Medicæ auctæ, et a plurimis typi mendis ab ipſo Auctore caſtigatæ, Tractatus VII. &c.” “Nova et aucta Inſtitutionum Medicarum Iſagoge,” 1678, 4to. “Commentaria et Controverſiæ in omnes Libros Aphoriſmorum Hippocratis,” 1680. In the preceding year he publiſhed an account of the plague, which had committed dreadful ravages in Vienna, having deſtroyed, he affirms, not leſs than 76,921 perſons. Its title was “Conſilium Medicum, ſive Dialogus Loimicus de Peſte Viennenſi,” 1697; and he publiſhed the ſame work, in German, in 1680. He was author alſo of “A Treatiſe on Midwifery,” in the German language. Eloy Dict. Hiſt. de la Med.

SORBECKE, in *Geography*, a river which riſes in Weſtphalia, and runs into the Rhur, about two miles S. of Neheim.

SORBELLONI, in *Biography*, a ſecond rate Italian opera ſinger in *ſoprano*, who arrived here in 1761; and who, from the mere ſweetneſs of his voice, free from vulgarity, was always much applauded. He was here at the ſame time as Paganini, and performed the part of ſerious man in the burlettas of the time.

SORBIERE, Samuel, was born in 1615, at St. Ambroix, in the dioceſe of Uſez. He was educated by his maternal uncle, an eminent Calviniſt miniſter at Niſmes. He came to Paris in 1639, and being diſguſted, for ſome reaſons not now known, with the ſtudy of theology, he took up that of medicine. In 1642 he went to Holland, where, beſides purſuing his medical ſtudies, he materially aſſiſted in the tranſlation of Camden's Britannia, and alſo More's Utopia. He married, in Holland, the daughter of one of his townſmen, and went to Leyden, with the intention of ſettling in his profeſſion. In 1648 he publiſhed, under his own name, a French verſion of a treatiſe of Gaſſendi, entitling it “Diſcours ſceptique ſur le Paſſage du Chyle, et le Mouvement du Cœur.” Returning to France in 1650, he was made principal of the college of Orange, and there printed a Diſcourſe on the true cauſe of the troubles of England, and a letter on the deſigns of Cromwell. He conformed to the Catholic religion in 1653, after which his life was chiefly ſpent as an author, with a view, it is ſaid, of attempting to obtain penſions, in which he was very ſucceſsful, having laid under contribution cardinal Mazarin, Lewis XIV., and the popes Alexander VII. and Clement IX. He viſited England in 1664, and on his return he publiſhed an account of what he had obſerved, which was ſo free in its ſtrictures, that he was for a time exiled by a *lettre de cachet*. Sorbiere was likewiſe author of a work entitled “Lettres et Diſcours ſur divers Matières curieuſes,”

curieuſes," which contributed to his temporary reputation. He died in 1670, and a Sorberiana was publiſhed after his death, containing ſentiments ſuppoſed to have dropt from him in converſation. His writings exhibit a cauſtic and ſatirical ſpirit, and the learning which they diſplay is neither original nor ſolid. He was intimately connected with Hobbes and Gaſſendi, on whom he impoſed himſelf as a profound thinker.

SORBIODUNUM, in *Ancient Geography*. See Sorviodunum.

SORBOE, in *Geography*, a ſmall iſland in the North ſea, near the coaſt of Norway. N. lat. 59° 5'.

SORBOLE, a town of Sweden, in Weſt Bothnia; 10 miles S.W. of Umea.

SORBONNE, Robert de, in *Biography*, founder of the famous theological college which bears his name, was born in 1201, of an obſcure family at Sorbon, in the dioceſe of Rheims. Being educated at Paris, and having taken his degree of doctor, he devoted himſelf to preaching, in which he became ſo celebrated, that the king made him his chaplain and confeſſor. Having become a canon of Cambray in 1251, the recollection of the difficulties which he had experienced in the courſe of his own ſtudies, ſuggeſted to him a plan for facilitating to poor ſcholars the means of proceeding to graduation. This was to form a ſociety of ſecular eccleſiaſtics, who, living in common, and provided with a regular maintenance, ſhould read lectures gratuitouſly. With the aſſiſtance of his friends, he founded the college called the Sorbonne, which was particularly conſecrated to the ſtudy of theology, and its conſtitution has ſerved as a model for that of all colleges ſince erected in that country. Sorbonne afterwards added to this foundation a college for the languages and philoſophy, under the name of the College of Calvi, or the Little Sorbonne. He was made canon of Paris in 1258, and roſe to ſuch a height of reputation, that princes looked to him on many important occaſions as the arbitrator in their diſputes. He died in 1274, at the age of 73, and left conſiderable property to his college. He was author of ſeveral works on theological ſubjects, which are preſerved in MS. in the library of the great college of which he was the liberal founder.

Sorbonne, or Sorbon, the houſe or college of the faculty of theology, eſtabliſhed in the univerſity of Paris.

It was founded in 1256, by St. Louis, or rather by Robert de Sorbonne, his confeſſor and almoner; firſt canon of Cambray, and afterwards of the church of Paris; who gave his own name to it, which he himſelf took from the village of Sorbon, or Serbon, in the department of the Ardennes, near Sens, ſix miles N. of Rethel, where he was born.

The foundation was laid in 1250, afterwards the king gave him all the houſes he had in the ſame place, in exchange for ſome others in another.

The college has been ſince magnificently rebuilt by the cardinal de Richelieu. The deſign of its inſtitution was for the uſe of poor ſtudents in divinity.

There were lodgings in it for thirty-ſix doctors and bachelors of the houſe; who were ſaid to be of the *ſociety of the Sorbonne*. Thoſe admitted into it without being doctors were ſaid to be of the *hoſpitality of the Sorbonne*. Six regent doctors held lectures every day, for an hour and half each: three in the morning, and three in the afternoon.

Sorbonne has been alſo uſed in the general for the whole faculty of theology at Paris, becauſe the aſſemblies of the whole body were held in the houſe of the Sorbonne: and becauſe the bachelors of the other houſes of the faculty, as the houſe of Navarre, &c. came thither to hold their *ſorbonnique*, or act, for being admitted doctors of divinity.

SORBUS, in *Botany*, a word uſually derived by critics from *ſorbeo*, to ſuck in; becauſe its fruit *Sorbum*, the Sorb-apple, or Service, ſee Service-tree, is not eatable till the pulp becomes quite ſoft, ſo as to be ſucked rather than bitten. De Theis, however, goes to the recondite ſources of Celtic learning for its origin; *Sormel*, the name of the fruit in that language, being, as he ſays, formed of *ſor*, harſh or rude, and *mel*, an apple.—Linn. Gen. 250. Schreb. 338. Willd. Sp. Pl. v. 2. 1008. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 204. Juſſ. 335. Lamarck Illuſtr. t. 434.—Claſs and order, *Icoſandria Trigynia*, Linn. Nat. Ord. *Pomaceæ*, Linn. *Roſaceæ*, Juſſ.

This genus, conſiſting, in moſt authors, of three ſpecies, *S. aucuparia*, *hybrida*, and *domeſtica*, we refer, without ſcruple, as in the *Flora Britannica*, to Pyrus; ſee that article, n. 24, 25, 26. See alſo Mespilus.

Sorbus, in *Gardening*, contains plants of the ornamental tree kind, among which the ſpecies cultivated are, the mountain-ſervice, mountain-aſh, quicken-tree, roan-tree (S. aucuparia); the true ſervice, or ſorb (S. domeſtica); and the baſtard ſervice, or mountain-aſh (S. hybrida).

In the firſt ſort the leaves make a pretty variety, when mixed with other trees in plantations: it is alſo handſome when in flower, and in the autumn, when in fruit; but the blackbirds and thruſhes are ſo fond of it, that they devour it before it is well ripe.

In the ſecond ſort there are varieties in the fruit; as with apple-ſhaped fruit; with pear-ſhaped fruit; with oval fruit; with turbinated fruit; and with compreſſed fruit.

Method of Culture.—Theſe plants are all capable of being raiſed from ſeed, and alſo by layers; but the firſt is the beſt method. The ſeeds, when well ripened in the autumn, ſhould be ſown on ſmall beds of light fine ground in the nurſery, either in drills or over the ſurface, covering them in to the depth of about an inch. When the plants riſe in the following or ſecond ſpring, they ſhould be kept clear from weeds, and when of a year's growth, be planted out in nurſery rows, to remain till of a proper ſize for planting out. But the ſecond ſort is ſometimes ſown in large pots, and forwarded in a hot-bed, ſo as to be ſooner fit for planting out in nurſery rows, as in one year, or a ſhort ſpace of time.

In the layer method, ſome of the beſt trees ſhould be cut down near to the ground while young, by which ſhoots will ſoon be made and ſent off, which ſhould be laid down in the uſual way in the autumn or ſpring ſeaſons, where they readily ſtrike root, and become proper for being planted out in nurſery rows in about one year.

In order to continue any particular variety, this method muſt conſtantly be adopted. Alſo, in cultivating the ſecond ſort, for the purpoſe of fruit, the beſt method is by grafting or budding upon ſtocks of any of the ſorts raiſed as above, or upon pear-ſtocks.

Theſe trees, in rearing, ſhould be trained for ſtandards, each with a ſingle upright ſtem, in the nurſery, till from three to ſix or eight feet high, when they are proper for any plantation, and may be tranſplanted as required. And they may be introduced in any large ſhrubbery or other ornamental plantation, and in thoſe of foreſt-trees. Some of the domeſtic ſervice-tree ſort may alſo be introduced as fruit-trees in gardens and orchards, principally as ſtandards, but occaſionally in eſpaliers, &c. in both of which modes they ſhould be planted and managed as apple and pear-trees, permitting the ſtandards to ſhoot freely above into full heads; the others being regulated according to their order of training. They will produce plentiful crops of fruit annually, after ſome time, to gather in autumn. In gathering of which for the table, it is proper to lay ſome in the fruitery, or other place, a little time, to mellow and become ſoft and tender; in which ſtate it is eatable, and of an agreeable taſte and flavour.

Some of theſe ſorts of trees, as the firſt and laſt kinds, are very ornamental in pleaſure-ground plantations, and large ſhrubberies, both in their leaves and fruit. The other ſort may alſo be occaſionally introduced with good effect in particular ſituations.

SORCERER'S ISLAND, in *Geography*, a ſmall iſland in the Atlantic, near the coaſt of Africa, where the Negroes come yearly to ſacrifice to their deities, near the mouth of the Rio Grande.

SORCERY, the crime of witchcraft, or divination, by the aſſiſtance of evil ſpirits. See MAGIC and MAGICIAN.

Some hold ſorcery to be properly what the ancients call *ſorti-legium*, or divination by means of *ſortes*, or *lots*. Lord Coke, 3d Inſt. fol. 44, deſcribes a ſorcerer, *qui utitur ſortibus, et incantationibus dæmonum*.

Sorcery is pretended to have been a thing formerly very common; at leaſt the credulity of thoſe ages made it paſs for ſuch; and people ſuffered frequently for it.

This ſuppoſed crime was made felony by 33 Hen. VIII. c. 8, and 1 Jac. I. c. 12; but this abſurd law was very properly repealed by an act of George II. See CONJURATION.

SORCY, in *Geography*, a town of France, in the department of the Meuſe, ſituated on the Meuſe; 3 miles S.E. of Commercy.

SORDE, or SORDES, a town of France, in the department of the Landes, on the gave of Oleron; 9 miles E. of Bayonne.

SORDES, a term applied to the matter diſcharged from ulcers in horſes, when it is rather viſcid or glutinous. This matter is frequently of a browniſh-red colour, ſomewhat reſembling the grounds of coffee, or grumous blood mixed with water. *Sordes*, *ſanies*, and *ichor*, are all of them terms which imply a diſcharge much more fetid than purulent matter, and none of them are altogether free from acrimony; but that which is generally termed *ichor* is by much the moſt acrid of them, being frequently ſo ſharp and corroſive, as to deſtroy large quantities of the neighbouring parts.

SORDINO, Ital., SOURDINE, Fr., a mute, or little machine placed on the bridge of a violin or violoncello to enfeeble or deaden the tone, by impeding the vibration of the whole inſtrument. The French never uſe this machine, and the Italians but ſeldom, at preſent.

SORDITIES, in *Surgery*, putrid pus of bad quality.

SORDUN, in *Geography*, a town of France, in the department of the Seine and Marne; 3 miles S.E. of Provins.

SORE, a town of France, in the department of the Landes, and chief place of a canton, in the diſtrict of Mont-de-Marſan; 27 miles N. of Mont-de-Marſan. The place contains 1450, and the canton 3409 inhabitants, on a territory of 420 kiliometres, in 4 communes.

SORE, among *Sportſmen*, denotes a buck of the fourth year.

SOREL, a buck of the third year.

SOREL, in *Botany*. See SORREL.

SOREL, in *Geography*, a cape on the N. coaſt of the iſland of Jerſey; 7 miles N.E. of St. Helier.

SORELLE, a town of Lower Canada, ſituated at the mouth of a river of the ſame name, which runs from lake Champlain into the St. Lawrence. It was laid out about the year 1787, and on an extenſive plan, with very wide ſtreets, and a large ſquare; but at preſent it contains only 100 houſes, which are all very indifferent, and widely ſeparated from one another. This is the only town on the St. Lawrence, between Montreal and Quebec, in which Engliſh is the predominant language. The inhabitants conſiſt principally of loyaliſts from the United States, who took refuge in Canada. The chief buſineſs carried on here is that of ſhip-building; ſeveral veſſels are annually launched from 50 to 200 tons burthen, which are floated down to Quebec, and there rigged. The river of Sorelle is deep at its mouth, and affords good ſhelter for ſhips from the ice, at the breaking up of winter: it is not navigable far beyond the town, even in boats, on account of the rapids; 24 miles N.N.E. from Montreal. Weld's Travels, vol. i.

SORENTO, or SORRENTO, a ſea-port town of Naples, in Principato Citra, ſituated on the brink of the ſteep rocks that overhang the bay of the ſame name, and preſenting an enchanting aſpect. The mountains of Vico and Maſſa, between which it lies, ſhelter it from the W. and S. winds. Its ſtreets are narrow; but this is no inconvenience in a warm climate, where carriages are not uſed, nor any communication with the metropolis practicable by land. Of all the places in the kingdom, this enjoys the moſt delightful climate, for which it was renowned in ancient times. Silius Italicus extols its ſoft and wholeſome zephyrs: "Zephyro Suorentum molle ſalubri." At preſent it enjoys ſhady groves, excellent water, fruit, fiſh, milk, butter, the fineſt veal, the beſt wine, and every neceſſary of life at an eaſy rate. Its population conſiſts of about 15,000 inhabitants, being half the population of the whole plain. Theſe are goldſmiths, mariners, or fiſhermen. The women are employed in breeding ſilk-worms, and weaving the ſilk which they draw from them. It is an archiepiſcopal ſee, of which the biſhops of Stabia, Vico, Equenſe, and Maſſa, are ſuffragans. Some abbies are alſo ſubſervient to it.

According to Hyginus, it was built by the Greeks; and was called Syrenetum, or Surenetum, from its having been the reſidence of the ſyrens Leucoſia and Ligia. However this be, it was anciently the abode of the Oſci, Opici, and Picentini, whoſe capital it was, and afterwards a Roman colony, and a municipal city, as we may conclude from a multitude of antique marbles. Its numerous ruins of edifices ſhew that the town is much reduced from its ancient ſtate. It was formerly adorned with ſeveral magnificent temples, among which were thoſe of Juno and Diana; but the moſt ſplendid of them was that built by Pollius, in honour of Hercules, and which Statius has depicted in all the charms of poetry. The place where this temple ſtood is now called corruptly Polo, and ſome traces are ſtill ſeen of thoſe of Ceres, Neptune, and Apollo. Beſides the fruits and wines for which Sorrento is famous, it was alſo celebrated among the ancients for its beautiful earthen veſſels, eſpecially as goblets or drinking cups. Pliny very much applauds them, and Martial prefers them to thoſe of the moſt valuable materials, and of the moſt exquiſite workmanſhip. Sorrento values itſelf upon having been the birthplace of the celebrated grammarian L. Craſſitius Paſides, mentioned by Suetonius in his treatiſe "De illuſtribus Grammaticis;" of the learned Bernardin Rota; and of the renowned Torquato Taſſo; 15 miles S. of Naples. N. lat. 40° 40′. E. long. 14° 24′.

The bay of Sorrento is three miles wide: a ſemicircular chain of woody mountains incloſes a rich and beautiful plain, rather ſloping towards the ſea, full of white buildings peeping out of the groves. This creſcent terminates in a ſtraight line to the ſea, by a bold coaſt of black perpendicular rocks. This probably formed a portion of a circle, half of which broke off and ſunk into the waves, and probably the whole was once the crater of a volcano. The whole ſoil of the plain is cineritious, and its rocks conſiſt of a ſtrong blue lava, except near the eaſt end, where they are of a ſofter piperino kind. The encircling mountains are compoſed of regular calcareous layers; and the materials of the lower ground are without doubt volcanical.

SOREX, or Shrew, in *Natural Hiſtory*, a genus of the Mammalia Feræ claſs and order, of which the following is the generic character: there are two upper fore-teeth, which are long and bifid; the lower fore-teeth are from two to four; the intermediate ones are ſhorter; there are ſeveral tuſks on each ſide; the grinders cuſpidate. (See the article Shrew.) Seventeen ſpecies are enumerated in Gmelin's laſt edition of the Linnæan genera, which are as follow.

Species.

Cristatus; Creſted Shrew. The noſtrils in this ſpecies are caruncalate; the tail is ſhort. It inhabits North America. The whole animal is four inches long, and the tail an inch and a quarter: it feeds on roots, and reſembles the mole in its face and ſnout.

Minutus; Minute Shrew. The ſnout of this ſpecies is very long, and it has no tail. It inhabits Siberia, in moiſt woods, under the roots of trees: it makes its neſt of lichen, collects ſeeds, runs and burrows quickly; it bites, has the voice of a bat, and weighs about a drachm.

Aquaticus; Aquatic Shrew. In this ſpecies the hind-feet are palmate; fore-feet are white; the tail is ſhort and white. It is an inhabitant of North America, and is the ſize of a mole.

Moschatus. Feet palmate, tail flattened, thickeſt in the middle. This is called the muſky ſhrew; it inhabits about the lakes of Volga and Tanais; burrows under the banks, with an entrance into the water; feeds on flags and fiſh; the body of the animal is ſeven inches long, and the tail is eight.

* Bicolor; Water Shrew. The tail of this ſpecies is of the mean length; it is nakediſh; the body is blackiſh, beneath it is cinereous; the toes are fringed. It inhabits Europe and Siberia, near ſwamps and rivers; ſwims eaſily, often under water: the female has ten teats, and brings forth nine young at a time; it makes a noiſe like the chirp of a graſshopper; the body of the animal is four inches long, and the tail two.

Murinus; Murine Shrew. The tail is of a middle length; the body is brown, feet and tail cinereous. It inhabits Java, and is the ſize of a mouſe.

* Araneus; Fetid Shrew. The tail of this ſpecies is of the middle length; the body beneath is whitiſh. It inhabits almoſt every part of Europe, and in the northern climates of Aſia; it lives in old walls, ſtables, yards, granaries, out-houſes, ſwamps, and pools; it feeds on corn and inſects; it ſmells of muſk; is killed, but not eaten, by cats; the voice is ſhrill; it runs much ſlower than a mouſe; brings five or ſix young ones in ſpring and ſummer; it is ſeldom ſo long as three inches. There are two varieties. 1. Head, and upper parts, duſky; ſides browniſh ruſty. This is found in Hudſon's Bay and Labrador. 2. The upper parts are of a duſky grey, and underneath the animal is of a yellowiſh-white.

Surinamensis; Surinam Shrew. The tail of this ſpecies is half as long as the body; the body above is cheſnut, beneath white and yellowiſh-grey. It is found, as its ſpecific name denotes, at Surinam.

Pusillus; Timid Shrew. Ears rounded; tail ſhort, a little fringed at the ſides. It inhabits the northern parts of Perſia, in holes which it burrows; it is three inches and a half long; the body is of a dark grey above, and the belly is paler.

Brasiliensis. The body of this ſpecies is brown, the back is black, with three ſtripes. It inhabits Braſil, is about five inches long, with a tail of two inches in length.

Exilis. The tail of this is very thick in the middle, tapering to each end. It inhabits Siberia; it is the ſmalleſt of quadrupeds, ſcarcely weighing half a drachm; it is like, though of a darker colour, the S. araneus.

Cæruleus; Blue Shrew. The tail is of a mean length; the upper parts are of a pale blue; the belly is lighter; the legs and feet are white. It inhabits Java, and the other Eaſt Indian iſlands, feeds on rice, ſmells ſtrongly of muſk, is eight inches long, with a tail about half that length.

Mexicanus: Mexican Shrew. The tail is ſhort; the fore-feet are three-toed; the hind-feet have four toes. It is found in New Spain; burrows in vaſt numbers, feeds on roots and ſeeds; the fleſh is good; it is about nine inches long.

Albipes; White-footed Shrew. Tail ſlender, hairy; upper parts duſky-aſh; feet, belly, and teeth, white.

Quadri-caudatus; Square-tailed Shrew. The tail, as its ſpecific name denotes, is ſquariſh; the head and upper parts are of a duſky-aſh; the belly is paler; the fore-teeth are brown.

Luri-caudatus; Carinate Shrew. The tail is taper, keeled underneath; head and upper parts duſky-aſh, belly whitiſh; fore-teeth brown, a white ſpot behind each eye.

Unicolor. The tail is compreſſed at the baſe; the body is of an uniform duſky-aſh. It is obſerved by Gmelin, that the laſt four, deſcribed as diſtinct ſpecies, are probably only varieties of the S. araneus. They are all found near Straſburg.

SOREY, in *Geography*, a town of France, in the department of the Meuſe; 3 miles S.S.E. of Commercy.

SOREZE, a town of France, in the department of the Tarn; 12 miles S.S.W. of Caſtres.

SORG, a town of Germany, in the principality of Anſpach, on the Schwarzach; 8 miles E. of Schwabach.

SORGANO, a town of the iſland of Sardinia; 38 miles E. of Boſa.

SORGE, George Andreas, in *Biography*, a voluminous writer on muſic, and a compoſer, born in 1703, and who died in 1778. In Gerber there is a liſt of his works.

SORGENFREY, or Sans Souci, in *Geography*, a town of Denmark, in the iſland of Zealand, with a royal palace; 6 miles N. of Copenhagen.

SORGHUM, in *Botany*, a name of oriental or barbarous origin, but venerable for its antiquity.—"Perſ. Ench. v. 1. 101." Purſh v. 1. 78. (Sorgum; Mich. Gen. 35. Mieg. Act. Helvet. v. 8. 131. Holcus; Brown Prodr. Nov. Holl. v. 1. 198.)—Claſs and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume of two ovate, concave, coriaceous, unequal valves, inflexed at the margin, ſingle-flowered. *Cor.* of two membranous, ovato-lanceolate, rather unequal valves, hairy at the edges; the innermoſt rather the ſmalleſt, cloven, bearing from its fiſſure a twiſted awn, twice the length of the glume itſelf. Nectary a thin, awl-ſhaped, villous ſcale. *Stam.* Filaments three, capillary; anthers cloven at each end, prominent. *Piſt.* Germen ovate, poliſhed; ſtyles two, capillary, ſhort, ſpreading; ſtigmas oblong, feathery. Some flowers, elevated on ſtalks, have neither awn nor piſtil. *Peric.* none, except the permanent, hardened, cloſed calyx. *Seed* ſolitary, oval, tumid, concealed in the hard poliſhed calyx, out of which the awn of the corolla projects.

Eſſ. Ch. Calyx of two valves, ſingle-flowered. Corolla of two valves; the inner one cloven and awned. Nectary villous. Seed encloſed in the hardened calyx. Some flowers male, ſtalked, without an awn.

We have under the article Holcus adverted to the preſent genus, which requires to be ſeparated therefrom, and is in itſelf important, on account of its economical uſes. What are its genuine ſpecies, we do not completely undertake to determine, nor how far thoſe which are deſcribed are diſtinct, authors having been obliged to recur to *colour* in their definitions. "They are annual graſſes, of quick growth, and of a very large bulk, abounding with ſaccharine juice, as much as the ſugar-cane, at leaſt in Italy." Profeſſor Arduino ſhewed the writer of this, at Padua in 1787, good ſugar and treacle procured from his *Holcus Cafer*, hereafter mentioned. See Sm. Tour on the Continent, ed. 2. v. 3. 10. The ſtalks of the ripe panicles of ſome of the ſpecies make brooms, or even carpet and clothes-bruſhes of a very good quality. The following will ſerve to exemplify the genus in queſtion.

S. *Dora.* Common Indian-millet. (Holcus Dora; Mieg. Act. Helvet. v. 8. 125. t. 4. f. 3. Holcus Sorghum; Linn. Sp. Pl. 1484. Willd. Sp. Pl. v. 4. 929. Ait. Hort. Kew. v. 5. 430. Arduin. Olc. o Sorg. 19. t. 4. f. 1. Milium indicum; Matth. Valgr. v. 1. 370.)—Panicle ovate, compact, erect. Glumes downy. Seeds ſlightly compreſſed.—Native of the Eaſt Indies. Cultivated in the ſouth of Europe. The *root* is annual, conſiſting of innumerable fibres. *Stem* erect, round, jointed, leafy, from ſix to ten feet high, as thick as the finger or thumb. *Leaves* ſheathing, reed-like, lanceolate, ſmooth, with a ſtrong mid-rib, and many fine lateral, oblique, parallel ones. *Panicle* terminal, from four to twelve inches long, very much branched, cloſe, of innumerable downy *flowers*, on zig-zag or curved ſtalks. *Seeds* roundiſh, various in colour, uſually yellow or reddiſh. This is the moſt general ſpecies, under which indeed many of the reſt have been confounded; but ſome of them, by their ſuperior merits, have ſuperſeded it in cultivation.

S. *bicolor.* Two-coloured Indian-millet. (Holcus bicolor; Linn. Mant. 301. Willd. Sp. Pl. v. 4. 929. Ait. Hort. Kew. v. 5. 430. Arduin. Olc. o Sorg. 29. t. 6. H. Sorghum; Mieg. Act. Helvet. v. 8. 129. t. 4. f. 4?)—Panicle erect, ſomewhat lobed. Glumes ſmooth, black. Seeds globoſe, white.—Said to be a native of Perſia. Sufficiently diſtinct from the former, by the above characters.

S. *cernuum.* Drooping Indian-millet. (Holcus cernuus; Willd. Sp. Pl. v. 4. 930. Arduin. Olc. o Sorg. 14. t. 3. f. 1, 2.)—Panicle compact, curved downward as it ripens. Glumes downy. Seeds globoſe.—Cultivated in Arabia, Syria, and various parts of the Levant, being probably a native of India. It is remarkable for its deflexed, or pendulous *panicle* of *ſeed*, whoſe ſtalk cannot be made ſtraight without breaking. The *ſtem* is five or ſix feet high. *Leaves* ſmooth. *Seeds* very white, ſcarcely compreſſed.

S. *caffrorum.* Caffres Indian-millet. (Holcus caffrorum; Thunb. Prodr. 20. Willd. Sp. Pl. v. 4. 930. H. Cafer; Arduin. Olc. o Sorg. 5. t. 1.)—Branches of the panicle ſpreading every way, deflexed. Glumes downy. Awns deciduous. Seeds globoſe.—Native of the Cape of Good Hope. Rather larger than moſt of the preceding, with a ſpreading, drooping-branched *panicle*. *Seeds* more expoſed than in the others. Profeſſor Arduino recommends this much for culture, on account of its abundant crop; the goodneſs of the grain for poultry; and the copious ſaccharine juices of the *ſtems*. We preſume his plant and Thunberg's to be the ſame, but have no proof.

S. *ſaccharatum.* Yellow-ſeeded Indian-millet. Purſh n. 1. (Holcus ſaccharatus; Linn. Sp. Pl. 1484. Willd. Sp. Pl. v. 4. 930. Ait. Hort. Kew. v. 5. 430. Arduin. Olc. o Sorg. 22. t. 4. f. 2. Mieg. Act. Helvet. v. 8. 119. t. 4. f. 1. Sorgum; Rumph. Amboin. v. 5. 194. t. 75. f. 1.)—Panicle erect, with ſlender, drooping, lax branches. Glumes hairy. Male flowers very few, withering.—Native of the Eaſt Indies. The more diſperſed *flowers*, on the long, ſpreading, drooping, whorled branches of the *panicle*, readily mark this ſpecies.

S. *nigrum.* Coal-black Indian-millet. (Holcus niger; Arduin. Olc. o Sorg. 20. t. 9.)—Panicle ovate, erect, with ſpreading denſe branches. Glumes and ſeeds black.—Nothing is ſaid of the native country, or particular qualities, of this ſpecies, which is one of the largeſt of the genus. The *leaves* are long and broad, conſpicuous for their white rib. *Panicle* ſomewhat pyramidal, not near ſo denſe as that of the firſt ſpecies, but the *flowers* are thickly ſet on its ſpreading, ſlightly deflexed, branches.

SORGUE, or *Pont de Sorgue*, in *Geography*, a town of France, on the river Sorgue; 6 miles from Avignon.—Alſo, a river of France, which riſes from the fountain of Vaucluſe, and runs into the Rhone, by ſeveral mouths, at and near Avignon.

SORI, a town of the Ligurian republic; 9 miles S.E. of Genoa.

SORIA, a town of Spain, in Old Caſtile, near the ſource of the Duero, built near the ruins of the ancient Numantia. This town, which ſuffered much during the Mooriſh wars, was repeopled in the beginning of the 12th century, by order of Alonſo, king of Caſtile; 116 miles N.N.E. of Madrid. N. lat. 41° 47′. W. long. 2° 35′.

SORIANG, a river on the W. coaſt of the iſland of Celebes, which runs into the ſea, S. lat. 3° 9′. E. long. 119° 48′.

SORIANO, Francesco, in *Biography*, a great canoniſt, and critic of the muſic of his time, was maeſtro di cappella of St. Peter's church at Rome, and in 1610 publiſhed one hundred and ten canons upon the chant to the hymn "Ave Maris Stella," for three, four, five, ſix, ſeven, and eight voices. Reſolutions of theſe canons in ſcore, with remarks, by Zacconi, 1625, in manuſcript, were in the poſſeſſion of the late reſpectable theoriſt and hiſtorian, P. Martini, who, among his other muſical curioſities, communicated to us this manuſcript, which impreſſed us with a much higher opinion of the patience than the genius of Soriano. Few maſters, except himſelf, could perhaps have compoſed theſe canons, but many muſt have thought that the loſs to muſic would not have been very great, if they had never been compoſed. Baptiſt Doni, an enemy to learned muſic, and a great advocate for the recitative and melodies for a ſingle voice, which were now advancing into favour, ſays (Tratt. della Muſ. Scenica, Op. omn. tom. ii. p. 129.) that though Soriano was generally allowed by muſicians to be a learned contrapuntiſt, he never had genius ſufficient to invent a ſingle air that was beautiful or pleaſing; on which account he applied himſelf to the compoſition of elaborate fugues and canons: as in poetry, thoſe who have no original ideas or invention can write acroſtics and anagrams, by which they become only rhymers, not poets; ſo canoniſts ſhould be called contrapuntiſts, not muſicians.

Soriano, in *Geography*, a town of the Patrimonio; 6 miles E.S.E. of Viterbo.—Alſo, a town of Naples, in Calabria Ultra; 6 miles E.S.E. of Mileto.

SORIBOA, a town of Peru, in the dioceſe of Truxillo, and juriſdiction of Chacapoyas.

SORICINA, a town of Italy, in the department of the Upper Po; 12 miles N. of Cremona.

SORIGO, a town of Italy, in the department of the Lario; 27 miles N. of Como.

SORIN, a river of France, which runs into the Rhone, at Roanne.

SORITES, Σωρειτης, formed from σωρος, *cumulus*, *heap*, in *Rhetoric*, &c. a kind of argument, in which ſeveral middle terms are choſen to connect one another ſucceſſively in ſeveral propoſitions, till the laſt propoſition connects its predicate with the firſt ſubject. Whence Cicero calls it *ſyllogiſmus acervatus*, an *accumulative ſyllogiſm*.

Such was that merry argument of Themiſtocles, to prove, that his little ſon, under ten years old, governed the whole world. Thus: "My ſon governs his mother; his mother me; I the Athenians; the Athenians the Greeks; Greece commands Europe; Europe the whole world: therefore my ſon commands the whole world."

This method of diſputing prevailed much among the Stoics; eſpecially with Zeno and Chryſippus; but it is very ſophiſtical.

SORITO, in *Geography*, a town of Naples, in Calabria Ultra; 5 miles E.S.E. of Mileto.

SORIVA, a town of Italy, in the Feltrin; 6 miles W. of Feltri.

SORKEY, a town of Hindooſtan, in Bahar; 15 miles W. of Rotaſgur.

SORLECHEU, a town of France, in the department of the Jemappe; 6 miles E.N.E. of Aveſnes.

SORNAC, a town of France, in the department of the Correze, and chief place of a canton, in the diſtrict of Uſſel. The place contains 1453, and the canton 5647 inhabitants, on a territory of 205 kiliometres, in 8 communes.

SORNI, a name given by ſome of the chemical writers to iron.

SORNZIG, in *Geography*, a town of Saxony, in the circle of Leipſic; 3 miles S. of Mugeln.

SORO, a river of Portugal, which runs into the Tagus, near Salvaterra, in the province of Eſtremadura.

SOROCEPHALUS, in *Botany*, ſo named by Mr. Brown, from σωρος, *a heap*, and κεφαλη, *the head*, alluding to the aggregate, or crowded, heads of flowers.—Brown Tr. of Linn. Soc. v. 10. 139. Ait. Hort. Kew. v. 1. 202.—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*, Juſſ. Brown.

Eſſ. Ch. Corolla four-cleft, regular. Stamens in the concave tips of the ſegments. Nectary four ſcales beneath the germen. Stigma vertical. Nut ſuperior. Involucrum of from three to ſix leaves, permanent, containing one, or a very few, flowers. Common receptacle naked.

Shrubs, with wand-like branches. Leaves ſcattered; either thread-ſhaped or flat, undivided; the lowermoſt only being occaſionally bipinnatifid. Involucrums nearly ſeſſile, with a ſolitary bractea, collected into a capitate terminal ſpike, ſometimes ſubtended by imbricated bracteas. Flowers purpliſh. *Brown.*

Mr. Brown deſcribes eight ſpecies, all natives of ſouthern Africa. Two are in the Engliſh gardens.

Section 1. *Spike nearly naked. Involucrum from one to three-flowered. Nut entire at the baſe, on a very ſhort ſtalk. Leaves thread-ſhaped, undivided.*

1. S. *ſetaceus*. Briſtle-leaved Sorocephalus. Br. n. 1.—"Involucrum ſingle-flowered. Leaves ſetaceous, incurved, hairy, as well as the branches."—Gathered by Dr. Roxburgh, at the Cape of Good Hope. An erect *ſhrub*, with ſtraight umbellate *branches*. *Leaves* numerous, an inch, or rather more, in length, with a briſtly faded point; the lower ones leſs incurved. *Head* terminal, ſeſſile, ovate, the ſize of a black cherry. Lower part of the *corolla* looſely downy; its ſegments bearded. *Stigma* ovate, ſomewhat conical.

2. S. *ſalſoloides*. Salt-wort Sorocephalus. Br. n. 2.—"Involucrum ſingle-flowered. Leaves triangular-thread-ſhaped, incurved, ſmooth."—From the ſame country. *Roxburgh*. Erect, very much branched. Youngeſt *branches* finely downy. *Leaves* half an inch long, furrowed above, with an acute point, nearly of their own colour. *Head* rather ſmaller than the former, accompanied underneath by a few minute lanceolate *bracteas*. *Corolla* bearded with ſhort hairs. *Stigma* erect, or ſlightly inclined.

3. S. *imberbis*. Beardleſs Sorocephalus. Br. n. 3.—"Involucrum three-flowered. Segments of the corolla, as well as the points of the bracteas, ſmooth."—Gathered by Mr. Niven, near the Cape of Good Hope. Much branched; the young *branches* downy. *Leaves* ſmooth, an inch long, moderately ſpreading, ſcarcely incurved, ſharp-pointed; furrowed above. *Head* on a ſhort ſtalk, terminal, nearly globoſe, the ſize of the firſt ſpecies. *Bracteas* lanceolate, fringed, with a ſmooth awl-ſhaped point. Lower part of the *corolla* bearded. *Style* ſtraight. *Stigma* club-ſhaped, equal.

4. S. *ſpatalloides*. Curve-ſtyled Sorocephalus. Br. n. 4.—"Involucrum three-flowered, ſomewhat ſtalked. Segments of the corolla bearded."—Found by Mr. Niven, near Franche-hoek, at the Cape of Good Hope. An upright *ſhrub*, with umbellate, finely downy, *branches*. *Leaves* ſcarcely an inch long, moderately ſpreading; hairy when young. *Heads* either ſolitary, or two or three together, ovate or oblong, the ſize of a hazel-nut, on ſhort ſtalks. *Bracteas* lanceolate, acute, downy; ſometimes ſmoothiſh at the point. *Corolla* bearded with long hairs. *Style* generally incurved at the point, in which caſe the *ſtigma* is ſomewhat unequal; but if the *ſtyle* be nearly ſtraight, it is ovate and equilateral.

Section 2. *Spike with more or leſs of a general involucrum. Partial involucrum with from four to ſix flowers. Nut emarginate at the baſe.*

5. S. *tenuifolius*. Slender-leaved Sorocephalus. Br. n. 5.—"Leaves thread-ſhaped, very ſhort. Heads of few flowers. Corolla with a feathery beard; its innermoſt ſegment nearly naked."—Gathered by Mr. Niven, in moiſt ſituations near Breed river, at the Cape of Good Hope. A *ſhrub* three or four feet high, with ſmooth, reddiſh, leafy *branches*; ſomewhat villous when young. *Leaves* imbricated, roughiſh, ſharp-pointed, not half an inch long; the younger ones hairy. Aggregate *head* terminal, ſeſſile, the ſize of a pea, compoſed of from two to four partial *heads*. Partial *involucrums* ſomewhat imbricated; their leaflets lanceolate, bearded, ſmoothiſh at the points. *Corolla* very deeply four-cleft, equal. *Style* ſtraight. *Stigma* ovate, erect, equilateral.

6. S. *lanatus*. Woolly Sorocephalus. Br. n. 6. Ait. n. 1. (Protea lanata; Thunb. Diſſ. n. 30. t. 3. Willd. Sp. Pl. v. 1. 519.)—Leaves triangular-thread-ſhaped; furrowed above. Heads of many flowers. All the ſegments of the corolla with feathery beards.—Native of Swartland, and other mountainous tracts, about the Cape of Good Hope. Sent to Kew garden, by Mr. Maſſon, in 1790. It flowers from June to September. An upright *ſhrub*, with ſomewhat umbellate, ſtraight, leafy, minutely downy *branches*. *Leaves* imbricated, from five to eight lines long. *Head* the ſize of a large hazel-nut, ſeſſile, globoſe, ſolitary; the partial ones very cloſely crowded, each of from five to eight

flowers. *Involucrums* of from five to ſeven narrow-lanceolate bearded leaves. *Corolla* equal, deeply divided. *Style* ſtraight, with a thick equilateral *ſtigma*. *Nut* finely downy, with a thin, brown, ſlightly rugged, ſhell; its ſtalk very ſhort. The *leaves* are occaſionally roughiſh or ſmooth, their keel rounded or acute.

7. S. *imbricatus*. Imbricated Sorocephalus. Br. n. 7. Ait. n. 2. (Protea imbricata; Thunb. Diſſ. n. 45. t. 5. Linn. Suppl. 116. Willd. Sp. Pl. v. 1. 527. Andr. Repoſ. t. 517.—Leaves lanceolate; rough underneath. Baſe of the corolla clothed with glandular hairs. *Stigma* club-ſhaped.—Found on hills at the Cape of Good Hope. Sent to Kew, by Mr. Maſſon, in 1794. Mr. Hibbert alſo obtained it from his collector there, Mr. Niven. This has the habit of the foregoing, but the *leaves* are lanceolate, near an inch long; hairy beneath, and at the edges; ſmooth above. *Head* ſeſſile, ovate or oblong, either ſolitary, or compoſed of two or three crowded together; with a common *involucrum*, of many lanceolate coloured leaves. Each partial *involucrum*, of four lanceolate hairy leaves, uſually contains four flowers. *Corolla* ſlender, purpliſh; its ſegments bearded, with a long denſe tuft of white hairs, as is likewiſe the *germen*. *Style* ſtraight. *Stigma* a little gibbous. *Nut* oblong, brown, very ſmooth and ſhining.

8. S. *diverſifolius*. Various-leaved Sorocephalus. Br. n. 8.—"Leaves ſpatulato-lanceolate; ſmooth underneath: the lowermoſt doubly pinnatifid. Corolla bearded throughout. Stigma cylindrical."—Gathered by Mr. Niven, on ſtony hills near *Goud Rivier*, at the Cape of Good Hope. A ſmooth *ſhrub*, whoſe *ſtem* is from two to ſix feet high, either ſimple or divided, ſtraight, erect, as thick as a ſwan's quill; downy in the upper part. *Lower leaves* two inches long, twice three-cleft, channelled; the reſt imbricated, bluntiſh, ſcarcely concave, hardly half an inch in length. *Head* ſeſſile, ſolitary, ovate, obtuſe, the ſize of a ſmall plum.

SOROCHINSKAIA, in *Geography*, a fortreſs of Ruſſia, in the government of Upha, on the Samara; 80 miles N.W. of Orenburg.

SOROE, a town of Denmark, in the iſland of Zealand, ſurrounded by three freſh-water lakes. In this place is a royal academy, endowed with the revenues of a rich convent, which was diſſolved at the revolution; 35 miles S.W. of Copenhagen. N. lat. 55° 27′. E. long. 11° 30′.—Alſo, a ſmall iſland in the North ſea, near the coaſt of Norway. N. lat. 70° 30′.

SOROOMAN, a town of Arabia, in the province of Oman; 110 miles S.W. of Julfa.

SOROTO, a town of Thibet; 70 miles W.N.W. of Cha-tcheou.

SORRANCES, among *Farriers*, ſignify two things; *viz.* either an ill ſtate, or habit, of a horſe's body, ariſing from ſome part diſeaſed; or a looſening and ſolution of the continuity of the parts; which, according to the various circumſtances of it, acquire new names, as fracture, wound, ulcer, rupture, convulſion, cramp, excoriation, &c.

Sorrance-*Water*, a name given by our farriers to a ſolution of vitriol, and ſome other ingredients, in vinegar; a medicine much eſteemed in many of the diſeaſes of horſes. It is prepared in the following manner.

Take Roman vitriol, and roach-alum, of each an ounce and a half; verdigris, an ounce; copperas, two ounces: reduce all theſe to powder together, and put them into a two-quart bottle, into which pour a quart of the ſtrongeſt and beſt wine-vinegar; this is to be ſet in balneo Mariæ. The ſhort way of doing which by the farrier, is this: he puts a wiſp of hay into the bottom of the kettle, and then tying ſome pieces of lead or iron about the neck of the bottle, to make it heavy enough to ſink in water, it is ſet upon the hay ſo, as to ſtand very upright; then three notches are cut lengthwiſe in the cork to give paſſage to ſome of the vapours when the bottle is heated, that it may not burſt. When every thing is thus prepared, ſo much cold water is to be put into the kettle, that the neck of the bottle may ſtand two or three inches above it; the kettle is then to be ſet over the fire, and the water is to be made to boil, and kept boiling about half an hour, the bottle being at times taken out, and thoroughly ſhaken. When the ſalts are thus thoroughly diſſolved in the vinegar, the whole is to be kept for uſe.

The method in which they uſe it is this: take an earthen pan, which will hold about twelve quarts; let this be filled with urine that has been made by ſound, healthy, and young perſons; the ſtaler the urine is, the better it is for uſe, and it ought indeed always to ſtand, at leaſt, three weeks before it is uſed. It is proper for the farrier, therefore, always to keep a quantity of this ready, and when the water is to be uſed, half a pint of it is to be mixed with a quart of the urine; or, if it be required ſtronger, more of the water is to be added: theſe are to be thorougly mixed together, and the legs, or other affected part of the horſe, bathed with it with ſoft rags twice a-day.

The virtues of this water are highly extolled: it is ſaid to cure the malanders in two or three times dreſſing; it is alſo a ſovereign remedy for the mange, either dry or wet, and for the rat-tails, ſcratches, gourded or ſwelled legs and heels, and it alſo cures horſes when the greaſe is fallen into their heels, as the farriers expreſs it. The farcy is alſo ſaid to be often cured by a long continuance in the uſe of it, purging the horſe two or three times, at different diſtances of time, during the time of his being under cure by the water. They alſo find it a good cleanſer and healer of foul ulcers, and that it prevents the breeding of proud-fleſh and worms in wounds, and drives away a flux of humours that were falling upon any part. They uſe it alſo in clefts and cracks of the heels, and in windgalls, eſpecially in the prevention of the laſt, by its repellent qualities. The green water alone is an excellent remedy for fiſtulas, cankers, and the galled backs of horſes; diſpoſing ſuch ſorrances, as they are called, not to feſter, rot, and grow worſe, as all greaſy and oily medicines do, but cleanſing them, and preparing the way to a very ſound and ſtanding cure.

SORREL, Acetosa, in *Botany*, *Gardening*, and the *Materia Medica*. See Rumex.

Sorrels, *Indian Red*, and *Indian White*, or *Syrian Mallow*, in *Botany*, are ſpecies of *Hibiſcus*; which ſee.

Sorrel, *Wood*, in *Botany*, *Gardening*, and the *Materia Medica*. See Oxalis.

Sorrel, *Common* and *Curled*, in *Agriculture*, troubleſome weeds in meadows and paſture lands; alſo the latter in cultivated arable ground, where neither horſes nor neat cattle will eat it, which, of courſe, renders it neceſſary to be eradicated. This is moſtly accompliſhed by rooting it out, or frequently cutting the ſtalks over juſt below the ſurface of the land. It has often the title of curled dock. See Weeds.

Sorrel, in the *Manege*, is uſed for a reddiſh colour. The mane ought to be red or white, in a horſe of this colour. It is diſtinguiſhed, according to the degrees of its deepneſs, into a *burnt* ſorrel, and a *bright* or *light* ſorrel. Generally ſpeaking, it is a ſign of a good horſe.

Sorrel, *Salt of*, in *Chemiſtry*, the native ſuper-oxalat of potaſh, contained in the juice of this plant. See OXALIC *Acid*.

SORREL-*Tree*, in *Botany*. See ANDROMEDA.

SORRO, in *Geography*, a town of Africa, in Beeroo; 85 miles S.W. of Walet.

SORROINSU, a town of the department of Liamone, or iſland of Corſica; the canton of which contains 1528 inhabitants.

SORS, a town of the iſland of Sardinia; 10 miles N.N.E. of Saſſari.

SORSELE, a town of Swediſh Lapland, in the lapmark of Pitea; 105 miles W. of Pitea. N. lat. 65° 33°. E. long. 17° 20′.

SORSOKEN, a ſea-port town in the S.E. part of the iſland of Luçon.

SORT, a town of Spain, in the province of Catalonia; 18 miles W. of Urgel.—Alſo, a ſea-port town of Africa, in the country of Tripoli, ſituated on the coaſt of the Mediterranean, in the gulf of Sidra. N. lat. 30° 28′. E. long. 16° 55′.

SORTES, LOTS, in *Antiquity*, a method of deciding dubious caſes, where there appears no ground for a preference; by referring the deciſion to chance; as in caſting of dice, drawing of tickets, &c.

The ſortes, or lots, were of ancient uſe among the Jews; and in the books of the Old Teſtament we meet with divers ſtanding and perpetual laws, and divers particular commands, preſcribing and regulating the uſe of them. Thus, the Scripture informs us, that the lot fell on St. Matthias, when a ſucceſſor to Judas in the apoſtolate was to be choſen. Our Saviour's garment itſelf was caſt lots for.

The SORTES *Præneſtinæ* were famous among the Greeks. The method of theſe was to put a great number of letters, or even whole words, into an urn; to ſhake them together, and throw them out; and whatever ſhould chance to be made out in the arrangement of the letters, &c. compoſed the anſwer of this oracle.

Cicero, de Divin. lib. ii. § 41, ſays, that a variety of predictions were inſcribed on pieces of wood, which were kept in a box or cheſt; and one of theſe drawn out by a child, after the box was ſhaken, contained the anſwer ſought. He alſo informs us, how theſe fragments of wood were firſt diſcovered; but he obſerves, "Tota res eſt inventa fallaciis, aut ad quæſtum, aut ad ſuperſtitionem." In lieu of this, another kind of ſortes was introduced into Greece and Italy; which was, to take ſome celebrated poet, as Homer, Euripides, or Virgil, to open the book, and whatever firſt preſented itſelf to the eye upon opening, was taken for the ordinance of heaven. This made what they called the *ſortes Homericæ*, and *ſortes Virgilianæ;* which ſucceeded to the uſe of the *ſortes Præneſtinæ*.

The bath *kol* among the Jews was much of the ſame kind, differing only in this circumſtance, that the Jews took their oracle from the firſt words which they heard any body pronounce; the Heathen, from the firſt they caſt their eyes upon, on opening Homer, &c. in which they endeavoured to diſcover a meaning ſuitable to the matter concerning which they inquired.

This ſuperſtition paſſed from Paganiſm into Chriſtianity; and the Chriſtians took their ſortes out of the books of the Old and New Teſtament. The firſt paſſage that preſented itſelf upon opening a book of Scripture, was eſteemed the anſwer of God himſelf.

If the firſt paſſage did not happen to be any thing to the purpoſe for which the ſortes were conſulted, another book was opened; till a paſſage was met with that might be taken for an anſwer. This was called *ſortes ſanctorum*. St. Auguſtine (Epiſt. ad. Jan. 109.) does not diſapprove of this method of learning futurity, provided it be not uſed for worldly purpoſes.

Gregory of Tours adds, that the cuſtom was firſt to lay the Bible on the altar, and to pray the Lord, that he would diſcover by it what was to come to paſs. Inſtances of the uſe of the ſortes ſanctorum are very frequent in hiſtory. Heraclius, M. Fleury tells us, in his war againſt Choſroes, to learn where he ſhould take up his winter-quarters, purified his army for three days, and then opened the Goſpels, and found the place appointed for his winter-quarters was in Albania.

Gilbert of Nogent informs us, that, in his time, (that is, about the beginning of the 12th century,) the cuſtom was, at the conſecration of biſhops, to conſult the ſortes ſanctorum, to learn the ſucceſs, fate, &c. of their epiſcopate.

The practice is founded on a ſuppoſition, that God preſides over the ſortes, and on Prov. xvi. 33. "The lot is caſt into the lap; but the diſpoſing thereof is of the Lord."

In effect, many divines hold that the lot is conducted in a particular manner by Providence; that it is an extraordinary manner in which God declares his will by a kind of immediate revelation. The ſortes ſanctorum, however, were condemned by the council of Agda, in 506, at the time they were beginning to take footing in France, &c.

SORTILEGE, SORTILEGIUM, a kind of divination by ſortes, or lots.

SORTING *Sheep-Stock*, in *Agriculture*, the practice of carefully chooſing, ſorting, collecting, and putting together, thoſe which are the moſt proper and beſt ſuited for the purpoſe of breeding, or any other uſe that may be in the contemplation of the grazing farmer. It is a practice which has hitherto, for the moſt part, only prevailed among the larger and better kinds of ſheep-farmers, but which ought to be every where attended to where good ſheep-ſtock is wanted, and good management with them to be purſued. It, however, requires great care and attention in the execution, in order to perform it in a proper manner; but, when well conducted, amply repays the judgment and ſkill of the ſtock-farmer. The proper introduction of new and approved breeds has done much in bettering this ſort of ſtock, by promoting a more ſpirited attention to the ſubject, and inculcating the neceſſity of a more careful ſelection; as, ſince this has been the caſe, very evident improvements have taken place in the forms and diſpoſitions of ſheep, as well as in the quality of their wool.

The utmoſt care and attention are conſtantly demanded in the ſelection of ſuch ſheep as are to be bred from; and as it would require a great length of time to correct and remove the errors and bad conſequences that might ariſe from any neglect in ſo important and eſſential a matter, the ſheep-maſter ſhould always himſelf be, as much as poſſible, employed in the buſineſs. He ſhould take care that the ewe tegs, or young ewes, be very fully and ſtrictly examined in the mouths, to ſee that they are not chopped or defective in ſuch parts; their make ſhould be ſeen to be proper and handſome in all points, and their wool of a ſuperior quality; the ſtaple being well ſuited to the paſture or nature of the keep, rather ſhort than long, as ſhort wool is commonly thick, and kindly for the ſheep; but when too long, it is apt to be thin, and to draw too much nouriſhment from the animal, without affording the neceſſary warmth and protection in the winter ſeaſon. Theſe ſorts of ſheep ſhould in all caſes be ſorted down, or refuſed, as it is called, in a very cloſe manner; and when there are not more than are wanting to put the ram to, and many of theſe are defective, all ſuch ſhould be fattened or ſold, and their places ſupplied by the beſt of the old ewe-ſtock, which would otherwiſe be ſent away. This is not generally practiſed, but it is evident that a well-formed or perfect old ewe muſt be better for breeding from, than ſuch young ones as are ill-formed or imperfect in their ſhape.

There are different periods for the ſorting or ſelecting of ſheep-ſtock; as the time when the ewes are arranged and put into different claſſes for the rams, the ſeaſon of lambing, &c.: in each of which, the defects and imperfections of them may be diſcovered without much difficulty. But the moſt proper time of all, according to ſome, is in the early ſpring, as about the beginning of March, as then the ſoft, the long, the coarſe wool, and all other imperfections in the ewes, are the moſt conſpicuous, and readily detected, and thoſe of the beſt forms, qualities, and diſpoſitions, may be the moſt fitly drawn off and preſerved; as ſuch ſheep as are capable of ſupporting themſelves, and of looking well under the difficulties of a ſevere winter ſeaſon, muſt in general be the moſt deſerving of the breeding ſheep-farmer's attention; while ſuch as have wintered badly will not unfrequently ſhew a good diſpoſition in the ſummer ſeaſon. In theſe caſes, where imperfections are diſcovered, the ſheep ſhould either be drawn off, put out, and lambed by themſelves, or a private mark ſet upon them; and the ewes and lambs ſold or made fat. Thus, the number of bad ill-formed ſheep, that ought not to be kept, are conveniently reduced and completely got rid of, which, if they or their lambs were ſuffered to blend and intermix with the well-formed ſheep, the ſtock would be in danger of being contaminated. It is the common practice in moſt caſes, to only ſelect or ſort the ſheep once in the year; but with good managers they are had under hand two or three times in the ſame ſpace of time; and whenever a ſheep is ſeen with any ſort of defect, it is immediately marked, and ſent to be made fat.

Many make this ſorting, or inſpection, ſo late as the beginning of the autumn, but an earlier performance of the buſineſs is evidently preferable, in order that the defective ſtock may be put to fatten in proper time.

The manner of performing the buſineſs is commonly by pounding the ſheep in a ſmall number at a time, ſo that the ſheep-farmer may be able to examine them at once, without the danger of being diſtracted or confuſed by having too many expoſed to his view, and conſequently be incapable of diſtinguiſhing the properties of their forms, and other qualities which ought to be particularly attended to in forming his deciſion. In the execution of this work, the farmer, his ſhepherd, or looker, are provided with ochre, or ſome other material, for giving the defective ſheep the uſual private mark, in order that they may be known from the perfect part of the flock, and be diſpoſed of accordingly. This marking, or *tivering*, as it is called in ſome places, is performed differently, according to circumſtances, as the purpoſes the ſheep are to be put to, and the number of lambs the ewes have had. It is well done ſometimes alſo to have the ſheep marked with pitch, according to their ages. See TIVERING.

The defects which are chiefly to be taken notice of in the ſorting of ſheep in this intention, are thoſe of bad ſhape, as the head being thick or too long, the body too long and narrow, without ſufficient roundneſs, the feet and bones too large, the cheſt too much confined, the want of ſtraightneſs in the back, too great a length in the legs and neck, the ſheep being too large for the paſture or keep, their not handling in a proper manner, the wool bad, as too coarſe or too long and picky, or coming off, waxy, or hempy, the ſheep being louſy, ſtruck with the fly, gally, thick pelted, and ſcurvy, their being hog-chopped, that is, having the lower jaw ſhorter than the upper one, by which their feeding properly is prevented, the mouths large, cauſing the loſs of the cud in rechewing their food, &c. By ſorting and ſelecting ſheep as free as poſſible from defects of theſe kinds, the beſt ſheep-ſtock may be procured, provided the true form be properly underſtood and conſtantly kept in mind, without ſuffering it to be injured in any way by the admiſſion of improper qualities at any time, or under any circumſtances.

The ſorting or ſelection of ſheep in this intention, may perhaps be a little different in different caſes; but wherever a good ſtock is aimed at, the breeding ſheep-farmer ſhould of courſe ſelect that breed, whatever it may be, which is moſt ſuited to his circumſtances and purpoſes, and which the moſt nearly approaches towards the ſtate of perfection in its form and other properties, or which poſſeſſes that particular kind of improvement which he is in want of, being conſtantly well aware what conſtitutes ſuch ſtates in the animal. The parts of his ſtock which are deficient, or do not fully come up to or poſſeſs ſuch properties, are always to be ſorted out and rejected, being ſold or turned off for the purpoſe of fattening, both in the ewes and the lambs, as they might be in danger of accidentally injuring the ſtock. Good breeding ſheep-farmers are alſo at all times cloſely on the watch to have none but thoſe of ſuperior qualities, and to take advantage of any accidental improved variety which may anſwer their intentions. The full proper culling or ſelecting and ſorting of the younger part of the ewe-ſtock, is in all caſes a material point in having good ſheep-ſtock, and one which is never to be neglected. The careful breeder ſhould indeed continually have his eyes upon his flock, to ſee that there are no faulty animals continued in it, eſpecially in any material degree, as much may be effected in this way, and the trouble of ſorting be conſiderably leſſened. See BREEDING, LIVE-STOCK, and SHEEP.

The practice of ſorting ſheep is not, however, uſeful only for the purpoſe of breeding, but may be beneficially employed in other intentions. The ſorting of ſheep, according to their ages, ſizes, kinds, and other qualities, is often highly important and advantageous in the ſtocking of paſture lands, as it enables the ſheep-farmer to do it with greater propriety and correctneſs, as well as with a greater profit in the improvement of the ſtock. See STOCKING *Paſture Land.*

Sheep are likewiſe ſorted with very much benefit for the different purpoſes of ſtore-feeding, lambing, fattening, and other ſorts of management with them.

But however beneficial the practice may be in theſe ſeveral intentions, as well as in ſome others, it is probable that it has hitherto been attempted only in a few inſtances, and in many of thoſe in much too ſlight and inattentive a manner; it is, notwithſtanding, of the utmoſt neceſſity and importance in the management of this ſort of live-ſtock, and when once well underſtood and properly performed, cannot fail of producing very advantageous effects, and much improvement in the buſineſs of ſheep-farming.

SORTINSKOI, in *Geography*, a town of Ruſſia, in the government of Tobolſk; 72 miles S.S.W. of Berezov.

SORTOWITZ, a town of Pruſſia, in the palatinate of Culm; 10 miles N. of Culm.

SORVIODUNUM, or SORBIODUNUM, in *Ancient Geography*, a town of the iſle of Albion, upon the route from Calleva to Vrioconium, in paſſing by Muridunum between Brige and Vindocladia, according to the Itinerary of Antonine; Calleva being Silcheſter, Muridunum, being Eggerton, Vrioconium being Wroxeter, Brige being Broughton, Vindocladia near Cranburn, and Sorbiodunum being Old Sarum.

SORUNDO, in *Geography*, a town of Sweden, in Sudermanland; 20 miles S.S.W. of Stockholm.

SORUS, in *Botany* and *Vegetable Phyſiology*, from σωρος, *a heap*, is a term recently introduced, for the aſſemblage of capſules in Ferns, which had hitherto been called a dot, ſpot, or line, according to its particular figure. (See FILICES.) The *Sori* in many kinds of *Polypodium* and *Aſpidium* are very much elevated, or prominent, well anſwering to this appellation, which is indeed, in every caſe, more correct and leſs exceptionable than the terms it ſuperſedes. In an early ſtate, the *Sori* are little more than ſpots, more or leſs opaque, or quite pellucid, in whoſe homogeneous ſubſtance nothing can be diſcerned of the myſtery of impregnation, though certainly performed there. Whether that myſtery takes place before the ſhape of each particular capſule is developed, we cannot determine, though it appears moſt probable; for if the *Sori* ſwell at all, they do not ſeem to fail afterwards. If they do not come to perfection, they remain in their original ſtate, of a ſcarcely conſpicuous dot.

SORUT, in *Geography*, a circar of Hindooſtan, in Guzerat; 120 miles long, and 40 broad.

SORWY, a river of Monmouthſhire, which runs into the Edwith.

SORY, in *Natural Hiſtory*, the name of a foſſile ſubſtance, much ſpoken of by the ancients, but erroneouſly ſuppoſed to be now loſt.

It is a firm and not brittle ſubſtance, though of a ſpongy and cavernous ſtructure, and is conſiderably heavy. It is found in maſſes of no regular ſhape or ſize, ſome being roundiſh, others angular or flatted, and ſome of the ſize of a walnut, others of many pounds weight. It feels very harſh and rough to the touch, and is covered with no inveſtient coat or cruſt, but ſhews its natural ſurface, which is always corrugated or wrinkled, and uſually full of ſmall protuberances and cavities, and when broken, is found to be of a rugged and ſpongy ſtructure within.

Its natural colour is a ruſty black, but it is ſometimes reddiſh, and ſometimes blueiſh: and is commonly ſtained, in different places, with ſpots of a blueiſh or ruſt colour, when black; and of a greeniſh hue, when it is of a reddiſh colour: in the places where it is free from theſe, it is uſually ſomewhat bright and ſparkling. It is of an acrid and diſagreeable taſte, and of a ſtrong and nauſeous ſmell; put into the fire it burns to a deep purple; and if boiled in water a great part of it becomes diſſolved in it; and this may again be ſeparated from the water by evaporation and cryſtallization, and then appears in the form of pure blue vitriol, forming regular rhomboidal cryſtals, and tinging iron to a copper colour, on being firſt wetted, and then rubbed upon it.

It is found in many parts of the Turkiſh dominions, particularly in Gallo-Græcia; as alſo in ſome parts of Germany. In this country it is boiled for the blue vitriol it contains. In Turkey it is mixed with lime, and made into a paſte with water, which is laid on ſuch parts of the body as they would eradicate the hair from, and effects that purpoſe in a very few minutes. In the eaſtern nations, where it is thus uſed, it is known by the name of ruſma.

The ancients uſed it externally to take off pimples, and put a piece of it into a hollow tooth, as a remedy for the tooth-ache. There can be no doubt of their ſory being the ſame ſubſtance with this; ſince Dioſcorides has deſcribed it to be blackiſh in colour, full of ſmall cavities, moiſt on the ſurface, (as ours always is in moiſt weather,) and of a diſagreeable taſte and ſmell.

This ſubſtance, as alſo the chalcitis, miſy, and melanteria, are all properly ores of vitriol, the particles of thoſe ſalts being ſo perfectly blended in them, as not to be at all diſtinguiſhable to the naked eye, yet being always regularly ſeparable from them by water, which is to the ſaline ores what fire is to thoſe of the metalline kind. Hill's Hiſt. of Foſſ. p. 606.

SORYGAZA, in *Ancient Geography*, a town of India, on the banks and on the other ſide of the Ganges, towards the eaſtern coaſt. Ptolemy.

SOS, in *Geography*, a town of France, in the department of the Lot and Garonne; 10 miles S.W. of Nerac.—Alſo, a town of Spain, in Aragon; 30 miles W. of Jaca.—Alſo, a river of Spain, in Aragon, which runs into the Sinca, near Monçon.

SOSA, a town of Saxony, in the circle of Erzgebirg; 22 miles S.S.W. of Chemnitz.

SOSE, a river of Germany, which runs into the Ruhme, 9 miles E. of Nordheim.

SOSES, a town of Spain, in Catalonia; 6 miles S.W. of Lerida.

SOSIBES, in *Ancient Geography*, a people who inhabited the environs of Aſiatic Sarmatia, and who are comprehended, by Julius Capitolinus, in the number of thoſe who had conſpired againſt the Roman empire, under Marcus Antoninus the philoſopher.

SOSIGENES, in *Biography*, a Peripatetic philoſopher, and ſkilful aſtronomer, was brought from Egypt by Julius Cæſar, with the view expreſsly of aſſiſting him in reforming the calendar. The philoſopher, by tolerably accurate obſervations, diſcovered that the year was 365 days and 6 hours; and to make allowance for the odd hours, he invented the intercalation of one day in four years; and the duplication of the ſixth day before the calends of March was the intercalary day: and hence the year in which this took place was called Biſſextile. This was called the Julian year, the reckoning by which commenced in the 45th year B.C., and continued till it gave place to ſomething more accurate, and a ſtill farther reformation under pope Gregory XIII. Soſigenes was author of a commentary upon Ariſtotle's book "De Cœlo."

SOSIPPUS PORTUS, in *Ancient Geography*, a port of Arabia Felix, on the coaſt of the Arabian gulf, between Muſa Emporium and Pſeudocelis, according to Ptolemy.

SOSNINSKAIA, in *Geography*, a town of Ruſſia, in the province of Novgorod; 32 miles N. of Novgorod.

SOSNITZA, a town of Ruſſia, in the government of Novgorod Sieverſkoi; 32 miles S.S.W. of Novgorod Sieverſkoi. N. lat. 51° 30′. E. long. 32° 46′.

SOSNOPA, a town of Ruſſia, in the government of Perm; 48 miles S. of Oſa.

SOSNOVOI, an iſland of Ruſſia, in the river Angara; 96 miles N.N.W. of Ilimſk.

SOSNOVSKOI, a town of Ruſſia, in the government of Kolivan. N. lat. 55° 50′. E. long. 85° 44′.

SOSPELLO, a town of France, in the department of the Maritime Alps, and chief place of a canton, in the diſtrict of Monaco; divided by a ſmall river into two parts. The town contains 2990, and the canton 5512 inhabitants, on a territory of 142½ kiliometres, in 4 communes. It is the ſee of a biſhop, united with Vintimiglia; containing four churches, one of which is a cathedral, and two convents; 10 miles N.E. of Nice.

SOSPIRO, Ital., *Soupir*, Fr., a crotchet reſt in *Muſic*. See CHARACTERS and TIME-TABLE.

Sospiro, *Al Canone*. See Canone *al Soſpiro*.

SOSSINATI, in *Ancient Geography*, a name given to one of the four claſſes of mountaineers in the iſle of Sardinia, who took up their abode in caverns. Strabo.

SOSSIUS, a river on the ſouthern coaſt of Sicily, between the town Pintia and the mouth of the river Iſbarus. Ptolemy.

SOSTENUTO, in *Italian Muſic*, *Soutenu*, Fr., ſuſtained, continuing ſounds and uniting them to each other, in oppoſition to *ſpiccato*, detached. See Legato.

SOSTI, in *Geography*, a town of Naples, in Calabria Ultra; 10 miles S. of Squillace.

SOSTRATUS, in *Biography*, the moſt eminent architect of his time, was a native of Gnidos, in Leſſer Aſia, and flouriſhed in the third century before the Chriſtian era. The patronage which he met with, cauſed him to be denominated the friend of kings; and he was particularly in favour with Ptolemy Philadelphus, ſovereign of Egypt. He is celebrated in hiſtory likewiſe for the *terraces*, ſupported on arcades, which adorned his native city; and the famous *Pharos*, the light-houſe of Alexandria, which was reckoned one of the wonders of the world. He tranſmitted his name to poſterity by an inſcription on this light-houſe, in the Greek language, of which the tranſlation is, "Soſtratus of Gnidos, the ſon of Dexiphanes, dedicates this to the gods, the protectors of navigators."

SOSVA, in *Geography*, a river of Ruſſia, which riſes in the government of Tobolſk, N. lat. 61° 10′. E. long. 59° 54′, ſoon after enters into the province of Ekaterinburg, and takes a ſouthern courſe to lat. 59°, then bends its courſe eaſterly, and loſes itſelf in lake Phelim, in the government of Tobolſk, N. lat. 59° 15′. E. long. 63° 54′.—Alſo, a river of Ruſſia, which runs into the Oby, 40 miles S. of Berezov.

SOSZNIZOWITZ, or Saszinkowitz, a town of Sileſia, in the principality of Oppeln; 35 miles S.E. of Oppeln. N. lat. 50° 14′. E. long. 18° 28′.

SOTA DE PALANA, a town of the iſland of Cuba; 100 miles S.W. of Havanna.

SOTCHEOU, a town of Corea; 403 miles E. of Peking. N. lat. 40° 9′. E. long. 124° 34′.

SOTELLO, a town of Spain, in Old Caſtile; 30 miles S. of Burgos.

SOTER, in *Biography*, pope, a native of Fondi, in the Campagna of Rome, was elected to the Roman ſee on the deceaſe of Anicetus, in the year 168. During the period that he ruled the church, the hereſy of the Montaniſts made its appearance, and he is ſaid to have compoſed a book againſt their doctrines; but as the title is not known, the fact itſelf is liable to much doubt. Four decretals have been aſcribed to him, but they are generally regarded as ſpurious. He died in 176, and he has been enrolled among the martyrs by modern writers, but no ancient one gives him that title. He is, however, generally commended for the contributions which he cauſed to be raiſed for the relief of the poor brethren in foreign countries, and particularly for thoſe who were condemned to the mines, on account of their faith.

SOTERIA, formed from σωτηρ, *ſaviour*, in *Antiquity*, ſacrifices offered to the gods, in gratitude for their having delivered a perſon from danger. See Sacrifice.

The term is alſo applied to poetical pieces compoſed for the ſame end. Orpheus is the firſt who appears to have compoſed ſoteria.

Our Latin poets give the ſame name to poems in Latin verſe, written to give thanks to God, or the ſaints, for having preſerved them on any occaſion. F. Petavius being delivered from a dangerous diſeaſe, by the interceſſion, as he ſuppoſed, of St. Genevieve, compoſed that fine piece in honour of that ſaint, ſtill extant under the title of "Soteria."

SOTERUS, in *Ancient Geography*, a port of the Arabian gulf, according to Diodorus Siculus.

SOTI, in *Geography*, a town of Africa, in the country of Whidah; 18 miles W. of Sabi.

SOTIRA, in *Ancient Geography*, a town of Aſia, in Aria. Ptol.—Alſo, a town of Aſia, in Cappadocia, Pliny.—Alſo, a town of Parthia. Arrian.

SOTIRELLA, a name given by ſome to a compound medicine, in form of a hard maſs, and conſiſting of opium, and ſome other narcotics, with camphor, wood-ſoot, and nutmeg. It is deſcribed in the Auguſtan Diſpenſatory, and is intended to be put into hollow teeth, as a remedy for the tooth-ache.

SOTO, Dominic, in *Biography*, a learned Spaniſh eccleſiaſtic, was born at Segovia in 1494. His father was a gardener, and his circumſtances being of a very humble nature, he deſtined his ſon for the ſame occupation; but having learned the elements of inſtruction, he officiated in the duties of ſacriſtan in a village church, and at length rendered himſelf qualified to ſtudy philoſophy at the univerſity of Alcala. He afterwards completed his ſtudies at Paris; and on returning to Spain, entered into the Dominican order. He was employed as a profeſſor in different univerſities, and publiſhed commentaries on the Ariſtotelian philoſophy. In 1545 he was deputed as a theologian to the council of Trent, and was one of the perſons to whom was committed the office of recording deciſions of the aſſembly, and drawing up its decrees. He was a frequent and able ſpeaker in the council, and maintained the propoſition, "that the reſidence of biſhops is of divine right." The emperor Charles V., in 1549, offered him the biſhopric of Segovia, which he refuſed. He was, however, perſuaded to take the office of judging between Las Caſas and Sepulveda, in their conteſt reſpecting the Indians, which he determined in favour of the former. He then retired to Salamanca, where he died in 1560. His chief works are, "De Juſticia et Jure;" "De Tegendis Secretis;" "De Pauperum Cauſa;" "De Cavendo Juramentorum Abuſu."

SOTOVENTO, in *Geography*, a name applied to the Leſſer Antilles in the Weſt Indies. Among theſe, the chief may be reckoned Trinidad, Margaretta, Curaſſoa, and Tortugas.

Sotovento *Lobos*, or *Leeward Iſland of Sea-Wolves or Seals*, an iſland on the coaſt of Peru; 7 leagues from Barlevento Lobos, or Windward iſland of ſea-wolves. It is about 6 miles in circuit, and 15 miles from Cape Aguja.

SOTTEGHEM, a town of France, in the department of the Scheldt, and chief place of a canton, in the diſtrict of Audenaerde. The place contains 1508, and the canton 14,603 inhabitants, on a territory of 77½ kiliometres, in 14 communes.

SOTTERN, a lake of Sweden, in the province of Nericia; 14 miles S.E. of Orebro.

SOTTEVAST, a town of France, in the department of the Channel; 9 miles W. of Valognes.

SOTTEVILLE, a town of France, on the ſouth ſide of the Seine; 3 miles S. of Rouen.

SOTTO Voce, in *Italian Muſic*, implies a degree of *piano*, or ſoft, and ſubdued voice; which is ſometimes expreſſed by *mezzo forte*, and *mezza voce*, half piano.

SOU, in *Commerce*. See Sol.

Sou, or *So-tcheou*, in *Geography*, a town of China, of the ſecond rank, in Chen-ſi. N. lat. 39° 38′. E. long. 98° 44′.

SOUADI, or Soually, a town of Egypt, on the eaſt ſide of the Nile; 23 miles S. of Abu Girgé. This burgh is governed by a cachef; and weſt of it are two Coptic monaſteries, ſituated at the entrance of the deſert. Their churches are ornamented with Corinthian pillars, with a croſs in the middle of the capital; and they are paved with red granite, covered with hieroglyphics. Their architecture is ſaid by Savary to indicate the decline of taſte among the Greeks. They are thought to have been built by the empreſs Helena. On the ſpace between them are ſtrewed antique marbles. Theſe remains point out the ſcite of Crocodilopolis, or the ſacred city of this name, which was far from the river, and which Ptolemy places after Aphroditopolis, or the city of Venus.

SOUADY, or Sohar, a ſmall iſland in the Arabian ſea, near the coaſt of Oman. N. lat. 24° 14′.

SOVANA, a town of Etruria, the ſee of a biſhop; 45 miles N.N.W. of Rome.

SOUANANPOUR, a town of Hindooſtan, in Golconda; 10 miles S. of Hydrabad.

SOVANOCALCHI, in *Ancient Geography*, a people of Aſiatic Sarmatia, upon the banks of the Euxine ſea. Ptolemy.

SOUBES, in *Geography*, a town of France, in the department of the Herault; 3 miles N. of Lodeve.

SOUBIZE, a town of France, in the department of the Lower Charente; 3 miles W. of Rochefort.

SOUC, a town of Thibet; 360 miles N.N.E. of Laſſa. N. lat. 33° 18′. E. long. 94° 24′.

SOUCTOU, a mountain of Thibet. N. lat. 32° 18′. E. long. 84° 19′.

SOUCY, a town of France, in the department of the Yonne; 19 miles S. of Provins.

SOUDAH, a rocky deſert country of Africa, between Tripoli and Fezzan.

SOUDAN, from *Souda* or *Suda*, which ſignifies in Arabic *black*, a name given by the Moors and Arabs to Negroland, or Nigritia; and ſometimes more particularly to the empire of Hauſſa, or Houſſa. Abulfeda includes the whole lower part of Africa, ſouth of the Great Deſert and Egypt, under the denomination of Belad Soudan, or the country of Soudan. With him Soudan is the ſouthern quarter of the globe; and d'Herbelot alſo allows it a wide range. See Negroland.

SOUDE ST. CROIX, a town of France, in the department of the Marne; 10 miles W. of Vitry.

SOVEIB, a town of the Arabian Irak, on the Euphrates; 20 miles N.W. of Baſſora.

SOUE-KI, a town of China, of the third rank, in Quang-tong; 30 miles S.W. of Hoa.

SOVEL, a ſmall iſland in the Chineſe ſea, near the coaſt of Tonquin. N. lat. 11° 2′. E. long. 105° 25′.

SOUE-OUIE-CHAN, a town of Corea; 30 miles N.W. of Long-kouan.

SOVERDEM, a town of Italy; 3 miles N. of Belluno.

SOVEREIGN, Supreme, the chief and higheſt Being, or the Almighty; a term, in ſtrictneſs, only applicable to God.

The word is French, *ſouverain;* which Paſquier derives farther from the Latin *ſuperior*, the firſt in any thing; or he who is ſuperior to the reſt. Hence,

In the ancient French cuſtoms we meet with ſovereign maſter of the houſehold; ſovereign maſter of the foreſts; ſovereign maſter of the treaſury. Under Charles VI. the title ſovereign was given to bailiffs and ſeneſchals, with regard to their ſuperiority over prevots, and chatelains.

Sovereign, with regard to ſubjects, is applied to kings and princes, who are ſupreme and independent.

The authority of a ſovereign is only bounded by the law of God, of nature, and the fundamental laws of the ſtate. See King. See Sovereignty, *infra.*

Sovereign is alſo a title given to ſuch as are inveſted with certain rights and prerogatives, which belong only to ſovereigns; as the power of coining money, ſending agents to diets, to treat of war and peace, &c.

In which ſenſe the feudatories of the empire, and the tributaries of the grand ſignior, are called ſovereigns.

Sovereign is alſo applied to courts and judges, who have a power from a prince to decide the proceſſes of his ſubjects without appeal, or in the laſt reſort.

At Paris, under the old regime, there were five ſovereign companies: the parliament, the chamber of accounts, the court of aids, the grand council, and the court of monies.

In England we have but one ſovereign court, which is the houſe of lords.

Sovereign, in *Engliſh Coinage*, a gold coin of 20*s.* value, equal to the double ryal, which was coined by order of Henry VII. in the year 1485; and this was accompanied by the double ſovereign of 40*s.* Henry VIII., in 1527, added to the gold denominations ſovereigns of 22*s.* 6*d.*, and ryals of 11*s.* 3*d.*, angels of 7*s.* 6*d.*, and nobles at their old value of 6*s.* 8*d.* In 1546 the ſame prince, after raiſing the value of ſilver, and making it to gold as 1 to 5, ſtruck ſovereigns of the former value of 20*s.*, and half-ſovereigns in proportion. Upon the union of the crowns, James I. of England gave the ſovereign the name of unite, it being then of 20*s.* value. The ſovereign, which had been commonly termed the "broad-piece," under the Commonwealth aſſumed the uninvidious name of the twenty-ſhilling piece, which it retained till ſupplanted by that of the guinea, which was proclaimed in 1663, and to paſs for 20*s.* But it never went for leſs than 21*s.* by tacit and univerſal conſent. Pinkerton's Eſſ. on Medals, vol. ii.

SOVEREIGNTY, in *Political Economy*, denotes that public authority, which commands in civil ſociety, ordering and directing what each is to perform, in order to obtain the end of its inſtitution. This authority belonged originally and eſſentially to the body of the ſociety, to which each member ſubmitted, and ceded the rights he received from nature, to conduct himſelf in every thing as he pleaſed, according to the dictates of his own underſtanding, and to do himſelf juſtice. But the body of this ſociety does not always retain this ſovereign authority: it frequently truſts it to a ſenate, or to a ſingle perſon. This ſenate, or this perſon, is then the ſovereign. (See Sovereign, *ſupra.*) It is evident that men form a political ſociety, and ſubmit to laws, ſolely for their own ſafety and advantage. The ſovereign authority is then eſtabliſhed, only for the common good of all the citizens; and it would be abſurd to think that it could change its nature, on its paſſing into the hands of a ſenate, or a monarch. Flattery, therefore, cannot diſown, without rendering itſelf equally ridiculous and odious, that the ſovereign is only eſtabliſhed for the ſafety of the ſtate, and the advantage of ſociety.

A good prince, a wiſe conductor of ſociety, ought to have his mind impreſſed with this great truth, that the ſovereign power is only entruſted with him for the ſafety of the ſtate, and for the happineſs of all his people; that he is not permitted to ſeek himſelf in the adminiſtration of affairs, to propoſe his own ſatisfaction, or his private advantage; but that he ought to direct all his views, all his ſteps, to the great advantage of the ſtate and people who have ſubmitted to him. How noble a ſight is it, ſays the admirable Vattel, to ſee a king of England acquaint his parliament with all his principal operations; aſſure that body, the repreſentatives of the nation, that he propoſes no other end but the glory of the ſtate, and the happineſs of his people; and affectionately thank all who concur with him in ſuch ſalutary views! Certainly a monarch, who makes uſe of this language, and proves his ſincerity by his conduct, is, in the opinion of the wiſe, the only great man. But for a long time a baſe flattery has, in moſt kingdoms, cauſed theſe maxims to be forgotten. A crowd of ſervile courtiers without difficulty perſuade a proud monarch, that the nation was made for him, and not he for the nation. He ſoon conſiders the kingdom as his patrimony, and his people as a herd of cattle, from which he may obtain riches, and diſpoſe of them ſo as beſt to anſwer his views, and gratify his paſſions. From thence ariſe thoſe fatal wars, undertaken by ambition, reſtleſſneſs, hatred, and pride: from thence thoſe oppreſſive taxes, diſſipated by luxury, or ſquandered upon miſtreſſes and favourites: from thence, in fine, are important poſts given by favour, while public merit is neglected, and every thing that does not immediately intereſt the prince, abandoned to miniſters and ſubalterns. Who can obſerve, in this unhappy government, authority eſtabliſhed for the public welfare? A great prince will be on his guard, even againſt his virtues. Let us not ſay, with ſome writers, that private virtues are not the virtues of kings; the maxim of ſuperficial politicians, or of thoſe who are very inaccurate in their expreſſions. Goodneſs, friendſhip, gratitude, are ſtill virtues of the throne; and would to God they were to be always ſo! But a wiſe king does not, without diſcernment, give himſelf up to their impreſſions. He cheriſhes them, he cultivates them in his private life; but in ſtate-affairs he liſtens only to juſtice and ſound politics. And why? becauſe he knows that the government was truſted to him only for the happineſs of ſociety; and that, therefore, he ought not to conſult his own pleaſure in the uſe he makes of his power. He tempers his goodneſs with wiſdom. He gives to friendſhip his domeſtic and private favours; he diſtributes poſts and employments according to merit; public rewards to ſervices done to the ſtate. In a word, he uſes the public power only with a view to the public welfare. All this is comprehended in the fine ſaying of Lewis XII., "A king of France does not revenge the injuries of a duke of Orleans."

A political ſociety is a moral perſon, as it has an underſtanding and a will, of which it makes uſe for the conduct of its affairs, and is capable of obligations and laws. When, therefore, a people confer the ſovereignty on any one perſon, they inveſt him with their underſtanding and will; and make over to him their obligations and rights, ſo far as relates to the adminiſtration of the affairs of ſtate, and the exerciſe of the public authority; thus the ſovereign, or conductor of the ſtate, becoming the ſubject, in which reſide the obligations and rights relative to government, in him is found the moral perſon, who, without abſolutely ceaſing to exiſt in the nation, acts from thence forwards only in and by him. Such is the origin of the repreſentative character attributed to the ſovereign. He repreſents the nation in all the affairs it was capable of managing as ſovereign. It does not debaſe the dignity of the greateſt monarch to attribute to him this repreſentative character; on the contrary, nothing can make him ſhine with greater luſtre: for by this means the monarch unites, in his own perſon, all the majeſty that belongs to the entire body of the nation.

The ſovereign, thus clothed with the public authority, with every thing that conſtitutes the moral perſonality of the nation, is under the obligations of that nation, and inveſted with its rights.

Every thing that concerns the general duties of a nation towards itſelf, particularly regards the ſovereign. He is the depoſitary of the empire, and of the power of commanding whatever relates to the public welfare: he ought, therefore, as a tender and wiſe father, and as a faithful adminiſtrator, to watch for the nation, to take care of preſerving it, to render it more perfect, to better its ſtate, and to ſecure it, as much as he is able, from every thing that threatens its ſafety, or its happineſs.

The prince derives his authority from the nation; and it is exactly equal to what they have entruſted him with. If the nation has ſimply and ſtrictly inveſted him with the ſovereignty without limitation, or diviſion, he is ſuppoſed to be inveſted with all the prerogatives, without which the ſovereign command, or authority, could not be exerted in the manner moſt conducive to the public welfare. Theſe are called *regal prerogatives*, or *the prerogatives of majeſty*.

But the ſovereign power is limited and regulated by the fundamental laws of the ſtate: thoſe laws ſhew the prince the extent and bounds of his power, and the manner in which it ought to be exerted. The prince is, therefore, ſtrictly obliged not only to reſpect, but alſo to ſupport them. The conſtitution and the fundamental laws are the plan on which the nation has reſolved to endeavour the obtaining of happineſs: the execution is entruſted to the prince. If he religiouſly follows this plan; if he regards the fundamental laws as inviolable and ſacred rules, and knows that the moment he deviates from them, his commands become unjuſt, and are no leſs than a criminal abuſe of the power with which he is entruſted. He is, in virtue of this power, the guardian and defender of the laws; and being obliged to puniſh any one who ſhall preſume to violate them, he himſelf ought not to trample them under his feet.

While the laws of a ſociety, over which a ſovereign preſides, ſubſiſt, he ought religiouſly to maintain and obſerve them. This is no leſs his true intereſt than his duty. But in explaining this ſubmiſſion of the prince to the laws, Vattel obſerves, that he is above all civil penal laws. The majeſty of a ſovereign will not ſuffer his being puniſhed like a private perſon; and his employments are too ſublime to admit of his being troubled, under the pretence of a fault that does not directly concern the government of the ſtate. His perſon, therefore, ſhould be regarded as inviolable. Nevertheleſs, this high attribute of ſovereignty is no reaſon why a nation ſhould not curb an inſupportable tyrant, call him even to an account, reſpecting in his perſon the majeſty of his rank, and withdraw itſelf from his obedience. To this indiſputable right a powerful republic owes its birth. The tyranny exerciſed by Philip II. in the Netherlands, excited thoſe provinces to riſe: ſeven of them, cloſely confederated, bravely maintained their liberties, under the conduct of a hero of the houſe of Orange; and Spain, after ſeveral vain and deſtructive efforts, acknowledged them ſovereign and independent ſtates. If the authority of the prince is limited and regulated by the fundamental laws, the prince, on leaving the bounds preſcribed him, commands without any right, and even without a juſt title: the nation, then, is not obliged to obey him, but may reſiſt his unjuſt enterprizes. As ſoon as he attacks the conſtitution of the ſtate, the prince breaks the contract which bound the people to him; the people became free by the act of the ſovereign, and ſee nothing in him but an uſurper who would load them with oppreſſion. This truth is acknowledged by every ſenſible writer, whoſe pen is not enſlaved by fear, or rendered venal by intereſt. But ſome celebrated authors maintain, that if the prince is inveſted with the ſupreme command in a full and abſolute manner, nobody has a right to reſiſt him, much leſs to curb him, and that the nation has no reſource left but to ſuffer and obey with patience. This is founded upon the ſuppoſition that ſuch a ſovereign need not give an account to any perſon of the manner in which he governs; and that if the nation might controul his actions and reſiſt him, where they were found to be unjuſt, his authority would no longer be abſolute; which would be contrary to this hypotheſis. They ſay, that an abſolute ſovereign poſſeſſes completely all the political authority of the ſociety, in which nobody can oppoſe him; if he abuſes it, he does ill, indeed, and wounds his conſcience, but that his commands are not the leſs obligatory, as being founded on a lawful right to command: that the nation, by giving him abſolute authority, had reſerved nothing to itſelf, and had ſubmitted to his diſcretion, &c. We might ſatisfy ourſelves with anſwering, that in this light there is not any ſovereign who is completely and fully abſolute. But in order to remove all theſe vain ſubtilties, let us remember the eſſential end of civil ſociety: is it not to labour in concert for the common happineſs of all? Is it not with this view that every citizen ſtrips himſelf of his rights, and reſigns his liberty? Was it in the power of the ſociety to make ſuch uſe of its authority as to deliver up itſelf, and all its members, without relief, to the diſcretion of a cruel tyrant? No, certainly, ſince it had no right itſelf, if it was diſpoſed to it, to oppreſs a part of the citizens. When it, therefore, conferred the ſupreme and abſolute government, without an expreſs reſerve, it was neceſſarily with the tacit reſerve, that the ſovereign ſhould uſe it for the ſafety of the people, and not for their ruin. If he becomes the ſcourge of the ſtate, he degrades himſelf; he is no more than a public enemy, againſt whom the nation may and ought to defend itſelf; and if he has carried his tyranny to the utmoſt height, why ſhould even the life of ſo cruel and perfidious an enemy be ſpared? Who preſumes to blame the Roman ſenate, that declared Nero an enemy to his country?

But it is of the utmoſt importance to obſerve, that this judgment can only be paſſed by the nation, or by the body by which it is repreſented; and that the nation itſelf cannot make any attempt on the perſon of the ſovereign, but in caſes of extreme neceſſity, and when the prince, by violating the laws, and threatening the ſafety of his people, puts them in a ſtate of war againſt them. The perſon of the ſovereign, the very intereſt of the nation declares ſacred and inviolable; but not that of an unnatural tyrant, and an enemy of the public. We ſeldom ſee ſuch monſters as Nero.

As ſoon as a nation acknowledges a prince for its lawful ſovereign, all the citizens owe him a faithful obedience. He can neither govern the ſtate, nor perform what the nation expects from him, if he is not punctually obeyed. Subjects then have no right, in doubtful caſes, to queſtion the wiſdom or juſtice of their ſovereign's commands; this examination belongs to the prince: his ſubjects ought to ſuppoſe, if there be a poſſibility of doing it, that all his orders are juſt and ſalutary: he alone is accountable for the evil that may reſult from them.

In the mean time, this ought not to be entirely a blind obedience. No engagement can oblige, or even authorize, a man to violate the laws of nature. All authors who have any regard to conſcience, or modeſty, agree, that a perſon ought not to obey ſuch commands as are evidently contrary to the laws of God. Thoſe governors of places, who bravely refuſed to execute the barbarous orders of Charles IX. to the famous St. Bartholomew, have been univerſally praiſed; and the court did not dare to puniſh them, at leaſt openly. "Sire," ſaid the brave Orte, governor of Bayonne, in his letter, "I have communicated your majeſty's command to your faithful inhabitants and warriors in the garriſon; and I have found there only good citizens and brave ſoldiers: not one hangman; therefore, both they and I moſt humbly entreat your majeſty, to be pleaſed to employ our arms and lives in things that are poſſible, however hazardous they may be, and we will exert ourſelves to the laſt drop of our blood." The count de Tende, Charney, and others, replied to thoſe who brought them the orders of the court, that they had too great a reſpect for the king, to believe that ſuch barbarous orders came from him.

It is not eaſy to determine in what caſes a ſubject may not only refuſe to obey, but even reſiſt a ſovereign, and by force repel force. However, when the injuries, which ſociety ſuffers, are manifeſt and atrocious; when a prince, without any apparent reaſon, is reſolved to deprive us of life, or of thoſe things, the loſs of which would render life bitter, who can diſpute our right to reſiſt him? Self-preſervation is not only a law of nature, but an obligation impoſed by nature, and no man can entirely and abſolutely give it up to another. And though he might give it up, can he be conſidered as having done it by his political engagements, when he entered into ſociety only to eſtabliſh his own ſafety upon a more ſolid baſis? The welfare of ſociety does not require ſuch a ſacrifice; and as Barbeyrac well obſerves in his notes on Grotius, "If the public intereſt requires, that thoſe who obey ſhould particularly ſuffer ſomething; it is not leſs for the public intereſt that thoſe who command, ſhould be afraid of carrying their patience to the utmoſt extremity." The prince who violates all laws, who obſerves no meaſures, and who would in his tranſports of fury take away the life of an innocent perſon, ſtrips himſelf of his royalty, and is no more than an unjuſt and outrageous mortal, againſt whom his people are allowed to defend themſelves. But he who, after having loſt all the ſentiments of a ſovereign, diveſts himſelf even of the appearances and exterior conduct of a monarch, degrades himſelf; he no longer retains the ſacred perſon of a ſovereign, and cannot retain the prerogatives attached to his ſublime character. However, if this prince is not a monſter, if he is furious only from a juſt paſſion, and is ſupportable to the reſt of the nation; the reſpect we ought to pay to the tranquillity of the ſtate is ſuch, and the reſpect of ſovereign majeſty ſo powerful, that we are ſtrictly obliged to ſeek every other means of preſervation, rather than to put his perſon in danger. Every one knows the example ſet by David: he fled; he kept himſelf concealed, to ſecure himſelf from Saul's fury; and more than once ſaved the life of his perſecutor. When the reaſon of Charles VI. of France was ſuddenly diſordered by a fatal accident, he in his fury killed ſeveral of thoſe who ſurrounded him: none of them thought of ſecuring his own life, at the expence of that of the king; they only endeavoured to diſarm him, and to make him maſter of himſelf: they did their duty like brave men and faithful ſubjects, in expoſing their lives, to ſave that of this unfortunate monarch. We owe this ſacrifice to the ſtate and to ſovereign majeſty. Furious from the diſorder of his organs, Charles was not guilty; he might recover his health, and again become a good king.

We ſhall here further obſerve, that a ſovereign is undoubtedly allowed to take miniſters, to eaſe him in the painful office of government; but he ought never to abandon his authority to them. Miniſters ought only to be inſtruments in the hands of the prince; he ought conſtantly to direct them, and continually endeavour to know whether they follow his inſtructions. Miniſters, however, who undertake this charge, become reſponſible to the ſtate for their conduct; for the advice which they are ſuppoſed to give to the ſovereign, and for the meaſures which they adopt and purſue. Vattel's Law of Nations, b. i. ch. 4.

SOVERICK, in *Geography*, formerly known by the name of *Sauro*, a town of the pachalic of Orfa, a pachalic which is almoſt entirely encircled by the windings of the Euphrates and the river Khabour, and occupying a conſiderable portion of the moſt barren part of Meſopotamia. The town is ſituated, according to Niebuhr, in N. lat. 37° 48′, and contains about 500 inhabitants, with three moſques, and a ſtrong caſtle. The country to the ſouth of the parallel of Soverick is, for the moſt part, flat, ſandy, and uncultivated, and inhabited by tribes of wandering Arabs, who pitch their tents on the banks of the rivers, and in the vicinity of ſprings. From Soverick to Diarbekir it is more mountainous, and better inhabited.

SOUF, or VOSTANI, the middle diſtrict of Egypt, between the Bahira and Said.

SOUFFEL, a river of France, which runs into the Rhine, four miles below Straſburg.

SOUFFLEUR, Fr., the bellows-blower of an organ.

SOUFFLOT, JAMES-GERMAIN, in *Biography*, an eminent architect, was born in 1714 at Irancy, near Auxerre. His father, an advocate in parliament, deſtined him for his own profeſſion, and ſent him, while very young, to Paris for education; but he felt a taſte and inclination for the ſcience of architecture. Having been employed for ſome time in that art at Lyons, he went into Italy, where, by his talents and induſtry, he was admitted one of the king's penſioners. It being reſolved that ſeveral public buildings ſhould be erected at Lyons, he was recommended to undertake a part of the work, by the director of the French academy at Rome; and the conſtruction of the exchange and the hoſpital was committed to him. The noble ſimplicity of the hoſpital, together with its excellent adaptation to the object for which it was intended, were univerſally admired, and raiſed him to high reputation as an artiſt. He was, after this, employed to build the concert-room and theatre of the ſame city. He next travelled into Italy, and on his return he ſettled at Paris, where he was ſucceſſively made controller of the buildings at Marly and the Tuilleries, member of the academies of architecture and painting, knight of St. Michael, and intendant of the royal buildings. In 1757 he laid the foundation of the church of St. Genevieve, of which he was able only to finiſh the portal, the nave, and the towers. In this buſineſs he ſubjected himſelf to ſome ſevere criticiſm, eſpecially with reſpect to the poſſibility of erecting the intended dome upon the baſes deſigned to bear it; though ſome exact calculations juſtified his plan. The criticiſms and unfriendly remarks of his rivals were more than his temper, naturally irritable, could bear; and he died, partly of chagrin, in the year 1780, at the age of 67. Beſides the public works already mentioned, he executed many others, which diſplay the powers of a great artiſt; and after his death, M. Dumont, profeſſor of architecture, publiſhed a book of Deſigns, which he had left behind him, under the title of "Elevations et Coupes de quelques Edifices de France et d'Italie, deſignèes par feu M. Soufflot, Architecte du Roi, et gravèes par ſes Ordres." Though Soufflot was rough and haſty in his manners, he was kind and friendly; whence he obtained the name of *le Bourru Bienfaiſſant*.

SOUFFRIERE BAY, in *Geography*, a bay on the eaſt coaſt of the iſland of Dominica. N. lat. 15° 31′. W. long. 61° 17′.

SOU-FONG, a town of China, of the third rank, in Kiang-nan; 47 miles S.W. of Ngan-king.

SOUGH, in *Agriculture*, a covered drain of any ſize, but commonly of the more large kind. Sough drains are moſt commonly employed in the buſineſs of ſpring-draining, though occaſionally in other modes. See SPRING-*Drain* and SPRING-*Draining*.

SOUGH, otherwiſe called an *Adit*, in *Mineralogy*, is a paſſage like a vault cut out under the earth, to drain the water from the mines.

In a canal, it denotes a ſmall culvert or leading.

SOUHAITOU, in *Geography*, a town of Thibet; 28 miles W.N.W. of Yolotou Hotun.

SOUI, a city of China, of the ſecond rank, in Hou-quang; 527 miles S. of Peking. N. lat. 31° 48′. E. long. 112° 40′.

SOUI-CHONTO, a town of Chineſe Tartary, in the country of Hami. N. lat. 41° 8′. E. long. 94° 37′.

SOVIESE, a town of European Turkey, in Moldavia; 44 miles W. of Birlat.

SOUI-KI, a town of China, of the third rank, in Quang-tong; 30 miles N. of Louy.

SOUILLAC, a town of France, in the department of the Lot, and chief place of a canton, in the diſtrict of Gourdon. The place contains 1654, and the canton 8158 inhabitants, on a territory of 182½ kiliometres, in 10 communes.

SOUILLY, a town of France, in the department of the Meuſe, and chief place of a canton, in the diſtrict of Verdun. The place contains 792, and the canton 7528 inhabitants, on a territory of 230 kiliometres, in 21 communes.

SOUIN-HING, a town of China, of the third rank, in Hou-quang; 20 miles E.S.E. of Tſin.

SOUI-PING, a town of China, of the third rank, in Ho-nan; 17 miles W.N.W. of Yun-hing.

SOUI-TCHEOU, a city of China, of the firſt rank, in Se-tchuen, at the conflux of the rivers Yan and Kincha; 850 miles S.W. of Peking. N. lat. 28° 40′. E. long. 104° 23′.

SOUI-TE, a city of China, of the ſecond rank, in the province of Chen-ſi, on the Voutin river; 337 miles W.S.W. of Peking. N. lat. 37° 38′. E. long. 109° 34′.

SOUI-YANG, a town of China, of the third rank, in Se-tchuen; 20 miles N.N.E. of Tſun-y.

SOUKAPURA, a kingdom on the ſouth coaſt of the iſland of Java.

SOUKENE, a town of Africa; 130 miles S. of Tripoli.

SOUKERKE, a town of France, in the department of the Lys; 5 miles N.W. of Bruges.

SOUKETON, a river of New Hampſhire, which runs into the Merrimack, N. lat. 42° 48′. W. long. 71° 30′.

SOU-KISE, a town of China, in Hou-quang, on the river Lo; 55 miles N.N.W. of Pao-king.

SOUL, ANIMA, a ſpirit adapted to an organized body. See SPIRIT and BODY.

Many of the ancient philoſophers aſſerted an ANIMA *Mundi* (which ſee), a ſoul which moved and animated the machine of the univerſe, and gave action to all natural cauſes. This doctrine Plato handles very fully in his Timæus. (See PLATONISM.) For the doctrine of the Stoics on this ſubject, ſee STOICS. See alſo PHERECYDES.

The ancient Indians, who poſſibly derived their notions of God and providence from the Perſian Zoroaſter, conceived God to be the ſoul of the world, a rational and intellectual light, from which all good is derived, and the chief ſeat of whoſe divinity is the ſun. Their notion of divine providence, deduced from that of the ſoul of the world, probably extended no farther than that this principle is neceſſarily the firſt ſpring of all motion, life, and enjoyment; and fell far ſhort of that wiſe and gracious voluntary ſuperintendance, which is the Chriſtian idea of Providence.

Others have given particular ſouls to all the heavenly bodies, the ſun, ſtars, earth, &c. to regulate their motions. The philoſophers, many of them, allow of two, and others of three, kinds of ſouls; *viz.* a

SOUL, *Rational,* which they hold to be divine, and infuſed by the breath of God. This they call the ſpirit, and in this they ſuppoſe the intellect and will to be ſeated.

SOUL, *Senſitive,* or *Irrational,* which man has in common with brutes; which is formed out of the elements, and in which they apprehend the paſſions and appetites are ſeated.

SOUL, *Vegetative,* which we have in common with plants; and, as the firſt is the principle of reaſon and underſtanding, or that in us which thinks and underſtands; and the ſecond, the principle of life; this is the principle of growth, nutrition, and vegetation.

The firſt ancient philoſopher who taught the immortality of the ſoul, is ſaid to have been Pherecydes. (See his article.) The human mind, according to the doctrine of the ancient Indians (ſee BRACHMANS), is of celeſtial origin, and has a near relation to God. When it departs from the body, it returns to its parent, who expects to receive back the ſouls which he has ſent forth. The human ſoul they repreſented as of divine original, becauſe, with all the other eaſtern nations, they conceived it to be a particle, or an emanation, of that intellectual fire, by which they believed the univerſe to be animated. Their doctrine of the return of the ſoul to God, which ſome have confounded with the Chriſtian doctrine of the reſurrection, ſeems to have meant nothing more than that the ſoul, after being diſengaged from the groſſer material body, would be reunited to the fountain of all being, the ſoul of the world. For the opinion of the Egyptians concerning the human ſoul, we refer to the article EGYPT.

Among the northern nations it was a generally received opinion, that the human ſoul was of divine original, rational and immortal. That this was the univerſal doctrine of the Celts, whether Gauls, Britons, Germans, or other nations, is unanimouſly atteſted by the Greek and Roman writers, and by the remains of northern antiquities. Cæſar informs us (Bell. Gall. lib. vi. c. 14.), that the firſt doctrine of the Gallic Druids was, that the ſoul of man is immortal; and Pomponius Mela (lib. iii. c. 2.) ſays, that one of their doctrines, which was divulged among the people in order to inſpire them with martial courage, was, that the ſoul is immortal. This account is confirmed by Valerius Maximus (l. ii. c. 6.), Strabo (l. iv.), and other hiſtorians. And the fables every where received among the Celts concerning a future ſtate, leave no room to doubt, that the doctrine of the immortality of the ſoul was generally received among them.

> "Without or breath, or reaſoning pow'rs, or ſpeech,
> Or vital blood, or the fair human face,
> Aſkus and Emla lay: till Odin bade
> Them live, Hænerus kindled in their breaſt
> The lamp of mind, and Lædur through their veins
> Pour'd forth the purple ſtream; thus man aroſe,
> Graceful in youth, an animated form."

The hiſtory of all the northern nations abounds with facts, which prove that their contempt of death originated from an expectation of immortality. It does not, however, certainly appear, what kind of immortality theſe nations expected. According to Cæſar (l. ii. c. 6.) and Diodorus Siculus (l. i.), they thought, that the ſoul at death paſſes from one body to another. This doctrine of tranſmigration is alſo aſcribed to them by Lucan (Pharſ. l. i. v. 454.)

> "If dying mortals doom they ſing aright,
> No ghoſts deſcend to dwell in dreadful night;
> No parting ſouls to griſly Pluto go,
> Nor ſeek the dreary ſilent ſhades below:
> But forth they fly, immortal in their kind,
> And other bodies in new worlds they find:
> Thus life for ever runs its endleſs race,
> And, like a line, death but divides the ſpace." Rowe.

On the contrary, Pomponius Mela repreſents the Celts as expecting to paſs, after death, into the inviſible world. And this notion beſt agrees with the accounts, which are given by various writers, of the funeral ceremonies practiſed in the northern nations, particularly that of committing to the funeral pile, or to the ſepulchre, whatever had been dear to the deceaſed. It is alſo moſt conſonant to the language of the ancient Edda, which every where repreſents the future life, as an aſſembly of good or bad men, in a ſtate of reward or puniſhment, and only ſpeaks of a return to life for the purpoſe of reuniting the ſoul and body, after the ſoul has paſſed through a neceſſary courſe of purification, previouſly to its admiſſion into the regions of the happy. From this ſtate of purgation none were to be excuſed, except thoſe who had voluntarily expoſed themſelves to death in battle: and hence it was, that they who fell in war were deemed to have made a glorious and happy exit from life, whilſt they who died by ſickneſs were thought to have periſhed ſhamefully and wretchedly. See CELTS and DRUIDS.

Of the opinion of Socrates concerning the human ſoul, we have already given an account under the article SOCRATES. For Plato's opinion, ſee PLATONISM. For an account of the Ariſtotelian doctrine on this ſubject, ſee ARISTOTLE. Strabo taught that the ſeat of the ſoul is in the middle of the brain; and that it only acts by means of the ſenſes. (See STRABO.) Dicearchus, of whom Cicero ſpeaks as a learned and eloquent writer, maintained, that there is no ſuch thing as mind, or ſoul, either in man or beaſt; that the principle, by which animals perceive and act, is equally diffuſed through the body, is inſeparable from it, and expires with it. For the opinion of the Stoics, ſee STOICS. For the opinion of Pythagoras and his followers, ſee PYTHAGOREANS. See alſo EMPEDOCLES, DEMOCRITUS, and HERACLITISM.

The Epicureans took the ſubſtance of the ſoul, we mean of the rational ſoul, to be a ſubtile air, compoſed of their atoms, or primitive corpuſcles. See EPICUREANS.

The tenets of the modern Platoniſts with regard to the ſoul of man, may be found in the writings of Plotinus, Jamblichus, and Porphyry, who may be reckoned among the principal perſons that belonged to the Eclectic ſect. Plotinus taught, that the firſt principle of the univerſe, which is diſtinct from the univerſe, is the cauſe of intellectual life and the ſource of eſſence and being, ſimple in its own nature, and having no place, and deſtitute both of motion and reſt; infinite and unlimited, eſſentially good, and fair and beautiful, the author of all that is lovely, the beginning and end of beauty. From this firſt principle proceeds mind, or intellect, and ſoul, or the active principle. The primary eſſential good is the centre; mind, the light emerging from it, and remaining fixed; ſoul, the motion of the emerging light; and body, the opaque ſubſtance, which is illumined by the ſoul. From the emanative energy of mind is produced ſoul, or the active principle of life. This divine principle is the fountain, whence all life is derived. It ſubſiſts, as well as intellect, within the divine eſſence, and is therefore ὑπερκόσμιον, ſupramundane. This is the immediate ſource of the principle which animates the world, ἐγκόσμιον, and which is diffuſed, in various portions, through animated nature. The ſouls of men and inferior animals conſtitute the common limit between the intellectual and ſenſible world. The human ſoul is derived from the ſupramundane ſoul, or firſt principle of life, and is in this reſpect ſiſter to the ſoul of the world. Souls are not in the body as their place, nor as their receptacle, nor as their ſubject, nor as a part of a whole, nor as form united to matter, but ſimply as the animating principle; and it is in this reſpect only, that we know the ſoul to be preſent with the body. The power of the ſoul is diffuſed through every part of the body; and though it be ſaid to reſide in its chief inſtrument the brain, it is incorporeal, and exiſts entirely every where within the ſphere of its energy. Partaking of the nature of real being, it is immutable. It is the principle of motion, moving itſelf, and communicating motion to bodies. The vices and infelicities of the ſoul, are wholly derived from its union with the body.

Souls, in the periodical revolutions of nature, ſeparate themſelves from their fountain, and deſcend into the lower regions of the world. In their paſſage, they attract to themſelves an ethereal vehicle, and at laſt ſink into animal bodies, as into a cavern or ſepulchre. But when, by the power of reminiſcence, they again turn themſelves to the contemplation of intelligible and divine natures, they regain their freedom. God, on account of his greatneſs, is not known by intelligence or ſenſe, but by a kind of intuition ſuperior to ſcience, by means of which the ſoul can ſee him in his real nature, as the fountain of life, mind, and being, and the cauſe of good. A ſoul which has attained to this viſion of God will lament its union with the body, and will rejoice to leave its priſon, and return to the divine nature from which it proceeded. After death, the ſouls of men paſs into other animals, or aſcend into ſuperior regions, and are converted into beings of an higher order, according to their preſent degree of defilement or of purification.

The human ſoul, according to Jamblichus, has an innate knowledge of God, prior to all reaſoning, having originally derived its eſſence from, and ſubſiſted in, the divine nature. By the intervention of dæmons, it enjoys communications with the ſuperior divinities, and with God himſelf. Prayers, hymns, luſtrations, and ſacrifices are the means by which this intercourſe is maintained. The mind of man, as we learn from the writings of Porphyry and others, originally a portion of the divine nature, having fallen into a ſtate of darkneſs and defilement by its union with the body, is to be gradually emancipated from the chain of matter, and by contemplating real entities, to riſe to the knowledge and viſion of God. The end of philoſophy is, therefore, the liberation of the ſoul from its corporeal impriſonment. For this purpoſe it muſt paſs through the ſeveral ſtages of the human and divine virtues. The human virtues are phyſical, economical, and political; or thoſe which reſpect the care of the body, and the offices of domeſtic and civil life. The divine virtues are purgative, theoretic, and theurgic: the firſt claſs conſiſts in bodily abſtinence, and other voluntary mortifications; the ſecond comprehends all thoſe exerciſes of the intellect and imagination, by which the mind contemplates abſtract truth, and intelligible natures; the third includes thoſe religious exerciſes, by which the philoſopher is qualified for, and admitted to, an immediate intercourſe with ſuperior beings, attains a power over dæmons, and aſcends ſo far above the ordinary condition of humanity, as to enjoy the viſion of God in this life, and to return, at death, to the divine mind, whence it firſt proceeded. Thus, we have given a ſpecimen of the viſionary ſubtleties of the Alexandrian philoſophy, or that of the Eclectic ſect.

According to the popular doctrine of the Jews, in and after the tenth century, the ſoul of man is a thinking ſubſtance, having three faculties, the vegetative, the ſenſitive, and the rational: it is poſſeſſed of liberty, and is immortal. After death it is not immediately admitted to celeſtial joys, but wanders in this world, chiefly about its body, during which time it is tormented by evil dæmons; in this purgatory it is cleanſed from its ſtains; after which it paſſes into either bodies of men, or inferior animals. There will be a reſurrection of the bodies of dead men, and an univerſal judgment, which will be ſucceeded by a ſtate of retribution. The ſoul will enjoy eternal life in paradiſe, and the wicked will be conſigned to the infernal regions; the Jew for a time, but the infidel for ever. The world will be deſtroyed; but the materials of which it is compoſed will remain. Thus the modern Jews blended tenets, which they derived from their ſacred ſcriptures, with opinions which they borrowed from their Gentile neighbours. They firſt ſuffered their doctrines to be corrupted by the Egyptian philoſophy, and afterwards learned from the Saracens to reaſon, after the Peripatetic manner, upon metaphyſical ſubjects; of which examples may be ſeen in the writings of Maimonides, and in the book Coſri. The human ſoul, according to the Cabbaliſtic doctrine, proceeding by emanation from the Deity, is an incorporeal ſubſtance, of the ſame nature with the divine intellect. Being united to the body, one complex nature is produced, endued with reaſon, and capable of action. The human ſoul conſiſts of four parts, "nepheſh," or the principle of vitality; "ruach," or the principle of motion; "neſchamah," or the power of intelligence; and "jechidah," a divine principle, by means of which it contemplates ſuperior natures, and even aſcends to the Enſophic world. All ſouls were produced at once, and pre-exiſted in Adam. Every human ſoul has two guardian angels, produced by emanation, at the time of the production of ſouls. The mind of man is united to the divine mind, as the radius of a circle to its centre. The ſouls of good men aſcend above the manſion of angels, and are delighted with the viſion of the firſt light, which illuminates all the world.

The doctrine of the Arabians, ſtated by Al-Gazel, is, that the ſouls of men are immortal, and that their bodies will be raiſed from the dead. In the interval between death and the reſurrection, ſouls remain in an intermediate ſtate; and after the reſurrection the good and faithful ſhall be rewarded, and the wicked and unbelieving ſhall be puniſhed; but they who, after having ſuffered puniſhment, ſhall confeſs one God, will, through his favour, be releaſed from their confinement, and placed among the bleſſed.

The Carteſians make thinking the eſſence of the ſoul; and, from this principle, deduce its immateriality and immortality. But, according to Mr. Locke, &c. the principle is falſe; nor is there any need to define the ſoul a ſubſtance that thinks, to prove it immortal. It is enough that the ſoul be capable of thinking, and that it produce its own thoughts, without making thinking its eſſence. It is no more eſſential to the ſoul to think than to will; for a thing I can conceive the ſoul without, cannot be its eſſence.

Again, if thought be the eſſence of the ſoul, as a thing cannot produce itſelf, its own being, or eſſence; the ſoul does not produce its own thoughts, nor its own will: and thus it is brought to the condition of brutes, or even of inanimate bodies, without any action, any liberty, &c.

If the Carteſians only mean this of the faculty of thinking, they do wrong even to call this the eſſence of the ſoul. It is no more its eſſence than the faculty of willing is. And we conceive ſomething in the ſoul prior to both thoſe faculties.

The ſoul is a ſpiritual ſubſtance, proper to inform or animate a human body: and, by its union with this body, to conſtitute a reaſonable animal or man. This is its eſſence, and this its definition.

It muſt be owned, the Carteſians prove the ſpirituality and immortality of the ſoul, from its thinking, exceedingly well; but they are not to have the honour of this proof as their own invention. All the great philoſophers uſed it before them, and uſe it ſtill.

For an account of Leibnitz's doctrine concerning the ſoul, ſee LEIBNITZ, LEIBNITZIAN *Philoſophy*, MONAD, and *Pre-eſtabliſhed* HARMONY.

Spinoza, and his followers, allowing only of one kind of ſubſtance, *viz.* matter; maintain the ſoul to be of the ſame ſubſtance with the body, *viz.* material. See SPINOZISM.

The doctrine of the materiality of the human ſoul has been adopted and maintained by ſeveral modern writers; and even by thoſe who have diſtinguiſhed themſelves as able and zealous advocates in the cauſe of religion, both natural and revealed. In this number we may reckon Dr. Prieſtley, who, rejecting the commonly received notion of matter, (ſee MATTER,) as an abſolutely impenetrable, inert ſubſtance, and premiſing, that the powers of ſenſation or perception, and thought, as belonging to man, have never been found but in conjunction with a certain organized ſyſtem of matter, maintains, that thoſe powers neceſſarily exiſt in, and depend upon, ſuch a ſyſtem. In proof of this doctrine, it is alleged, that perception and thought are not incompatible with the properties of matter, conſidered as a ſubſtance extended and endued with the powers of attraction and repulſion; and, therefore, if one kind of ſubſtance be capable of ſupporting all the known properties of man, true philoſophy, which will not authorize us to multiply cauſes or kinds of ſubſtance, without neceſſity, will forbid us to admit of any ſubſtance in the conſtitution of human nature, eſſentially different from matter. The proper ſeat of the powers of perception and thought, according to this writer, is the brain; becauſe, as far as we can judge, the faculty of thinking, and a certain ſtate of the brain, always accompany and correſpond to one another; and there is no inſtance of any man retaining this faculty, when his brain was deſtroyed; and whenever that faculty is impeded or injured, there is ſufficient reaſon to believe that the brain is diſordered in proportion. Dr. Prieſtley apprehends, that ſenſation and thought neceſſarily reſult from the organization of the brain, when the powers of mere life are given to the ſyſtem, and that they follow of courſe, as much as the circulation of the blood follows reſpiration; but he profeſſes to have no idea at all of the manner in which the power of perception reſults from organization and life.

To this reaſoning it has been replied, in general, that Dr. Prieſtley's account of matter does not anſwer to the common ideas of matter, or that it is not ſolid extenſion, or an impenetrable and inert ſubſtance, which is the only matter that is the object of natural philoſophy; but ſomething not ſolid, that exiſts in ſpace, and ſo far agreeing with ſpirit; and conſequently, if ſuch matter is, as he aſſerts, the only matter poſſible, it will follow, not that we have no ſouls diſtinct from our bodies, but that we have no bodies diſtinct from our ſouls, and that all in nature is ſpirit. Beſides, it has been farther urged, that a connection and dependence by no means prove ſameneſs.

From the dependence of actual ſenſations and thought on the brain, we have no more reaſon to conclude that the brain is the mind, than a ſavage who had never heard the muſic of a harpſichord, and did not ſee the hand that played upon it, would have to conclude, that it played upon itſelf, and was the muſician; becauſe he could trace all the ſounds to the inſtrument, and found that when the ſtrings were out of order, the muſic was diſturbed or deſtroyed. What experience teaches us is, that the exerciſe of the mental powers *depends* on the brain and the nerves; not that the mind *is* the brain and the nerves. We are ſure the mind cannot be the brain, becauſe the brain is an aſſemblage of beings; whereas the mind is one being.

It has been further objected by an anonymous writer (Edinb. Rev. N° XVII.), that it is unphiloſophical to claſs perception among the qualities of matter, when it is obvious, that it is by means of perception alone that we get any notion of matter or its qualities; and that it is poſſible, with perfect conſiſtency, to maintain the exiſtence of our perceptions, and to deny that of matter altogether. The other qualities of matter are perceived by us; but perception cannot be perceived; all we know about it is, that it is that by which we perceive every thing elſe. It ſounds ſomewhat abſurd and unintelligible, to ſay that perception is that quality of matter by which it becomes conſcious of its own exiſtence, and acquainted with its other qualities. It is plain that this is not a quality, but a knowledge of qualities: and that the percipient muſt neceſſarily be diſtinct from that which is perceived by it. We muſt always begin with perception; and the followers of Berkeley will tell us, that we muſt end there alſo. At all events, it certainly never entered into the head of any plain man to conceive, that the faculty of perception itſelf was one of the qualities with which that faculty made him acquainted; or that it could poſſibly belong to a ſubſtance, which his earlieſt intimations and moſt indeſtructible impreſſions taught him to regard as ſomething external and ſeparate.

The following lines, if we may be allowed to avail ourſelves of poetry in the illuſtration of a metaphyſical queſtion, forcibly expreſs the univerſal and natural impreſſion of mankind on this ſubject.

"Am I but what I ſeem, mere fleſh and blood?
A branching channel, and a mazy flood?
The purple ſtream, that through my veſſels glides,
Dull and unconſcious flows like common tides.
The pipes, through which the circling juices ſtray,
Are not that thinking I, no more than they.
This frame, compacted with tranſcendent ſkill,
Of moving joints, obedient to my will,
Nurſed from the fruitful glebe like yonder tree,
Waxes and waſtes: I call it *mine*, not *me*.
New matter ſtill the mouldering maſs ſuſtains;
The manſion changed, the tenant ſtill remains,
And, from the fleeting ſtream repair'd by food,
Diſtinct, as is the ſwimmer from the flood."

But, beſides the impropriety of making the faculty of perception a quality of the thing perceived, and of abſurdly converting our knowledge of the qualities of matter into another quality of the ſame ſubſtance, chargeable upon the doctrine of materialiſm, it is alleged that to call perception a *quality* at all, is a groſs and unwarrantable abuſe of language. Perception is an act or an event, a fact or a phenomenon, of which the percipient is conſcious; but it cannot be intelligibly conceived as a quality; and, leaſt of all, as a quality of that ſubſtance which is known to us as ſolid and extended. 1ſt. All the qualities of matter, it has been already ſtated, are perceived by the ſenſes; but the ſenſation itſelf cannot be ſo perceived: nor is it poſſible to call it an object of ſenſe, without the groſſeſt perverſion of expreſſion. 2dly. All the qualities of matter have a direct reference to ſpace or extenſion, and are conceived, in ſome meaſure, as attributes or qualities of the ſpace within which they exiſt. When we ſay that a particular body is ſolid, we mean merely that a certain portion of ſpace is impenetrable; when we ſay that it is coloured, we mean that the ſame portion of ſpace appears of one hue,—and ſo of the other qualities: but ſenſation or thought is never conceived to occupy ſpace, or to characterize it; nor can theſe faculties be at all conceived as definite portions of ſpace, endued with perceptible properties. In the third place, all the primary qualities of matter are inſeparable from it, and enter neceſſarily into its conception and definition. All matter muſt neceſſarily be conceived ſo extended, ſolid, and figured. It is obvious, however, that thought or ſenſation is not an inſeparable attribute of matter, as by far the greater part of matter is entirely deſtitute of it; and it is found in connection with thoſe parts which we term organized, only while they are in a certain ſtate, which we call alive. If it be ſaid, however, that thought may reſemble thoſe accidental qualities of matter, ſuch as heat or colour, which are not inſeparable or permanent; then we reply, that none of theſe things can properly be termed matter, more than thought or ſenſation; they are themſelves ſubſtances, or matter poſſeſſed of inſeparable and peculiar qualities, as well as thoſe which addreſs themſelves to the other ſenſes. Light is a material ſubſtance, from which the quality of colour is inſeparable; and heat is a material ſubſtance, which has univerſally the quality of exciting the ſenſation of warmth. If thought be allowed to be a ſubſtance in this ſenſe, it will remain to ſhew that it is material, by being referrible to ſpace, and liable to attraction, repulſion, condenſation or reflection, like heat or light.

Thought, as the advocates of materialiſm allege, is nothing elſe than motion; but, without attempting to define motion, it is ſufficient to obſerve, that it is not a quality of matter; it is an act, a phenomenon, or a fact; but it makes no part of the deſcription or conception of matter, though it only exiſts with reference to that ſubſtance. Let any man aſk himſelf, however, whether the motion of matter bears any ſort of reſemblance to thought or ſenſation; or whether it be even conceivable that theſe ſhould be one and the ſame thing? But, it is ſaid, we find ſenſation always produced by motion; and as we can diſcover nothing elſe in conjunction with it, we are juſtified in aſcribing it to motion. This is not the queſtion. It is not neceſſary to inquire, whether motion may *produce* ſenſation or not, but whether ſenſation *be* motion, and nothing elſe. It ſeems pretty evident that motion can produce nothing but motion or impulſe, and that it is at leaſt as inconceivable that it ſhould ever produce ſenſation in matter, as that it ſhould produce a ſeparate ſubſtance, called mind. But this is not the queſtion with the materialiſts. Their propoſition is, not that motion produces ſenſation, which might be as well in the mind as in the body; but that ſenſation is motion; and that all the phenomena of thought and perception are intelligibly accounted for by ſaying, that they are certain little ſhakings in the pulpy part of the brain.

That ſenſation may follow motion in the brain, or may even be produced by it, is conceivable at leaſt, and may be affirmed with perfect preciſion and conſiſtency; but that the motion is itſelf ſenſation, and that the proper and complete definition of thought and feeling is, that they are certain vibrations in the brain, is a doctrine that can only be wondered at, and that muſt be comprehended before it be anſwered.

No advocate for the exiſtence of mind, ever thought it neceſſary to deny that there was a certain bodily apparatus neceſſary to thought and ſenſation in man, and that on many occaſions the ſenſation was preceded or introduced by certain impulſes and correſponding movements of this material machinery; we cannot ſee without eyes and light, nor think without living bodies. All that they maintain is, that theſe impulſes and movements are not feelings or thought, but merely the occaſions of feeling and thought, and that it is impoſſible for them to confound the material motions which precede their ſenſations, with the ſenſations themſelves, which have no conceivable affinity with matter.

Dr. Prieſtley farther argues, that all our ideas either proceed from the bodily ſenſes, or are conſequent upon the perceptions of ſenſe; and hence infers, that the notion of the poſſibility of thinking in man, without an organized body, is not only deſtitute of all evidence from actual appearances, but is directly contrary to them. Moreover, if the mind was naturally ſo independent of the body, as to be capable of ſubſiſting by itſelf, and even of appearing to more advantage after the death of the body, as ſome of the advocates for an intermediate ſtate have maintained, it might, he ſays, diſcover ſome ſigns of its independence before its death, and eſpecially when the organs of the body were obſtructed, ſo as to leave the ſoul more at liberty to exert itſelf, as in a ſtate of ſleep or ſwooning, which moſt reſemble the ſtate of death, in which it is pretended that the ſoul is moſt of all alive, moſt active, and vigorous; but, judging by appearances, the reverſe of all this is the caſe. Beſides, if the mental principle was, in its own nature, immaterial and immortal, all its particular faculties would be ſo too; whereas we ſee that every faculty of the mind, without exception, is liable to be impaired, and even to become wholly extinct before death. Whence he infers, that the ſubſtance, or principle, in which theſe faculties exiſt, muſt be pronounced to be mortal too. He adds, if the ſentient principle in man be immaterial, it can have no extenſion, but every thing within it, or properly belonging to it, muſt be ſimple and indiviſible; and if this were not the caſe, the ſoul would be liable to corruption and death. But Dr. Prieſtley obſerves, that, whatever ideas are in themſelves, they are evidently produced by external objects, and muſt therefore correſpond to them; and ſince many of the objects or archetypes of ideas are diviſible, it neceſſarily follows, that the ideas themſelves are diviſible alſo; and hence he infers, that the ſentient principle in man, containing ideas which certainly have parts, and are diviſible, and conſequently having extenſion, cannot be that ſimple, indiviſible, and immaterial ſubſtance, that ſome have imagined it to be; but ſomething that has real extenſion, and therefore may have the other properties of matter. To this reaſoning an excellent writer replies, that it would be as proper to aſſert that ideas are hard or round, as to aſſert that they are diviſible. Perception is a ſingle and indiviſible act; and though the object perceived may be diviſible, the perception of it by the mind cannot be ſo. Dr. Prieſtley farther adds, that the ſoul poſſeſſes a great variety of mental affections, which neceſſarily imply alteration, eſpecially melioration and depravation, which is ſomething ſo ſimilar to corruption, that it has univerſally obtained the ſame name, and which is certainly incompatible with natural and perfect ſimplicity. This writer alleges alſo, in favour of the ſyſtem of materialiſm, that we hereby get rid of many difficulties, which muſt embarraſs the oppoſite ſyſtem; ſuch, *e. gr.* as theſe—what becomes of the ſoul during ſleep, in a ſwoon, when the body is ſeemingly dead (as by drowning, or other accidents), and eſpecially after death? alſo what was the condition of it before it became united to the body, and at what time did that union take place? what are the nature and ſtate of the ſouls of brutes? what is the uſe of the human body? &c. The ſyſtem of materialiſm, he ſays, which revelation uniformly ſuppoſes, is clogged with no difficulties of this kind. Man, according to this ſyſtem, is no more than what we now ſee of him. His being commences at the time of his conception, or perhaps at an earlier period. The corporeal and mental faculties, inhering in the ſame ſubſtance, grow, ripen, and decay together; and, whenever the ſyſtem is diſſolved, it continues in a ſtate of diſſolution, till it ſhall pleaſe that Almighty Being, who called it into exiſtence, to reſtore it to life again. Accordingly the Chriſtian ſyſtem provides no reward for the righteous till the general reſurrection of the juſt, nor any puniſhment for the wicked till the end of the world. Hence alſo the doctrine of the pre-exiſtence of human ſouls, and that of the pre-exiſtence of Chriſt, is rejected, as having no other foundation than the notion of there being ſomething in man quite different from his corporeal organized ſyſtem.

Dr. Prieſtley argues in many parts of his work on the ſuppoſition, that, according to the ideas of modern immaterialiſts, ſpirit can have no relation to place, and is incapable of being preſent any where. But Dr. Clarke, and ſome others of the beſt modern writers, did not entertain theſe ideas of ſpirit. Time and place are neceſſary to the exiſtence of all things; and hence Dr. Clarke infers, that infinite ſpace and duration are the eſſential properties of the Deity. Sir Iſaac Newton was alſo of the ſame opinion; and Dr. Price obſerves, that if ſpirit exiſts at all, it muſt exiſt ſomewhere, as well as in ſome time.

Dr. Prieſtley deduces another argument in favour of the material ſyſtem, from the conſideration, that ſpirit and body have no common property, and that it muſt, therefore, be impoſſible for them to act upon one another: againſt which it has been objected, that his principles tend to prove, that the Deity is material, as well as all inferior beings: and if matter be a power of attraction and repulſion united to extenſion, the Deity muſt be the ſame. But if this maxim be not univerſally true, and the Deity be immaterial, as Dr. Prieſtley himſelf aſſerts, it will follow, that ſpirit may act upon matter, without having any other common property with it than being locally preſent to it; and one of his chief arguments for the materiality of the ſoul will be given up. Beſides, allowing this maxim, how is it poſſible to avoid aſſerting the impoſſibility of the creation of the world out of nothing? For what common property can the Creator have with *nothing?* Dr. Prieſtley has laboured to prove, that the ſcriptures, both of the Old and New Teſtament, ſuppoſe and inculcate the doctrine of the uniform compoſition of man, or of the materiality of the human ſoul; and that, in conformity to this doctrine, the ſtate of retribution does not take place till after the general reſurrection. Accordingly, his ſyſtem leads him to deny the natural immortality of the ſoul, and its conſcious exiſtence in the intermediate ſtate. To thoſe who object, that if the ſoul be not naturally capable of ſurviving the body, or if death is unavoidably its deſtruction, then the reſurrection muſt be the reſurrection of a non-entity; he replies, that though the power of thinking cannot exiſt without its ſubſtance, which is an organized ſyſtem, yet if this property of thinking neceſſarily attends the property of life, nothing can be requiſite to the reſtoration of all the powers of the man, but the reſtoration of the body to a ſtate of life. And he apprehends that a reſurrection properly ſo called (becauſe this can be only a reſurrection of ſomething that had been dead, *viz.* the body), is manifeſtly uſeleſs, upon the ſuppoſition of there being a ſoul diſtinct from the body; it being, upon this hypotheſis, the ſoul, and not the body, that is the ſeat of all perception, and the ſource of all action. See SLEEP *of the Soul.*

Dr. Prieſtley conceives, that the three doctrines of materialiſm, of that which is commonly called Socinianiſm, and of philoſophical neceſſity, are equal parts of one ſyſtem, being equally founded on juſt obſervations of nature, and fair deductions from the ſcriptures; and that whoſoever ſhall duly conſider their connection and dependence on one another, will find no ſufficient conſiſtency in any general ſcheme of principles that does not comprehend them all. But it has been urged by another able writer, that if man be the matter itſelf which conſtitutes the man, and not its form or arrangement, as Dr. Prieſtley allows, the man will always remain while the matter which conſtitutes him remains, however different its organization or arrangement may be: that ſince death does not deſtroy the matter which conſtitutes man, it does not deſtroy the man; and that, conſequently, he goes on to exiſt after death, or is naturally immortal: that, in order to the reſurrection of the ſame man, the ſame matter muſt ariſe; and that it is no leſs poſſible for man to have exiſted *before* his birth, than it is, that he ſhould exiſt *after* his death; and that, conſequently, all the ſupport to the Socinian ſcheme, which Dr. Prieſtley derives from his ſentiments of materialiſm, falls to the ground. To this reaſoning, however, he replies, that the pre-exiſtence of the materials of the man Jeſus is a very different kind of pre-exiſtence from that of thoſe who make Chriſt, or rather the principal part of him, to have pre-exiſted in an active ſtate. We ſhall here ſubjoin the following argument, urged by the learned Dr. Clarke againſt Mr. Dodwell, in proof of the immateriality and natural immortality of the ſoul. That the ſoul cannot be material, he ſays, is demonſtrable from the ſingle conſideration even of bare ſenſe and conſciouſneſs itſelf. For matter being a diviſible ſubſtance, conſiſting always of ſeparable, nay, of actual ſeparate and diſtinct parts; it is plain, unleſs it were eſſentially conſcious, in which caſe every particle of matter muſt conſiſt of innumerable ſeparate and diſtinct conſciouſneſſes, no ſyſtem of it in any poſſible compoſition or diviſion, can be an individual conſcious being: for ſuppoſe three, or three hundred particles of matter, at a mile, or any given diſtance, one from another, is it poſſible that all thoſe ſeparate parts ſhould, in that ſtate, be one individual conſcious being? Suppoſe, then, all theſe particles brought together, into one ſyſtem, ſo as to touch one another, will they, thereby, or by any motion or compoſition whatſoever, become any whit leſs truly diſtinct beings than they were at the greateſt diſtance? How then can their being diſpoſed in any poſſible ſyſtem, make them one individual conſcious being? If you ſuppoſe God by his infinite power ſuperadding conſciouſneſs to the united particles, yet ſtill thoſe particles, being really and neceſſarily as diſtinct beings as ever, cannot be themſelves the ſubject in which that individual conſciouſneſs inheres; but the conſciouſneſs can only be ſuperadded by the addition of ſomething, which, in all the particles, muſt ſtill itſelf be but one individual being. The ſoul, therefore, whoſe power of thinking is undeniably one individual conſciouſneſs, cannot poſſibly be a material ſubſtance. See on the ſubject of this article, Brucker's Hiſtory of Philoſophy, by Enfield. Prieſtley's Diſquiſitions relating to Matter and Spirit, 8vo. 1777. Correſpondence between Dr. Price and Dr. Prieſtley, 8vo. 1778. Clarke's Demonſtration of the Being and Attributes of God. Anſwer to Dodwell. Controverſies with Collins; and Letters between him and Leibnitz. Butler's Analogy, chap. i. Baxter's Matho, vol. i. Enquiry into the Nature of the human Soul, &c. vol. i.

The notions of the ancients were very various with regard to the ſeat of the ſoul, and the mode of its action on the body. Some have maintained, that it is equally diffuſed through every part of it; and others ſay, that whilſt it influences and acts upon every part of the body, it has its principal reſidence in ſome particular part. Since it has been diſcovered, by the improvements in anatomy, that the nerves are the inſtruments of perception, and of the ſenſations accompanying it, and that the nerves ultimately terminate in the brain, it has been the general opinion of philoſophers that the brain is the ſeat of the ſoul; and that it perceives the images that are brought there, and external things, only by means of them. Des Cartes, obſerving that the PINEAL *Gland* (which ſee) is the only part of the brain that is ſingle, all the other parts being double, and thinking that the ſoul muſt have one ſeat, was thus determined to make that gland the ſoul's habitation; to which, by means of the animal ſpirits, intelligence is brought of all objects that affect the ſenſes. See CARTES and CARTESIANISM.

Others have not thought proper to confine the habitation of the ſoul to the pineal gland, but to the brain in general, or to ſome part of it, which they call the "ſenſorium." Even the great Newton favoured this opinion, though he propoſes it only as a query, with that modeſty which diſtinguiſhed him no leſs than his great genius.

"Is not," ſays he, "the ſenſorium of animals the place where the ſentient ſubſtance is preſent, and to which the ſenſible ſpecies of things are brought through the nerves and brain, that there they may be perceived by the mind preſent in that place? And is there not an incorporeal, living, intelligent, and omnipreſent Being, who, in infinite ſpace, as if it were in his ſenſorium, intimately perceives things themſelves, and comprehends them perfectly, as being preſent to them; of which things, that principle in us which perceives and thinks, diſcerns only in its little ſenſorium, the images brought to it through the organs of the ſenſes?" His great friend Dr. Clarke adopted the ſame ſentiments with more confidence. In his papers to Leibnitz, we find the following paſſages. "Without being preſent to the images of the things perceived, the ſoul could not poſſibly perceive them. A living ſubſtance can only there perceive when it is preſent, either to the things themſelves, (as the omnipreſent God is to the whole univerſe,) or to the images of things, (as the ſoul of man is in its proper ſenſory). Nothing can any more act, or be acted upon, where it is not preſent, than it can be where it is not. We are ſure the ſoul cannot perceive what it is not preſent to, becauſe nothing can act, or be acted upon, where it is not." See SENSORIUM.

Mr. Locke expreſſes himſelf in ſuch a manner, that, for the moſt part, one would imagine, that he thought the ideas, or images, of things, which he believed to be the immediate objects of perception, are impreſſions upon the mind itſelf; yet in ſome paſſages he rather places them in the brain, and makes them to be perceived by the mind there preſent. From ſuch paſſages, cited by Dr. Reid (ubi infra), it may be inferred, that he thought there are images of external objects conveyed to the brain. But whether he thought, with Des Cartes and Newton, that the images in the brain are perceived by the mind there preſent, or that they are imprinted on the mind itſelf, is not obvious. This hypotheſis is founded on three aſſumptions; and if any one of them fail, it muſt fall to the ground. 1. That the ſoul has its ſeat, or, as Mr. Locke calls it, its preſence-room, in the brain: 2. That images are formed in the brain of all the objects of ſenſe: 3. That the mind or ſoul perceives thoſe images in the brain; and that it perceives not external objects immediately, but only perceives them by means of thoſe images. The firſt aſſumption is not ſufficiently eſtabliſhed to warrant our founding other principles upon it. Of the ſecond there is no proof or probability, with regard to any of the objects of ſenſe. The brain has been diſſected times innumerable, by the niceſt anatomiſts; every part of it has been examined by the naked eye, and with the help of microſcopes; but no veſtige of any external object was ever found. The brain ſeems to be the moſt improper ſubſtance that can be imagined for receiving or retaining images, being a ſoft, moiſt, medullary ſubſtance. The third aſſumption is as improbable, as that there are images of external objects in the brain to be perceived. If our powers of perception, ſays Dr. Reid, be not altogether fallacious, the objects we perceive are not in our brain, but without us. Reid's Eſſay on the Intellectual Powers of Man, Eſſ. ii. ch. 4. See PERCEPTION.

Borri, a Milaneſe phyſician, in a letter to Bartholine, "De Ortu Cerebri, et Uſu Medico," aſſerts, that in the brain is found a very ſubtle fragrant juice, which is the principal ſeat or reſidence of the reaſonable ſoul; and adds, that the ſubtlety and fineneſs of the ſoul depends on the temperature of this liquor rather than on the ſtructure of the brain, to which it is uſually aſcribed. This liquor, we conceive, muſt be the ſame with what is uſually called the *nervous juice*, or *animal ſpirits:* the conſtitution of which is, doubtleſs, of great importance, with regard to the faculties of the ſoul.

Mr. Locke diſtinguiſhes two principal faculties or powers of the rational or human ſoul, *viz. perception* and *willing.* See POWER.

To theſe, other philoſophers add others; as *ſenſation, liberty, memory, imagination,* and *habit.*

The myſtic divines diſtinguiſh two principal parts of the ſoul: the *ſuperior part,* which comprehends the underſtanding and the will, and the *inferior part,* which comprehends imagination and ſenſation.

As to the ſoul of brutes, the Carteſians, and ſome others, deny its exiſtence in the common ſenſe of the word ſoul; that is, they ſtrip it of all the properties or faculties of the human ſoul: and the Peripatetics, on the contrary, inveſt it with the greateſt part, if not all of them.

In man, a particular agitation of the fibres of the brain is accompanied with a ſenſation of heat; and a certain flux of animal ſpirits towards the heart and viſcera is followed by love or hatred.

Now the Peripatetics maintain, that brutes feel the ſame heat, and the ſame paſſions, on the ſame occaſions; that they have the ſame averſion for what incommodes them; and, in the general, are capable of all the paſſions, and all the ſenſations we feel.

The Carteſians deny they have any perceptions or notices at all, that they feel any pain or pleaſure, or love or hate any thing. The ground of their opinion is, that they allow of nothing in brutes but what is material: and that they deny ſenſations and paſſions to be any properties of matter.

Some of the Peripatetics, on the other hand, maintain matter, when ſubtilized, framed, ranged, and moved, in a certain manner, to be capable of ſenſation and paſſion; that beaſts may feel and perceive, by means of the animal ſpirits, which are a matter thus modified; and that even the human ſoul itſelf only becomes capable of ſenſation and paſſion by means of it.

The maintainers of the contrary opinion urge that appearance of ſenſe, of fear, caution, love for their young, admirable ſagacity, both for their own preſervation and that of their ſpecies, viſible through the whole brute creation. And it is true, that all the actions of beaſts plainly expreſs an underſtanding, for every thing that is regular expreſſes it, even a machine or watch expreſſes it, and a plant much more; the radicle of the ſeed turning downwards, and the ſtem upwards, whatever ſituation the ſeed is ſown in; the young plant knitting from ſpace to ſpace to ſtrengthen it, its putting forth prickles, &c. to defend it, &c. mark a great underſtanding. All the motions of plants and brutes plainly diſcover an intelligence; but the intelligence does not reſide in the matter thereof; it is as diſtinct from the beaſt or plant, as that which ranged the wheels of the watch is diſtinct from the watch itſelf.

For, in effect, this intelligence appears infinitely great, infinitely wiſe, infinitely powerful; and the ſame which formed us in our mother's womb, which gave us our growth, &c. Thus, in brutes there is not either underſtanding or ſoul, in the ſenſe we generally uſe the word; they eat without pleaſure, cry without pain, grow without knowing it. They fear nothing, know nothing; and if they act in ſuch manner as ſhews underſtanding, it is becauſe God, having made them, to preſerve them, has formed their bodies ſo as to avoid whatever might hurt them mechanically.

Otherwiſe it might be ſaid, that there is more underſtanding in the vileſt inſect, nay, in the ſmalleſt grain, than in the moſt knowing men; for it is evident, either of them contains more parts, and produces more regular motions and actions, than we are capable of underſtanding. Thus does the great F. Malebranche argue againſt the ſouls of brutes. (Recherche de la Verité, liv. vi.) On this ſubject, ſee Brutes and Instinct.

In connection with the intereſting ſubject of this article, we ſhall here introduce ſome appropriate obſervations of an acute and elegant writer. (See Stewart's Elements of the Philoſophy of the Human Mind.) This writer agrees with Dr. Reid in ſuppoſing, that the notions we annex to the words matter and mind, are merely relative. If I am aſked, ſays he, what I mean by matter? I can only explain myſelf by ſaying, it is that which is extended, figured, coloured, moveable, hard or ſoft, rough or ſmooth, hot or cold; that is, I can define it in no other way, than by enumerating its ſenſible qualities. It is not matter or body which I perceive by my ſenſes; but only extenſion, figure, colour, and certain other qualities, which the conſtitution of my nature leads me to refer to ſomething which is extended, figured, and coloured. The caſe is preciſely ſimilar with reſpect to mind. We are not immediately conſcious of its exiſtence, but we are conſcious of ſenſation, thought, and volition; operations, which imply the exiſtence of ſomething which feels, thinks, and wills. Every man too is impreſſed with an irreſiſtible conviction, that all theſe ſenſations, thoughts, and volitions, belong to one and the ſame being; to that being which he calls *himſelf*; a being which he is led, by the conſtitution of his nature, to conſider as ſomething diſtinct from his body, and as not liable to be impaired by the loſs or mutilation of any of his organs. From theſe conſiderations it appears, that we have the ſame evidences for the exiſtence of mind, that we have for the exiſtence of body; nay, if there be any difference between the two caſes, that we have ſtronger evidence for it; inaſmuch as the one is ſuggeſted to us by the ſubjects of our conſciouſneſs, and the other merely by the objects of our perception. But as from our earlieſt years the attention is engroſſed with the qualities and love of matter, theſe phenomena occupy our thoughts more than thoſe of the mind, and we are perpetually tempted to explain the latter by the analogy of the former, and even to endeavour to refer them to the ſame general laws; and we acquire habits of inattention to the ſubjects of our conſciouſneſs, not eaſily ſurmounted. If, therefore, our notions of mind and matter are merely relative; if we know the one, only by ſuch ſenſible qualities as extenſion, figure, and ſolidity, and the other, by ſuch operations as ſenſation, thought, and volition, we are warranted in ſaying, that matter and mind, conſidered as objects of human ſtudy, are eſſentially different; the ſcience of the former reſting ultimately on the phenomena exhibited to our ſenſes, and that of the latter, on the phenomena of which we are conſcious. Inſtead, therefore, of objecting to the ſcheme of materialiſm, that its concluſions are falſe, it would be more accurate to ſay, that its aim is unphiloſophical. It proceeds on a miſapprehenſion of the proper object of ſcience; the difficulty which it profeſſes to remove being manifeſtly placed beyond the reach of our faculties. Surely, when we attempt to explain the nature of that principle which feels, and thinks, and wills, by ſaying, that it is a material ſubſtance, or that it is the reſult of material organization, we impoſe on ourſelves by words, forgetting that matter as well as mind is known to us by its qualities and attributes alone, and that we are totally ignorant of the eſſence of either. Should it be ſaid that the unknown ſubſtance which has the qualities of extenſion, figure, and colour, may be the ſame with the unknown ſubſtance which has the attributes of feeling, thinking, and willing; this is only an hypotheſis, which amounts to nothing more than a mere poſſibility; and even if it were true, it would no more be proper to ſay of mind that it is material, than to ſay of body that it is ſpiritual.

Souls, *Migration of*. See Migration and Metempsychosis.

Soul, *Sleep of the*. See Sleep *of the Soul*.

Soul-*Scot*, a certain fee paid by our Saxon anceſtors to the prieſt on opening a grave.

Soul's *Cheat*, a legacy anciently bequeathed at their deaths by our ſcrupulouſly pious anceſtors, to the pariſh-prieſt, to compenſate for any tithes that might have been forgot in their lives.

SOULAINES, in *Geography*, a town of France, in the department of the Aube, and chief place of a canton, in the diſtrict of Bar-ſur-Aube; 12 miles N. of Bar-ſur-Aube. The place contains 763, and the canton 7723 inhabitants, on a territory of 265 kiliometres, in 21 communes.

SOULAMEA, in *Botany*, ſlightly altered from *Soulamoe*, the name given to the plant in the iſland of Ternate. Lamarck Dict. v. 1. 449. Juſſ. 429. This is no other than what we have deſcribed under the article Rex Amaroris, to which we refer the reader. Commerſon, it ſeems, gathered this curious plant at Port Praſlin, in the Arſacides. Lamarck deſcribes the flowers with a three-cleft *calyx*, three *petals*, ſix *ſtamens*, and two *ſtigmas*. The *germen* is ſuperior.

Fruit an inverſely heart-ſhaped *capſule*, compreſſed, dilated at the margin, of two cells, each containing an oval *ſeed;* but it often happens that one of theſe ſeeds is abortive.

SOULANCOURT, in *Geography*, a town of France, in the department of the Upper Marne; 4 miles E. of Bourmont.

SOULE, a ſmall country of France, ſo called before the revolution, ſituated between Bearn and Navarre, of which Mauleon was the capital, now in the department of the Lower Pyrenées.

SOULLIERES, a town of France, in the department of Mont Blanc; 20 miles E. of St. Jean de Maurienne.

SOULONA, a town of Thibet; 20 miles E.S.E. of Coucour-Hotun.

SOULTZ, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the diſtrict of Colmar. The place contains 4298, and the canton 9317 inhabitants, on a territory of 87½ kiliometres, in 9 communes.

SOULZ-SOUS-FORETS, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the diſtrict of Wiſſembourg; 2 miles S. of Wiſſembourg. The place contains 1269, and the canton 13,768 inhabitants, on a territory of 145 kiliometres, in 26 communes.

SOUM, in *Agriculture*, a term denoting the paſturage of a full-grown cow. It is moſtly applied to lands in the moory ſtate, and ſuch as are under the ſheep-walk ſyſtem. It nearly anſwers, in ſome reſpects, to gaite. It is much uſed in the northern parts of Scotland. In the county of Perth, a horſe is accounted two ſoums; in ſome places four ſheep, but in other places five, are eſtimated at one ſoum; and of young cattle according to their age. The graſs of a ſoum, in hilly ground, is valued, on an average, from five to ſeven ſhillings, according to its quality. By ſome, much cenſure has been beſtowed on this mode of aſcertaining the value of paſture or graſs-land in the Highlands: but in mountainous diſtricts, where the ground has never been meaſured, and probably never will, where one mountain is exactly different from another in the quality and quantity of its produce as a paſture, and where there is even a great diverſity in different regions of the ſame mountain, it is perhaps not eaſy to conceive a better method of aſcertaining the value of paſture than by the number of cattle it can maintain. Whoever propoſes to explode any old cuſtom, ought, it is ſuppoſed, to ſubſtitute a better in its place.

Such old cuſtoms are now, however, a great deal more neglected and diſregarded, even in theſe Highland ſituations, than was formerly the caſe; juſt in the ſame manner as the term *gaite* has partially grown into diſuſe in different diſtricts in the ſouthern parts of the kingdom.

SOUMENZAC, in *Geography*, a town of France, in the department of the Lot and Garonne; 7 miles N.W. of Lauſun. N. lat. 44° 41′. E. long. 0° 27′.

SOUND, Sonus, a perception of the ſoul, communicated by means of the ear; or the effect of a colliſion of bodies, and a tremulous motion conſequent upon it, communicated thence to the circumambient fluid, and propagated through it to the organs of hearing.

Sound is not ſimply a vibration or undulation of the air, as ſome have called it, for there are many ſounds in which the air is not concerned, as when a tuning-fork or any other ſounding body is held by the teeth: nor is ſound always a vibration or alternation of any kind, for every noiſe is a ſound, and a noiſe, as diſtinguiſhed from a continued ſound, conſiſts of a ſingle impulſe in one direction only, ſometimes without any alternation; while a continued ſound is a ſucceſſion of ſuch impulſes, which, in the organ of hearing at leaſt, cannot but be alternate. If theſe ſucceſſive impulſes form a connected ſeries, following each other too rapidly to be ſeparately diſtinguiſhed, they conſtitute a continued ſound, like that of the voice in ſpeaking; and if they are equal among themſelves in duration, they produce a muſical or equable ſound, as that of a vibrating chord or ſtring, or of the voice in ſinging. Thus, a quill ſtriking againſt a piece of wood cauſes a noiſe, but ſtriking againſt the teeth of a wheel or comb, a continued ſound; and if the teeth of the wheel are at equal diſtances, and the velocity of the motion is conſtant, a muſical note.

To illuſtrate the cauſe of ſound, we obſerve, firſt, that a motion is neceſſary in the ſonorous body for the production of ſound. Secondly, that this motion exiſts, firſt, in the ſmall and inſenſible parts of the ſonorous bodies; and is excited in them by their mutual colliſion and percuſſion againſt each other, which produces that tremulous motion ſo obſervable in bodies that have a clear ſound, as bells, muſical chords or ſtrings, &c. Thirdly, that this motion is communicated to, or produces a like motion, uſually in the air, or ſuch parts of any material ſubſtance as are fit to receive and propagate it, inaſmuch as no motion of bodies, at a diſtance, can affect our ſenſes, without the mediation of other bodies, which receive thoſe motions from the ſonorous body, and communicate them immediately to the organ. Laſtly, that this motion muſt be communicated to thoſe parts that are the proper and immediate inſtruments of hearing. See Ear.

Further, that motion of a ſonorous body which is the immediate cauſe of ſound, may be owing to two different cauſes: either the percuſſion between it and other hard bodies, as in drums, bells, ſtrings, &c. or the beating and daſhing of the ſonorous body and the air immediately againſt each other, as in wind-inſtruments, flutes, trumpets, &c.

But, in both caſes, the motion, which is the conſequence of the mutual action, and the immediate cauſe of the ſonorous motion which the air conveys to the ear, is an inviſible, tremulous, or undulating motion, in the ſmall and inſenſible parts of the body.

To explain this, all ſenſible bodies are ſuppoſed to conſiſt of a number of ſmall and inſenſible parts or corpuſcles, which are of the ſame nature in all bodies, and are perfectly hard and incompreſſible.

Of theſe are compoſed others, ſomewhat greater, but ſtill inſenſible; and theſe different, according to the different figures and union of their component parts. Theſe, again, conſtitute other maſſes, bigger and more different than the former; and of the various combinations of theſe laſt, are thoſe groſs bodies compoſed that are viſible, tangible, &c. The firſt and ſmalleſt parts, we have obſerved, are abſolutely hard; the others are compreſſible, and are united in ſuch manner, that, being compreſſed by an external impulſe, they have an elaſtic or reſtitutive power, by which they reſtore themſelves to their natural ſtate.

A ſhock, then, being made by one body upon another, the ſmall particles, by their elaſtic principle, move to and again with a very great velocity, in a tremulous, undulating manner, ſomewhat like the viſible motions of groſſer ſprings; as we eaſily obſerve in the ſtrings of muſical inſtruments. And this is what we may call the *ſonorous motion*, which is propagated to the ear; but obſerve, that it is the inſenſible motion of thoſe particles next the ſmalleſt, which is ſuppoſed to be the immediate cauſe of ſound; and, of theſe, only thoſe next the ſurface communicate with the air, the motion of the whole, or of the greater parts, being no farther concerned, than as they contribute to the other.

To apply this theory, ſtrike a bell with any hard body, and you eaſily perceive a ſenſible tremor on the ſurface, ſpreading itſelf over the whole, and that more ſenſibly as the ſhock is greater. Upon touching it in any other part, the motion and the ſound too are ſtopped. Now this is apparently a motion of the ſmall and inſenſible parts, changing their ſituation, with reſpect to one another; which being ſo many, and ſo cloſely united, we cannot perceive their motions ſeparately and diſtinctly; but only a trembling, which we reckon to be the effect of the confuſion of an infinite number of little particles, cloſely joined, and only moving in infinitely little lines.

M. Perrault adds, that the viſible motion of the parts contributes no otherwiſe to ſound, than as it cauſes the inviſible motion of the ſmaller parts, which he calls *particles*, to diſtinguiſh them from the ſenſible ones, which he calls *parts*, and from the ſmalleſt of all, which we call *corpuſcles*.

This he ſupports from the inſtance of a chord or ſtring, which being ſtruck, and the ſound, and ſenſible undulations, at reſt again, if you approach the chord ſoftly with the finger, you will find a ſmall tremulous motion, which is the remains of the vibrations of the whole ſtring and the parts. Now the parts vibrate without any ſound; but no ſooner is the vibration felt by the finger, than the ſound is heard again; which he aſcribes to this, that the motion of the parts being inſufficient to move the particles, whoſe motion is the firſt that ceaſes, requires ſome aſſiſtance from daſhing againſt the finger, whereby to become enabled to give the particle the motion neceſſary for the producing of ſound. He finiſhes his proof by the inſtance of flutes, which, when made of different matters, as wood, metal, &c. whoſe parts are very different, but their particles nearly the ſame, if their lengths and bore be the ſame, there is very little ſenſible difference in their ſounds.

The ſonorous body having made its impreſſion on the contiguous air, that impreſſion is propagated from one particle to another, according to the laws of pneumatics.

A few particles, for inſtance, driven from the ſurface of the body, drive their neighbouring particles into a leſs ſpace; and the medium, as it is thus rarefied in one place, becomes condenſed in the other; but the air, thus compreſſed in the ſecond place, is, by its elaſticity, returned back again, both to its former place and its former ſtate; and the air contiguous to that is compreſſed; and the like obtains, when the air leſs compreſſed expanding itſelf, a new compreſſion is generated. From each agitation of the air, therefore, there ariſes a motion of the air, analogous to the motion of a wave on the ſurface of the water; which we call a *wave*, or *undulation* of air.

In each wave the particles go and return back again, through very ſhort, but equal ſpaces; the motion of each particle is analogous to the motion of a vibrating pendulum, while it performs two oſcillations; and moſt of the laws of the pendulum, with very little alteration, are applicable thereto.

The only condition neceſſary for the production of a ſimple ſound, is a ſufficient degree of velocity in the motion or impulſe which occaſions it. A very moderate velocity muſt be ſufficient for producing an impreſſion on the ear: and when the ſound is continued, it may remain audible with a velocity of no more than one hundredth part of an inch in a ſecond, or perhaps with a velocity much leſs than this; but at its origin, it is probable that the velocity of the motion conſtituting a ſound muſt always be conſiderably greater. A continued ſound may be produced by a repetition of ſeparate impulſes, independent of each other, as when a wheel ſtrikes in rapid ſucceſſion the teeth of a pinion, ſo as to force out a portion of air from between them; when a pipe, through which air is paſſing, is alternately opened and ſhut, either wholly or partially, by the revolution of a ſtop-cock or valve; or when a number of parallel ſurfaces is placed at equal diſtances, in a line nearly perpendicular to them, and a noiſe of any kind is reflected from each of them in ſucceſſion:—a circumſtance which may often be obſerved, when we are walking near an iron railing, an acute ſound being heard, which is compoſed of ſuch reflections from the ſurfaces of the paliſades. See Sound, in *Muſic*, *infra*.

Sounds are as various as are the means that concur to their production. The principal varieties reſult from the figure, conſtitution, quantity, &c. of the ſonorous body; the manner of percuſſion, with the velocity, &c. of the vibrations conſequent thereon; the ſtate and conſtitution of the medium; the diſpoſition, diſtance, &c. of the organ; the obſtacles between the organ and the ſonorous object, and the adjacent bodies. The moſt notable diſtinction of ſounds, ariſing from the various degrees and combinations of the conditions mentioned, are into *loud* and *low* (or ſtrong and weak); into *grave* and *acute* (or ſharp and flat, or high and low); and into *long* and *ſhort*: the management of which makes the office of muſic. See the next article.

M. Euler is of opinion, that no ſound, making fewer vibrations than 30, or more than 7520 in a ſecond, is diſtinguiſhable by the human ear. According to this doctrine, the limit of our hearing, as to acute and grave, is an interval of eight octaves. Tentam. Nov. Theor. Muſ. cap. i. ſect. 13.

The velocity of ſound is the ſame with that of the aerial waves, and does not differ much, whether it go with the wind or againſt it. By the wind, indeed, a certain quantity of air is carried from one place to another; and the ſound is accelerated, while its waves move through that part of the air, if their direction be the ſame as that of the wind. But as ſound moves much more ſwiftly than wind, the acceleration it will hereby receive is inconſiderable; and the chief effect we can perceive from the wind is, that it increaſes and diminiſhes the ſpace of the waves, ſo that by help of it the ſound may be heard to a greater diſtance than otherwiſe it would. See Wind, & *infra*.

That the air is the ordinary medium of ſound, and that the preſence of this, or of ſome other material ſubſtance for its tranſmiſſion is neceſſary, appears from various experiments in rarefied and condenſed air. In an unexhauſted receiver, a ſmall bell may be heard at ſome diſtance; but when exhauſted, it can ſcarcely be heard at the ſmalleſt diſtance. If the air be condenſed, the ſound will be louder proportionably to the condenſation, or quantity of air crowded in, of which we have many inſtances in Mr. Haukſbee's experiments. From theſe experiments (Phil. Tranſ. 1709, xxiv. 1902, 1709, xxvi. 367. 371.) it appears, that a bell was heard at the diſtance of 30 yards, when the air was in its common ſtate, at 60 with the force of two atmoſpheres, at 90 with the force of three: beyond this the intenſity did not much increaſe.

Beſides, ſounding bodies communicate tremors to diſtant bodies; *e. g.* the vibrating motion of a muſical ſtring puts others in motion, whoſe tenſion and quantity of matter diſpoſe their vibrations to keep time with the pulſes of air, propagated from the ſtring that was ſtruck. Galileo explains this phenomenon by obſerving, that a heavy pendulum may be put in motion by the leaſt breath of the mouth, provided the blaſts be often repeated, and keep time exactly with the vibrations of the pendulum, and alſo by the like art in raiſing a large bell.

Dr. Prieſtley conſtructed an apparatus in order to aſcertain whether the intenſity of ſound is affected by any other property of the air in which it is made beſides its mere denſity. The reſult of his experiments with different kinds of air was, that the intenſity of ſound depends ſolely upon the denſity of the air in which it is made, and not at all upon any chemical principle in its conſtitution. In inflammable air the ſound of the bell he uſed was hardly to be diſtinguiſhed from the ſame in a pretty good vacuum ; and this air is ten times rarer than common air. In fixed air the ſound was much louder than in common air, ſo as to be heard about half as far again ; and this air is in about the ſame proportion, denſer than common air. In dephlogiſticated air the ſound was alſo ſenſibly louder than in common air. Experiments and Obſervations, &c. vol. v. p. 296, &c.

But it is not the air alone that is capable of the impreſſions of ſound, but water alſo, as is manifeſt by ſtriking a bell under water, the ſound of which may plainly enough be heard, only not ſo loud, and alſo a fourth deeper, according to good judges in muſical notes. And Merſenne ſays, a ſound made under water is of the ſame tone or note as if made in air, and heard under water.

It does not appear that any direct experiments have been made on the velocity with which an impulſe is tranſmitted through a liquid, although it is well known that liquids are capable of conveying ſound without difficulty. Profeſſor Robiſon informs us, that he heard the ſound of a bell tranſmitted by water, at the diſtance of 1200 feet. It is eaſy to calculate the velocity with which ſound muſt be propagated in any liquid, of which the compreſſibility has been meaſured. Mr. Canton has aſcertained, that the elaſticity of water is about 22,000 times as great as that of air : it is, therefore, meaſured by the height of a column, which is in the ſame proportion to 34 feet, that is 750,000 feet ; and the velocity correſponding to half this height is 4900 feet in a ſecond. In mercury alſo, it appears from Mr. Canton's experiments, that the velocity muſt be nearly the ſame as in water ; in ſpirit of wine a little ſmaller. The experiments were made by filling the bulb of a thermometer with water, and obſerving the effects of placing it in an exhauſted receiver, and in condenſed air ; taking care to avoid changes of temperature, and other ſources of error. The fluid roſe in the tube when the preſſure was removed, and ſubſided when it was increaſed. A ſlight correction, however, is neceſſary, on account of the expanſion and contraction of the glaſs, which muſt have tended to make the elaſticity of the fluids appear ſomewhat greater than it really was. See COMPRESSION.

The leaſt elaſtic ſubſtance that has been examined is perhaps carbonic acid gas, or fixed air, which is conſiderably denſer than atmoſpherical air, expoſed to an equal degree of preſſure. The height of the atmoſphere, ſuppoſed to be homogeneous, is, in ordinary circumſtances, and at the ſea-ſide, about 28,000 feet ; and in falling through half this height, a heavy body would acquire a velocity of 946 feet in a ſecond. But from a compariſon of the accurate experiments of Derham, made in the day-time, with thoſe of the French academicians, made chiefly at night, the true velocity of ſound is about 1130 feet in a ſecond ; which agrees very nearly with ſome obſervations made with great care by profeſſor Pictet. This difference between calculation and experiment, which has long occupied the attention of natural philoſophers, has been in a great meaſure removed by the ſuggeſtion of La Place, who has attributed the effect to the elevation of temperature, which is always found to accompany the action of condenſation, and to the depreſſion produced by rarefaction. When the denſity of the air is changed, while its elaſticity remains unaltered, which happens when it is expanded by heat, or condenſed by cold, the height of the column, and conſequently the velocity, will alſo be altered ; ſo that for each degree of Fahrenheit's thermometer, the velocity will vary about one part in a thouſand. Bianconi has actually obſerved this difference of velocity according to the different heights of the thermometer, and it may be ſhewn leſs directly by means of the ſounds of pipes ; but it has not been accurately determined whether or not the correction, on account of the effect of compreſſion in cauſing heat, remains unaltered, although Bianconi's experiments agree very well with the ſuppoſition that no material change takes place in this reſpect. The velocity of ſound muſt alſo be, in ſome meaſure, influenced by the quantity of moiſture contained in the atmoſphere : it muſt be a little diminiſhed by cold fogs, which add to the denſity, without augmenting the elaſticity ; and increaſed by warm vapours, which tend to make the air lighter : and theſe two oppoſite ſtates are probably often produced in ſucceſſion, in wind inſtruments blown by the mouth ; the air within them being at firſt cold and damp, and afterwards warm and moiſt.

In pure hydrogen gas, the velocity of ſound ought, from calculation, to be more than three times as great as in common air ; but the difference does not appear to have been ſo great in any experiment hitherto made on the ſounds of pipes, in gaſes of different kinds. For ſuch experiments, the comparative ſpecific gravity of the gas may be moſt conveniently aſcertained by Mr. Leſlie's method of obſerving the time employed in emptying a veſſel through a ſmall orifice, by means of the preſſure of an equal column of water ; according to the ſimple theory, the velocities of the gas thus diſcharged ought to be in the ſame proportion as the reſpective velocities with which ſounds would be tranſmitted by them : and if any variation from this proportion were diſcovered, it muſt be attributed to the different degrees of heat produced by condenſation in the different fluids. Steam, at the temperature of boiling water, is only one-third as heavy as common air ; conſequently the velocity of ſound in ſteam muſt be nearly three-fourths greater than in air.

A certain time is always required for the tranſmiſſion of an impulſe through a material ſubſtance, even through ſuch ſubſtances as appear to be the hardeſt, and the leaſt compreſſible. It is demonſtrable that all minute impulſes are conveyed through any homogeneous elaſtic medium, whether ſolid or fluid, with an uniform velocity, which is always equal to that which a heavy body would acquire by falling through half the height of the modulus of elaſticity, that is, in the caſe of the air, half the height of the atmoſphere, ſuppoſed to be of equal denſity ; ſo that the velocity of ſound, paſſing through an atmoſphere of an uniform elaſtic fluid, muſt be the ſame with that of a wave moving on its ſurface. In order to form a diſtinct idea of the manner in which ſound is propagated through an elaſtic ſubſtance, we muſt firſt conſider the motion of a ſingle particle, which, in the caſe of a noiſe, is puſhed forwards, and then either remains ſtationary, or returns back to its original ſituation ; but, in the caſe of a muſical ſound, is continually moved backwards and forwards, with a velocity always varying, and varying by different degrees, according to the nature or quality of the tone : for inſtance, differently in the notes of a bell and of a trumpet. We may firſt ſuppoſe, for the ſake of ſimplicity, a ſingle ſeries of particles to be placed only in the ſame line with the direction of the motion. It is obvious, that if theſe particles were abſolutely incompreſſible, or infinitely elaſtic, and were alſo retained in contact with each other by an infinite force of coheſion or of compreſſion, the whole ſeries muſt move preciſely at the ſame time, as well as in the ſame manner. But in a ſubſtance which is both compreſſible and extenſible or expanſible, the motion muſt occupy a certain time in being propagated to the ſucceſſive particles on either ſide, by means of the impulſe of the firſt particle on thoſe which are before it, and by means of the diminution of its preſſure on thoſe which are behind; ſo that when the ſound conſiſts of a ſeries of alternations, the motion of ſome of the particles will be always in a leſs advanced ſtate than that of others nearer to its ſource; while at a greater diſtance forwards, the particles will be in the oppoſite ſtage of the undulation; and ſtill further on, they will again be moving in the ſame manner with the firſt particle, in conſequence of the effect of a former vibration.

It is well known, that ſolid bodies in general are good conductors of ſound: thus, any agitation communicated to one end of a beam is readily conveyed to the ear, applied to the other end of it. The motion of a troop of cavalry is ſaid to be perceived at a greater diſtance, by liſtening with the head in contact with the ground, than by attending to the ſound conveyed through the air; and we may frequently obſerve, that ſome parts of the furniture of a houſe are a little agitated by the approach of a waggon, before we hear the noiſe which it immediately occaſions. The velocity, with which impulſes are tranſmitted by ſolids, is in general conſiderably greater than that with which they are conveyed by the air. Mr. Wunſch has aſcertained this by direct obſervations on a ſeries of deal rods cloſely united together, which appeared to tranſmit a ſound inſtantaneouſly, while a ſenſible interval was required for its paſſing through the air. He alſo found that the blow of a hammer on a wall, at the upper part of a high houſe, is heard as if double by a perſon ſtanding near it on the ground; the firſt ſound deſcending through the wall, the ſecond through the air. It appears from experiments on the flexure of ſolid bodies of all kinds, that their elaſticity, compared with their denſity, is much greater than that of the air: thus, the height of the modulus of elaſticity of fir wood is found, by means of ſuch experiments, to be about 9,500,000 feet; whence the velocity of an impulſe conveyed through it muſt be 17,400 feet, or more than three miles, in a ſecond. It is obvious, therefore, that in all common experiments, ſuch a tranſmiſſion muſt appear perfectly inſtantaneous. There are various methods of aſcertaining this velocity from the ſounds produced under different circumſtances, by the ſubſtances to be examined; and profeſſor Chladni has, in this manner, compared the properties of a variety of natural and artificial productions.

Sound may be propagated not only in ſingle right lines, or in parallel lines, but uſually the impulſe that occaſions it, more eſpecially when ſound is tranſmitted through a fluid, ſpreads in every direction, ſo as to occupy at any one time nearly the whole of a ſpherical ſurface. It is impoſſible, however, that the whole of this ſurface ſhould be affected in a ſimilar manner by any ſound, originating from a vibration confined to a certain direction, ſince the particles behind the ſounding body muſt be moving towards the centre, whenever the particles before it are retreating from the centre; ſo that in one half of the ſurface, the motions may be called retrograde or negative, while in the other they are direct or poſitive: conſequently at the ſides, where theſe portions join, the motions can neither be poſitive nor negative, and the particles muſt remain at reſt: the motions muſt alſo become gradually leſs and leſs ſenſible, as they approach to the limit between the two hemiſpheres. This ſtatement may be confirmed by an experiment on the vibration of a body, of which the motion is limited to a certain direction; the ſound being ſcarcely audible, when the ear is in a direction preciſely perpendicular to that of the vibration. The ſound, thus diverging, muſt always be ſpread through a part of a ſpherical ſurface, becauſe its velocity muſt be equal in every direction; ſo that the impulſe will always move forwards in a ſtraight line paſſing through the centre of the ſphere, or the vibrating body. But when a hemiſpherical pulſe arrives at the ſurface of a plane ſolid obſtacle, it is reflected, preciſely in the ſame manner that a wave of water is reflected, and aſſumes the form of a pulſe proceeding from a centre at an equal diſtance on the oppoſite ſide of the ſurface. This reflection, when it returns back perpendicularly, conſtitutes what is commonly called an *echo* (which ſee): but in order that the echo may be heard diſtinctly, it is neceſſary that the reflecting object be at a diſtance moderately great, otherwiſe the returning ſound will be confuſed with the original one; and it muſt either have a ſmooth ſurface, or conſiſt of a number of ſurfaces arranged in a ſuitable form: thus there is an echo not only from a diſtant wall or rock, but frequently from the trees in a wood, and ſometimes, as it is ſaid, even from a cloud.

If a ſound or a wave be reflected from a curved ſurface, the new direction which it will aſſume may be determined, either from the condition that the velocity with which the impulſe is tranſmitted muſt remain unaltered, or from the law of reflection, which requires that the direction of the reflected pulſe or wave be ſuch as to form an angle with the ſurface, equal to that which the incident pulſe before formed with it. Thus, if a ſound or wave proceed from one focus of an ellipſe, and be reflected at its circumference, it will be directed from every part of the circumference towards the other focus; ſince the diſtance which every portion of the pulſe has to paſs over in the ſame time, in following this path, is the ſame, the ſum of the lines drawn from the foci to any part of the curve being the ſame; and it may alſo be demonſtrated that theſe lines form always equal angles with the curve on each ſide. (See ELLIPSE.) If an ellipſe be prolonged without limit, it will become a *parabola* (which ſee); hence a parabola is the proper form of the ſection of a tube, calculated for collecting a ſound which proceeds from a great diſtance into a ſingle point, or for conveying a ſound nearly in parallel directions to a very diſtant place. It appears, therefore, that a parabolic conoid is the beſt form for a hearing trumpet, and for a ſpeaking trumpet. See TRUMPET.

The decay of ſound is the natural conſequence of its diſtribution throughout a larger and larger quantity of matter, as it proceeds to diverge every way from its centre. The actual velocity of the particles of the medium tranſmitting it appears to diminiſh ſimply in the ſame proportion as the diſtance from the centre increaſes; conſequently their energy, which is to be conſidered as the meaſure of the ſtrength of ſound, muſt vary as the ſquare of the diſtance; ſo that, at the diſtance of ten feet from the ſounding body, the velocity of the particles of the medium becomes one-tenth as great as at the diſtance of one foot; and their energy, or the ſtrength of the ſound, only one-hundredth as great. Young's Lect. on Nat. Phil. vol. i. lect. 31.

The ſpace through which ſound is propagated, in a given time, has been very differently eſtimated by authors who have written concerning this ſubject. Roberval gives it at the rate of 560 feet in a ſecond; Gaſſendus, at 1473; Merſenne, at 1474; Du Hamel, in the Hiſtory of the Academy of Sciences at Paris, at 1172; the Academy del Cimento, at 1148; Boyle, at 1200; Roberts, at 1300; Walker, at 1338; ſir Iſaac Newton, at 968; Dr. Derham, in whoſe meaſure Mr. Flamſteed and Dr. Halley acquieſced, at 1142.

The reaſon of which variety Dr. Derham aſcribes partly to ſome of thoſe gentlemen uſing ſtrings and plummets, inſtead of regular pendulums; and partly to there not being diſtance enough between the ſonorous body and the place of obſervation; and partly to there being no regard had to the winds: Derham having found the effects of the wind, though not of any changes of weather.

But by the accounts ſince publiſhed by M. Caſſini de Thury, in the Memoirs of the Royal Academy of Sciences at Paris for the year 1738, where cannon were fired at various as well as great diſtances, under great variety of weather, wind, and other circumſtances, and where the meaſures of the different places had been ſettled with the utmoſt exactneſs, ſound was propagated at a medium at the rate only of 1038 French feet in a ſecond. The French foot exceeds the Engliſh by nearly ſeven lines and a half, or is as 107 to 114; and conſequently 1038 French feet are equal to 1106 or 1107 Engliſh feet. The difference, therefore, of the meaſures of Dr. Derham and M. Caſſini is 34 French, or 36 Engliſh feet, in a ſecond. According to this laſt meaſure, the velocity of ſound, when the wind is ſtill, is ſettled at the rate of a mile, or 5280 Engliſh feet in $4\frac{77}{100}''$.

According to Mayer, the velocity of ſound in a ſecond is 1105 feet; according to Müller, 1109; and according to Pictet, about 1180. According to Bianconi (C. Bon. ii. i. 365.), in ſummer, the thermometer being at 20°, 70 vibrations of the pendulum elapſed while a ſound paſſed over 13 miles; in winter, 79 ſeconds, the thermometer being at 1.2°. In a cloud or miſt, $155''$ elapſed while the ſound paſſed and repaſſed. Hence the air ſhould expand $\frac{6}{76}$ for 21.2°, or $\frac{1}{270}$ for 1° of the thermometer employed, probably Reaumur's, which is $\frac{1}{608}$ for 1° of Fahrenheit. The mean difference of the temperature of the air was probably ſomewhat leſs than is ſuppoſed, perhaps 17° or 18°.

Chladni infers, from the longitudinal vibrations of different ſubſtances, a velocity of 7800 feet in a ſecond in tin, 9300 in ſilver, 12,500 in copper, 17,500 in glaſs and iron, 11,000 to 18,000 in wood, and 10,000 to 12,000 in tobacco-pipes. Theſe obſervations are fully confirmed from different grounds. According to the elaſticity of fir, as inferred from an experiment of Mr. Leſlie, the velocity of an impulſe ſhould be 17,300. The velocity may be eaſily calculated from the ſound of a braſs-rod: if the number of vibrations of the graveſt ſound in a ſecond be n, the velocity will be $978\,\frac{n\,l^2}{d}$, l being the length, and d the depth in feet. From an experiment of this kind, Dr. Young ſays (Lect. on Phil. vol. ii. p. 266.) that he found the velocity 17,700 in crown glaſs, and 11,800 in braſs.

Some of the moſt conſiderable queries, relating to the laws of ſounds, have been propoſed by Dr. Derham; and he anſwered ſeveral of them accurately, from experiments made for that purpoſe by himſelf, as follows:

How far does a ſound move in a ſecond of time? Sound moves 1142 feet, or 380 yards in a ſecond, which is juſt an Engliſh mile in $9\frac{1}{4}$ or 9.25 half ſeconds; two miles in $18\frac{1}{2}$; three miles, or a league, in $27\frac{3}{4}$, &c.; and about 13 miles in one minute.

But ſea-miles are to land-miles nearly as 7 to 6; and, therefore, ſound runs a ſea-league in about 12 ſeconds of time. It is a common obſervation, that perſons in good health have about 75 pulſations, or beats, of the artery at the wriſt, in a minute; conſequently, in 75 pulſations, ſound flies about 13 land-miles, and about $11\frac{1}{7}$ ſea-miles, which is about one land-mile in ſix pulſes, and about one ſea-mile in near ſeven pulſes, or a league in 20 pulſes. And hence the diſtance of objects may be found, by knowing the time which ſound takes to move from thoſe objects to an obſerver. *E. g.* upon ſeeing the flaſh of a gun at ſea, if 56 beats of the pulſe at the wriſt were counted before the report was heard, the diſtance of that gun may be eaſily found by dividing 56 by 20, which gives 2.8 leagues, or about eight miles.

Does the report of a gun, diſcharged with its mouth towards us, come ſooner than when the muzzle is from the obſerver? By repeated experiments it appears, there is no difference in the ſound from this different direction.

Do ſounds move in the ſame time, through the ſame ſpaces, in all ſtates of the atmoſphere, and heights of the barometer, by day and by night, in ſummer and in winter, in ſnowy and in clear weather, in this or that climate? By repeated experiments, it does not appear there ariſes any difference from any of theſe different circumſtances.

Do the winds affect the motion of ſounds? By repeated experiments, it appears, there is ſome, though a very ſmall difference, in the velocity of ſounds, with or againſt the wind; which is alſo augmented or diminiſhed by the ſtrength or weakneſs of the wind.

Do a great and intenſe ſound, and a ſmall or languid one, move with the ſame velocity? It appears that they do.

For by experiments, a cannon fired with a half-pound charge of powder, was heard at about the diſtance of $17\frac{1}{2}$ miles, in the ſame time after the flaſh was ſeen, as when fired with a charge of ſix pounds.

Does the ſound of a gun move equally ſwift at all elevations of the gun? It does.

Do different quantities or ſtrengths of gunpowder occaſion any difference as to the velocity of the ſound? None.

Does ſound move in a right line the neareſt way, or does it ſweep along the earth's ſurface? And is there any difference in the time, if the piece be diſcharged in an acclive and a declive poſition? Sound moves the neareſt way; and the velocity appears to be the ſame in acclivities as in declivities.

Have all kinds of ſounds, as thoſe of guns, bells, &c. the ſame velocity? And are ſounds equally ſwift in the beginning of their motion and in the end? There appears no inequality in either of theſe reſpects; and, therefore, the times in which ſound is heard are proportional to the diſtance; that is, at a double diſtance it is heard in twice the time, &c.

Sound, *for the Reflection, Refraction, &c. of.* See Echo and Phonics.

Sounds, *Articulate.* See Articulate.

Sound, in *Muſic*, denotes a quality in the ſeveral agitations of the air, conſidered as their diſpoſition, meaſure, &c. may make muſic or harmony.

Muſical ſounds are moſt frequently produced by the alternate motions of ſubſtances naturally capable of iſochronous vibrations; which ſubſtances may be either ſolids or fluids, or inſtruments compoſed of a combination of fluids with ſolids. The reſonance of a room or paſſage is one of the

Printed by A. Strahan,

the ſimpleſt ſources of a muſical ſound; the walls being parallel, the impulſe is reflected backwards and forwards continually, at equal intervals of time, ſo as to produce the effect of a muſical ſound. When we blow obliquely and uniformly into a cylindrical pipe cloſed at one end, the impulſe or condenſation muſt probably travel to the bottom and back, before the reſiſtance is increaſed; the current of our breath will then be diverted from the mouth of the pipe, for an equal time, which will be required for the diminution of the reſiſtance by the diſcharge of the condenſed air, ſo that the whole time of a vibration will be equal to the time occupied by an impulſe of any kind in paſſing through four times the length of the pipe. An open pipe may be conſidered nearly as if it conſiſted of two ſuch pipes, united at their cloſed ends; the portions of air contained by them being agitated by contrary motions, ſo as always to afford each other a reſiſtance ſimilar to that which the bottom of the ſtopped pipe would have furniſhed. It is probable, ſays Dr. Young, that when an open pipe is once filled with air a little condenſed, the oblique current is diverted, until the effect of the diſcharge, beginning at the remoter end, has returned to the inflated orifice, and allowed the current to re-enter the pipe. Where the diameter of the pipe is different at different parts of its length, the inveſtigation of the ſound becomes much more intricate; but it has been purſued by M. Daniel Bernouilli with conſiderable ſucceſs, although upon ſuppoſitions, ſays Young, not ſtrictly conſiſtent with the actual ſtate of the motions concerned.

In the ſame manner as an open pipe is divided by an imaginary baſis, ſo as to produce the ſame ſound with a ſtopped pipe of half the length, a pipe of any kind is capable of being ſubdivided into any number of ſuch pipes, ſuppoſed to meet each other's correſponding ends only; and in general the more violently the pipe is inflated, the greater is the number of parts into which it ſubdivides itſelf, the frequency of the vibrations being always proportional to that number. Thus, an open pipe may be divided not only into two, but alſo into four, ſix, eight, or more portions, producing the ſame ſounds as a pipe of one-half, one-third, one-fourth, or any other aliquot part of the length; but a ſtopped pipe cannot be divided into any even number of ſimilar parts; its ſecondary ſounds being only thoſe of a pipe of which the proportion is determined by the odd numbers, its length being, for example, one-third, one-fifth, or one-ſeventh of the original length. Theſe ſecondary notes are ſometimes called harmonics; they are not only produced in ſucceſſion from the ſame pipe, but they are alſo often faintly heard together, while the fundamental note of the pipe continues to ſound. When the pipe has a large cavity connected with it, or conſiſts principally of ſuch a cavity, with a ſmall opening, its vibrations are uſually much leſs frequent, and it is generally incapable of producing a regular ſeries of harmonics.

It is obvious, from this ſtatement of the analogy between the velocity of ſound and the vibrations of the air in pipes, that they muſt be affected in a ſimilar manner by all alterations of temperature. Thus, the frequency of the vibrations of a pipe muſt be increaſed nearly in the ratio of 33 to 34 by an elevation of 30 degrees of Fahrenheit's thermometer; and if this change be accompanied by a tranſition from dampneſs to ſimple moiſture, the ſound will be ſtill more altered.

Dr. Chladni has diſcovered that ſolids of all kinds, when of a proper form, are capable of longitudinal vibrations, exactly reſembling in their nature thoſe of the air in an organ-pipe, having alſo their ſecondary or harmonic notes related to them in a ſimilar manner. Theſe vibrations are always far more frequent than thoſe of a column of air of equal length, the velocity with which an impulſe is tranſmitted by a ſolid of any kind, being uſually from 5 to 16 times as great as the velocity of ſound in air; ſo that the longitudinal ſounds are always extremely acute, when they are produced by ſubſtances of moderate length. Theſe ſounds afford perhaps the moſt accurate mode of determining the velocity of the tranſmiſſion of an impulſe through any elaſtic ſubſtance, and of obtaining from that velocity the exact meaſure of its elaſticity: they may be eaſily exhibited by holding a long bar or wire of iron or braſs in the middle, and ſtriking it at one end with a ſmall hammer in the direction of its length.

The vibrations by which ſolid bodies moſt uſually produce ſound, are, however, not longitudinal, but lateral, and they are governed either by a tenſion, derived from the operation of a weight, or of ſome other external force, or by the natural elaſticity of the ſubſtance. The vibrations of extended ſubſtances reſemble moſt in their properties thoſe of elaſtic fluids, and they occur the moſt frequently in practice, although the vibrations produced by the elaſticity of the ſubſtance may be conſidered as the moſt natural. See String and Vibration.

Sound is the object of muſic; which is nothing but the art of applying ſounds, under ſuch circumſtances of tone and time, as to raiſe agreeable ſenſations.

The principal affection of ſound, by which it becomes fitted to have this end, is that by which it is diſtinguiſhed into *acute* and *grave*.

This difference depends on the nature of the ſonorous body; the particular figure and quantity of it; and even, in ſome caſes, on the part of the body where it is ſtruck; and this is that which conſtitutes what we call *different tones*.

The cauſe of this difference appears to be no other than the different velocities of the vibrations of the ſounding body. In effect, the tone of a ſound is found, by abundance of experiments, to depend on the nature of thoſe vibrations, whoſe difference we can conceive no otherwiſe than as having different velocities: and ſince it is proved, that the ſmall vibrations of the ſame chord or ſtring are all performed in equal time, and that the tone of a ſound, which continues for ſome time after the ſtroke, is the ſame from firſt to laſt, it follows, that the tone is neceſſarily connected with a certain quantity of time in making each vibration or each wave; or that a certain number of vibrations or waves, accompliſhed in a given time, conſtitute a certain and determinate tone. From this principle are all the phenomena of tune deduced.

If the vibrations be iſochronous, the ſound is called muſical, and is ſaid to continue at the ſame pitch; and is ſaid to be acuter, ſharper, or higher, than any other ſound, whoſe vibrations are ſlower and graver, and flatter or lower, than any other whoſe vibrations are quicker. See Unison.

From the ſame principle ariſe what we call *concords*, &c. which are nothing but the reſults of frequent unions and coincidences of the vibrations of two ſonorous bodies, and conſequently of the waves and undulating motions of the air occaſioned by them.

On the contrary, the reſult of leſs frequent coincidences of thoſe vibrations is what we call a *diſcord*.

Another conſiderable diſtinction of ſound, with regard to muſic, is that by which they are denominated *long* and *ſhort*; not with regard to the ſonorous body's retaining a motion, once received, a longer or a leſs time, though gradually growing weaker, but to the continuation of the impulſe of the efficient cauſe on the ſonorous body, for a longer or ſhorter time, as in the notes of a violin, &c. which are made longer or ſhorter by ſtrokes of different length or quickneſs.

This continuity is properly a ſucceſſion of ſeveral ſounds, or the effect of ſeveral diſtinct ſtrokes, or repeated impulſes, on the ſonorous body, ſo quick that we judge it one continued ſound, eſpecially if it be continued in the ſame degree of ſtrength; and hence ariſes the doctrine of *meaſure* and *time*.

Sounds, again, are diſtinguiſhed, with regard to muſic, into *ſimple* and *compound*, and that two ways. In the firſt, a ſound is ſaid to be compound, when a number of ſucceſſive vibrations of the ſonorous body, and the air, come ſo faſt upon the ear, that we judge them the ſame continued ſound; as in the phenomenon of the circle of fire, cauſed by putting the fire-end of a ſtick in a quick circular motion; where, ſuppoſing the end of the ſtick in any point of the circle, the idea we receive of it there continues till the impreſſion is renewed by a ſudden return.

A ſimple ſound then, with regard to this compoſition, ſhould be the effect of a ſingle vibration, or of ſo many vibrations as are neceſſary to raiſe in us the idea of ſound. In the ſecond ſenſe of compoſition, a ſimple ſound is the product of one voice, or one inſtrument, &c.

A compound ſound conſiſts of the ſounds of ſeveral diſtinct voices or inſtruments, all united in the ſame individual time and meaſure of duration, that is, all ſtriking the ear together, whatever their other differences may be. But in this ſenſe, again, there is a two-fold compoſition; a natural and an artificial one.

The natural compoſition is that proceeding from the manifold reflections of the firſt ſound from adjacent bodies, where the reflections are not ſo ſudden as to occaſion echoes, but are all in the ſame tune with the firſt note.

The artificial compoſition, which alone comes under the muſician's province, is that mixture of ſeveral ſounds, which being made by art, the ingredient ſounds are ſeparable and diſtinguiſhable from one another. In this ſenſe the diſtinct ſounds of ſeveral voices or inſtruments, or ſeveral notes of the ſame inſtrument, are called ſimple ſounds, in contradiſtinction to the compound ones, in which, to anſwer the end of muſic, the ſimples muſt have ſuch an agreement in all relations, chiefly as to acuteneſs and gravity, as that the ear may receive the mixture with pleaſure.

Another diſtinction of ſounds with regard to muſic is that, by which they are ſaid to be *ſmooth* and *even*, or *rough* and *harſh*, alſo *clear* and *hoarſe*: the cauſe of which differences depends on the diſpoſition and ſtate of the ſonorous body, or the circumſtances of the place; but the ideas of the differences muſt be ſought from obſervation.

Smooth and rough ſounds depend principally on the ſounding body; of theſe we have a notable inſtance in ſtrings that are uneven, and not of the ſame dimenſion or conſtitution throughout.

M. Perrault, to account for roughneſs and ſmoothneſs, maintains, there is no ſuch thing as a ſimple ſound; but that the ſound of the ſame chord or bell is a compound of the ſounds of the ſeveral parts of it; ſo that where the parts are homogeneous, and the dimenſions or figure uniform, there is always ſuch a perfect mixture and union of all the ſounds, as makes one uniform and ſmooth ſound: contrary conditions produce harſhneſs. In effect, a likeneſs of parts and figure make an uniformity of vibrations, by which a great number of ſimilar and coincident motions conſpire to fortify and improve each other, and unite, for the more effectual producing of the ſame effect.

This account he confirms from the phenomenon of a bell, which differs in tone according to the part it is ſtruck in; and yet ſtrike it any where, there is a motion over all the parts. Hence he conſiders the bells as compoſed of an infinite number of rings, which, according to their different dimenſions, have different tones, as chords or ſtrings of different lengths have; and when ſtruck, the vibrations of the parts immediately ſtruck ſpecify the tone, being ſupported by a ſufficient number of conſonant tones in other parts. This muſt be allowed, that every note of a ſtringed inſtrument is the effect of ſeveral ſimple ſounds; for there is not only the ſound reſulting from the motion of the ſtring, but that from the motion of the parts of the inſtrument, which has a conſiderable effect in the total ſound, as is evident from hence, that the ſame ſtring on different violins ſounds very differently.

But Perrault affirms the ſame of every ſtring itſelf, and without conſidering the inſtrument. Every part of the ſtring, he ſays, has its particular vibrations, different from the groſs and ſenſible vibrations of the whole; and theſe are the cauſes of different motions and ſounds in the particles, which uniting compoſe the whole ſound of the ſtring, and make an uniform compoſition, in which the tone of the particular part ſtruck prevails, and all the others mix under a due ſubordination with it, ſo as to make the compoſition ſmooth and agreeable. If the parts be unevenly or irregularly conſtituted, the ſound is harſh; which is the caſe in what we call *falſe* ſtrings, and various other bodies, which, for this reaſon, have no certain and diſtinct tone, but a compoſition of ſeveral tones, which do not unite and mix, ſo as to have one predominant to ſpecify the total tone.

As to clear and hoarſe ſounds, they depend on circumſtances that are accidental to the ſonorous body; thus, a voice and inſtrument will be hollow and hoarſe, if raiſed within an empty hogſhead, that yet is clear and bright out of it: the effect is owing to the mixture of other and different ſounds, raiſed by reflections, which corrupt and change the ſpecies of the primitive ſounds.

For ſounds to be fit to obtain the end of muſic, they ought to be ſmooth and clear, poſſeſſing eſpecially the firſt quality: ſince, without this, they cannot have one certain and diſcernible tone, capable of being compared to others, in a certain relation of acuteneſs, of which the ear may judge, and of conſequence they can be no part of the object of muſic.

Upon the whole then, with Mr. Malcolm, we call that an *harmonic* or *muſical* ſound, which, being clear and even, is agreeable to the ear, and gives a certain and diſcernible tune (hence called *tunable* ſound), which is the ſubject of the whole theory of harmony.

Dr. Burney, in the diſcuſſion of the ſubject of this article, obſerves, that enquiries concerning the abſolute production and modification of ſound belong to phyſics; whereas a muſician only examines ſounds comparatively one with the other, and conſiders their proportions and relation as divided into concords and diſcords. (See CONCORD, DISCORD, and RELATION.) And it is only in this light, he ſays, that we ſhall conſider ſound in the reſidue of this article. We ſhall examine ſound under three different heads; the tone, the force, and the quality of tone. Under theſe heads, ſound admits of modification: firſt, from grave to acute; ſecondly, loud and ſoft; thirdly, harſh and ſweet, or dull and brilliant.

We ſhall firſt eſtabliſh it as a principle, that whatever is the cauſe of ſound, its vehicle is the circumambient air;

becauſe the air is the only medium of which we are certain, between the ſounding body and the organ of hearing: that we muſt not multiply bodies unneceſſarily, as the air is ſufficient to explain the formation of ſound; and it is found by an exhauſted receiver, that ſound cannot be produced without air.

The continuance or permanence of ſound can only be occaſioned by the agitation of the air. As long as this agitation continues, the tremulous motion of the air is communicated to the ear, and likewiſe prolongs the ſenſation of ſound. And there is no way more ſimple of accounting for the duration of ſound, than in ſuppoſing that the ſucceſſion of vibrations continues to renew the impreſſion. Further, this agitation of the air, of whatever kind it may be, can only be produced by a ſimilar agitation in the ſeveral parts of the ſounding body; and it is a certain fact, that theſe ſeveral parts of a ſounding body are in conſtant vibration as long as it continues to ſound. If we touch the body of a violoncello, or any inſtrument, while it is ſounding, we feel it tremble under the hand, and we may even *ſee* the ſtring tremble as long as it ſounds. It is the ſame with a bell cauſed to ſound by a blow of the clapper, we may feel and ſee it tremble; and grains of ſand, if ſprinkled on its ſurface, will be ſeen to jump and ſkip. If a ſtring is relaxed, or a bell cracked, there is no longer either ſound or vibration. If, therefore, neither the bell nor the ſtring can communicate to the air no motion but ſuch as they have themſelves, there can be no doubt but that ſound is produced by the vibrations of the ſounding body, and is propagated by ſimilar vibrations, which this tremulous body communicates to the air.

This being ſuppoſed, let us firſt examine what conſtitutes the ratio of ſound, with reſpect to grave and acute.

Rouſſeau, in his article *Son*, ſound, repeats all the experiments for meaſuring and comparing ſound with ſound, which we have given, and ſhall give, under the different heads of tuning glaſſes by water, ſee ARMONICA; ſtrings by weight; by moveable bridges, ſee MONOCHORD; by the number of vibrations, ſee RATIO; by the relative length, thickneſs, and tenſion of a *ſtring*, which ſee; by the beats of organ-pipes, ſee BEAT; by the holes in flutes and hautbois, which ſerve to ſhorten the tube; by the different columns of air, which form the different tones of horns and trumpets: theſe are all upon the ſame principle as the ſons harmoniques of the violin and violoncello. See HARMONICS.

The ſecond point to be conſidered in analyſing ſound, is its *force*, which depends on the vibrations of the ſounding body: the more powerful and ſtrong theſe vibrations are made, the more vigorous and audible is the ſound. A certain limited degree of force can only be given to a pipe or ſtring, beyond which all its proportions are broken, and its tone rendered falſe and diſagreeable to the ear. The velocity of ſound has been conſidered by the moſt eminent philoſophers and mathematicians; but the reſult of their enquiries and experiments have materially varied. Halley and Flamſteed make ſound move, in England, 1070 Fr. feet in a ſecond; and La Condamine 174 toiſes in Peru; while Merſennus and Gaſſendi aſſure us that the wind being favourable or contrary, neither accelerates nor retards the motion of ſound. But ſince the experiments of Derham (Phil. Tranſ.), and the Academy of Sciences at Paris, former calculations are regarded as erroneous.

Without ſlackening its pace, ſound becomes weaker by extent from the place of its production; but if not checked by any obſtacle, nor repreſſed by the wind, it generally moves in the ratio of the ſquares of the diſtance.

Thirdly, as to the difference of ſound in the *quality* of tone, it certainly does not ariſe from its elevation in the ſcale, nor from its force. The tone of a flute and a hautbois, though perfectly in tune together, can never reſemble each other. There will always be a ſoftneſs and ſmoothneſs in the flute, and a ſpirit and agreeable vibration of the reed in the hautbois, which muſt ever prevent ſimilarity; without mentioning the different tones of voices, by which individuals are as well recognized as by their features. See VOICE.

Rouſſeau ſays, a compoſer does not conſider merely whether the ſounds he uſes are high or low, but whether they ſhould be loud or ſoft, rough or ſmooth, dull or brilliant; and he diſtributes them to different inſtruments and voices accordingly; ſometimes in ſolo parts, and ſometimes in *tutti*, or full chorus; at the extremities or medium of inſtruments or voices in piano or forte, as the compoſition ſhall require.

For the appreciable extent of the muſical ſcale or compaſs, it depends on our power of perception, though in nature it is infinite. Lengthen or ſhorten a muſical ſtring to a certain degree, and it produces no ſound. We can neither augment nor diminiſh the compaſs of the flute at our pleaſure, or the length or ſhortneſs of an organ-pipe; both have their limits. All appreciable ſounds are compriſed, according to Euler, within the numbers 30 and 7552. So that by the experiments of this great geometrician, the loweſt ſound of which we can aſcertain the tone, makes 30 vibrations in a ſecond, and the higheſt 7552 vibrations in the ſame time; an interval of nearly eight octaves. See EULER, and COMPASS.

In our preſent ſyſtem of muſic, we have but one octave of twelve ſounds, the reſt are all replicates, recurrencies, or repetitions of theſe twelve ſemitones in the octaves above and below; and if we could uſe all theſe octaves or recurrencies of ſound in the firſt octave, they amount in all to 96, which is the greateſt number of practicable ſounds in muſic, generated by one fundamental.

It is impoſſible to calculate, with ſimilar preciſion, the number of practicable ſounds in the muſic of the ancients. For the Greeks may be ſaid to have formed as many ſyſtems of muſic, as they had different ways of tuning their tetrachords. It appears, in reading their treatiſes of muſic, that theſe different tunings amounted to an indefinite number, including all the changes of genus and mode which a new ſound or key would introduce. See TETRACHORD, and SYSTEM *of the ancient Greeks*.

With regard to the twelve ſounds of the modern ſyſtem, the tuning never changes, and they are always immoveable. Broſſard pretends that they are moveable, founding his opinion of their being often altered by flats and ſharps; but the changing the chord or ſtring, or its ſound, are different things.

SOUNDS, *Harmonical.* See HARMONICS.

The harmonical ſounds, *viz.* the twelfth and ſeventeenth above the principal (as well as ſome others), have been long known to accompany every fundamental ſound; and may naturally, and in general, be ſuppoſed to be produced by the partial or ſeparate vibrations of the ſtring or ſonorous body, ſpontaneouſly dividing itſelf, according to a determinate law, into three, five, or other aliquot parts of the whole, conſidered as unity. The theory of M. Rameau, which has been ſo excellently illuſtrated by M. d'Alembert, in his Elémens de Muſique, is founded on theſe harmonical ſounds. See FUNDAMENTAL *Baſe*, HARMONY, and SYSTEM.

SOUNDS, *Harmonic*, denote alſo a ſingular kind of ſounds, which are produced in certain inſtruments, ſuch as the violin and violoncello, by a particular motion of the bow, and by placing

placing the finger lightly in certain diviſions of the chord or ſtring. On account of their ſweetneſs, they are called *fluted* ſounds. By ſliding the finger lightly from ſharp to flat, from the middle of a chord which is touched at the ſame time with the bow, we hear diſtinctly a ſucceſſion of harmonic ſounds from flat to ſharp, which are very aſtoniſhing to thoſe who are not acquainted with the theory. See Sons *Harmoniques*.

The principle on which this theory is founded is, that if a chord be divided into two parts which are commenſurable with each other, and conſequently with the whole chord, and the obſtacle placed at the point of diviſion obſtructs, in an imperfect manner, the communication of the vibrations from one part to another; when it is ſounded, it will not yield the ſound of the entire chord, nor that of its greater part, but that of the ſmaller part, if it exactly meaſures the other; or if it does not meaſure it, the ſound of the greateſt aliquot common to theſe two parts. Let a chord, as 6, be divided into two parts, as 4 and 2, the harmonic ſound will be produced by the ſmall part, 2, which is the aliquot of the other, 4; but if a chord, as 5, be divided into two parts, as 2 and 3, then, as the ſmall part does not meaſure the greater, the harmonic ſound will proceed from the half, 1, of the ſmall part; unit being the greateſt common meaſure of the two parts 3 and 2, and of the whole chord 5. By means of this law, which is conformable to the experiments of M. Sauveur and of Dr. Wallis, it is eaſy, by a very ſimple calculation, to aſſign to each tone the harmonic ſound which anſwers to it. Whilſt the finger ſlides the length of the chord, we obtain a ſeries of harmonic ſounds, which ſucceed each other rapidly according to the order of the diviſions of the chord, to which the finger is ſucceſſively applied.

The firſt column of the following table exhibits the ſounds which the diviſions of the inſtrument would yield when touched full, and the ſecond column ſhews the *fluted* ſounds correſponding to them when the chord is touched harmonically.

Table of Harmonic Sounds.

The whole chord	gives	the uniſon.
The minor third		the 19th, or double octave of the 5th.
The major third		the 17th, or double octave of the major third.
The fourth		the double octave.
The fifth		the 12th, or octave of the ſame 5th.
The minor ſixth		the triple octave.
The major ſixth		the 17th major, or double octave of the 3d.
The octave		the octave.

After the firſt octave, *i. e.* advancing from the middle of the chord towards the bridge, we ſhall have again the ſame harmonic ſounds in the ſame order on the ſame diviſions, *i. e.* the 19th on the minor 10th, the 17th on the major 10th, &c. Encyclopédie, art. *Harmoniques* Sons. See Harmonics, and Harmony.

Sounds, *Third*, denote thoſe which are produced by ſounding two notes at the ſame time, either on the ſame or on two different inſtruments; and which are almoſt always graver than the loweſt of the two tones that generated them, and are their proper fundamental baſe.

The diſcovery of theſe ſounds has been generally aſcribed to Tartini, who publiſhed an account of them in his "Tratto di Muſica, ſecundo la vera Scienza dell'Armonia," printed at Padua, 1754; but the Encyclopédie, art. *Harmonie*, attributes the firſt diſcovery, though probably unknown to Tartini, to M. Romieu, of the Royal Society of Sciences of Montpellier, who publiſhed an account of it in a memoir in 1752.

The experiment may be made by ſounding the perfect interval of a 3d, 4th, or 5th, &c. either on two ſtrings of the ſame violin, or on two violins played upon at the diſtance of about thirty feet, with a ſtrong bow, and holding out the notes; or with two trumpets, hautbois, or German flutes; the hearer, in the laſt mentioned caſes, playing himſelf in the middle of the interval between the two inſtruments. Thus, *e. gr.* the interval C *e*, or a major 3d, produces C, the octave below the lower note; C ſharp *e*, a minor 3d, produces A, a tenth below the graver tone; B *e*, a 4th, gives E, the octave of the upper note; B *f* ſharp, a 5th, produces an uniſon to B; B *g*, a 6th, generates the double octave below the upper note; and B flat *g*, or the major 6th, produces E flat, the 5th of the lower note, &c.

M. Tartini obſerves, that the third ſound reſulting from the 4th, from two 3ds, from two 6ths, whether major or minor, is the moſt eaſily diſtinguiſhed, becauſe this ſound is always more grave than either of the two which produce it; that the third ſound produced by the 5th is diſtinguiſhed with greater difficulty, becauſe it is an uniſon of a graver ſound; and that it is more difficult to diſtinguiſh it in the tones major and minor, becauſe theſe tones, differing little from one another, are eaſily confounded in the intonation; and for the ſame reaſon, with greater difficulty, in the ſemitones major and minor.

The author, in a ſong compoſed of two parts, diſcovers, by means of two correſponding ſounds, the third ſound reſulting from them; and this, he ſays, is the true baſe of the ſong; and every other baſe will be a paralogyſm. From his experiments and reaſoning he concludes, that if any adjoining two ſimple intervals in the harmonic ſeries 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. be ſounded, the third ſound will always be that of half the ſtring; that the ſmaller the interval is, the farther diſtant is the third ſound: ſo that, *e.g.* the third ſound to the interval of the ſemitone minor G G ſharp, is the 26th below G natural.

M. Serre, of Geneva, in his "Eſſai ſur les Principes de l'Harmonie," printed at Paris in 1753, mentions this diſcovery of Tartini as a fact ſufficiently aſcertained; and adds, that he has produced the ſame effect by means of two fine female voices, as Tartini had done by inſtruments; but he mentions only the third ſound produced by the third major, and that produced by the third minor: and there is this difference between the reſults of theſe two gentlemen. According to M. Tartini, the two ſounds of a third major, as *ut mi*, produced the octave *ut* below *ut*; and according to M. Serre, a double octave: according to the former, the two ſounds of a third minor, *la ut*, produced the tenth major, *fa* below *la*; but according to the latter, the ſeventeenth major below *la*, or the octave under the tenth *fa*. M. Serre takes no notice of a third ſound produced by any other two ſounds, and it does not appear that he made any trials of this kind.

As to the phyſical cauſe of theſe third ſounds, it is much more difficult to offer any plauſible conjectures concerning it, than concerning the harmonical notes mentioned in the preceding article; becauſe all thoſe of the latter kind being more acute than the principal, or generating tone, are, for that reaſon, capable of being actually and immediately produced by the vibrations of certain portions of the ſtring or other ſounding body; whereas, in the third ſounds, a tone is heard always (except in the caſe of the fifth), and often conſiderably below the pitch of either of the bodies whoſe vibrations it accompanies, and which conſequently cannot immediately proceed from either of theſe bodies. To take the firſt of the above-mentioned intervals, that of the greater third, for an example: a third ſound is here heard, ſuch as would be produced by the actual vibration of a ſtring of the ſame diameter and tenſion with, but of double the length of, that which produced the loweſt note of the interval. As no ſuch ſtring, however, is employed in the experiment, we are obliged to ſeek for the cauſe of this new ſound in the air, or other medium of ſound, or in the organ of hearing, or in ſome internal modification of the ſenſitive faculty.

As the immenſe variety of our ſenſations of colour is juſtly ſuppoſed to be produced by an equal diverſity of coloured particles of light, each highly qualified to excite one particular ſenſation and no other, ſo ſome, with M. Mairan, have ſuppoſed, that our numerous and diverſified ſenſations of muſical tones are not produced by the undulations of the air, conſidered in its whole maſs, but by aerial particles, ſpecifically different in elaſticity, magnitude, figure, &c. each capable of exciting, by its motions or other modifications, the idea of only one determinate tone. Therefore we might ſay, that the two orders of particles which give the tones C and *e*, either by an harmonical congruity in their ſpring with that ſet of particles which give the third ſound C below, or by ſome other peculiar affinity to them, are qualified, by their joint action on theſe laſt-mentioned particles, to give them that particular modification, by which they excite in us the ſenſation of that ſpecific tone to which they are adapted. Or, may we not conceive in general, that a mixture of two given tones may excite the idea of a third and different ſound, in ſome ſuch manner as two given colours, *e. g.* blue and yellow; nay, the paſt impreſſions of theſe colours excite the idea of green, different from both of them.

But if the effect is produced merely by the organ of hearing, we may obſerve, that, from a conſideration of the ſpiral and conical ſtructure of the cochlea, ſome phyſiologiſts have been tempted to imagine, that the branches or filaments of the auditory nerve, after paſſing out from the nucleus or axis of the cochlea, are ſtrained upon the ſpiral plates, like the radii of a circle, and become gradually ſhorter and ſhorter toward its apex. It may be ſuppoſed likewiſe, that of theſe nervous ſtrings, the longeſt, which are in the baſis of the cochlea, are adapted to receive the tremors or other impreſſions, and convey to the mind the ideas, of grave tones; and the ſhorter nervous chords, fixed more towards the apex of the cone, thoſe of acute ſounds. This being allowed, and taking the former interval C *e* for an example, it may be ſaid that the tone C, beſides acting on the nervous chord appropriated to excite the idea of that tone, muſt act likewiſe on another nervous chord of double its length, ſituated towards the baſis of the cochlea, &c. and which is naturally adapted to receive and tranſmit to the mind C, the octave below; but which the upper tone C now divides into two equal parts, each giving tones uniſon to the ſaid note C. The tone *e*, in like manner, will excite five equal vibrations in each of the halves of this nervous chord; all which, likewiſe, produce ſenſations uniſon with itſelf. Theſe phenomena at leaſt are invariably obſerved to be produced in muſical ſtrings. Thus we obtain the uniſons to C and *e*: and farther, the laſt-mentioned chord thus vibrating in two and in ten parts, and from one extremity of it to the other, may fairly be ſuppoſed to vibrate in its whole length; in which caſe it muſt excite in the mind the idea of its own fundamental tone, the third ſound C, an octave below the firſt of theſe notes, and a tenth below the latter. See, on the ſubject of this article, Encyclopédie, art. *Baſſe* FONDAMENTALE. Principles and Power of Harmony, 4to. 1771, and Monthly Rev. vol. xlv. p. 371, &c.

SOUND, in *Geography*, denotes a ſtrait or inlet of the ſea, between two capes or head-lands.

The Sound is uſed, by way of eminence, for that famous ſtrait which joins the German ſea to the Baltic.

It is ſituate between the iſland of Zealand and the coaſt of Schonen. It is about ſixteen leagues long, and in general five broad, excepting againſt the caſtle of *Cronenburg*, (which ſee,) where it is but one; ſo that there is there no paſſage for veſſels but under the cannon of the fortreſs.

This was firſt erected for the better commanding of the Sound, as was alſo Helſinburgh, on the oppoſite ſhore in Schonen, for the protection of ſhips from pirates, then numerous in that ſea.

This has given occaſion to the Danes to ſettle a toll on all veſſels, which is ſaid to be one of the beſt revenues of the crown of Denmark; and to forbid all pilots from paſſing through the Great and Little Belt, which are two other inlets into the Baltic, though ſomewhat leſs commodious than the former.

All nations who traffic into this part of the North are ſubject to this toll: the Swedes, indeed, were exempted from it by the treaty of 1644, but by the treaty of 1720, they are excluded the privilege, and put on the ſame footing with their neighbours.

By the treaty of Spire, made between the Danes and Charles V. in behalf of his Netherland ſubjects, the toll for this paſſage was fixed at two roſe nobles for a ſhip of two hundred tons; yet, in the year 1640, the ſame was raiſed to upwards of five hundred rix-dollars.

The connivance of our king James I. who had married a daughter of Denmark, and the wars which the Hollanders had been long engaged in for their liberty, furniſhed the occaſion for ſo grievous an exaction. Of late years, the toll has been again reduced to an eaſier footing.

Cromwell was bent on extorting this paſſage from the Danes, and had probably effected it, but that, before the fleet for that purpoſe arrived there, he died.

However, in 1659, England, Holland, and France, by treaty, obliged Denmark to ſtipulate, that it ſhall never be increaſed upon the ſaid three nations, who are mutual guarantees to this treaty.

The origin and progreſs of this impoſition (which, from an eaſy contribution, of which we have an account ſo early as 1348, voluntarily paid by merchants for maintaining lights on certain places of the coaſt, and for protection of ſhips from pirates, and of which the king of Denmark was only treaſurer or truſtee, grew at length to be a heavy burden on trade, as well as a kind of ſervile acknowledgment of his ſovereignty of theſe ſeas) is given in lord Moleſworth's Account of Denmark, chap. iii. p. 11. ſeq.

As to the preſent ſtate of this toll, Dr. Buſching, in his New Geography, obſerves, that it is on an equal footing with all nations, excepting the Hamburghers, who pay more than others: the Engliſh, Dutch, Swediſh, and French ſhips, are not ſearched when provided with proper paſſes, according to treaties; and pay down only 1 *per cent.* for ſuch goods as are not ſpecified in the tarif. But all other nations pay 1½ *per cent.* and muſt ſubmit to be ſearched. With regard to the Hanſe Towns, on the Baltic, there is a great variety in the toll they pay, for almoſt every one of thoſe towns is treated with in particular. See DENMARK and ELSINEUR.

On the Sound, accounts are kept in rix-dollars, of 4 orts, which contain 96 ſkillings Daniſh, or 48 ſhillings Hamburgh

burgh money. The tolls paid at the paſſage of the Sound are reckoned in rix-dollars, Swediſh ſpecie, which are $12\frac{1}{2}$ *per cent.* better than crown money, and therefore $19\frac{17}{37}$ *per cent.* better than Daniſh currency; but this rix-dollar is $2\frac{5}{8}$ *per cent.* worſe than the effective rix-dollar ſpecie of 7 marks 6 ſkillings Daniſh currency. The tolls are alſo ſometimes ſettled in crown money. In paying duties at the Sound, the ſhippond is reckoned for 300 lbs.; the ſtein or ſtone for 30 lbs.; the Ruſſian berkovitz for 300 lbs.; and the pood for 30 lbs. Here are alſo certain regulations for foreign meaſures, an abſtract of which is given in Kelly's Cambiſt.

Sound, in the *Manege.* A horſe is ſaid to be ſound that does not halt. When a jockey ſells a horſe he warrants him ſound hot and cold; that is, that he does not halt either when you mount him or when he is heated, nor yet after alighting, when he ſtands and cools.

Sound, an inſtrument which ſurgeons introduce through the urethra into the bladder, in order to diſcover whether there is a ſtone in this viſcus or not. The ſound is uſually made of very highly poliſhed ſteel, that it may be well calculated for conveying to the ſurgeon's fingers, a ſenſation of any thing againſt which its end may ſtrike. It is alſo generally leſs curved than a catheter, ſo that its end may be more eaſily inclined to the lower part of the bladder, where the ſtone is moſt frequently ſituated.

SOUND-BOARD, or *Wind-cheſt*, of an organ, is the principal part of that moſt noble and comprehenſive inſtrument, and that which feeds all the pipes with wind. See Organ.

The ſound-board, or ſommier, as it is called in France, is a reſervoir, into which the wind drawn in by the bellows is conducted by a port-vent, and thence diſtributed into pipes placed over the holes of its upper part. The wind enters the pipes by valves, which are opened by preſſing the keys, after drawing the regiſters by the ſtops, which prevent the air from going into any of the pipes, except thoſe required. Organs, whoſe longeſt pipe in the diapaſon is four feet, have their ſound-board from five to ſix feet. Organs of ſixteen feet have two ſound-boards, which communicate the wind from one to the other, by means of a pewter port-vent.

SOUND-HOLM, in *Geography*, one of the ſmaller Shetland iſlands, near the S.W. coaſt of Yell.

SOUNDING, in *Navigation*, the act of trying the depth of the water, and the quality of the bottom, by a line and plummet, or other artifice.

There are two plummets uſed for this purpoſe; one of which is called the hand-lead, weighing about 8 or 9 lbs. and the other the deep-ſea lead, which weighs from 25 to 30 lbs. and both are ſhaped like the fruſtum of a cone or pyramid. The former is uſed in ſhallow waters, and the latter at a great diſtance from the ſhore, particularly on approaching the land after a ſea voyage. Accordingly, the lines employed for this purpoſe are called the deep-ſea lead-line and the hand-lead line. The hand-lead line, which is uſually 20 fathoms in length, is marked at every 2 or 3 fathoms; ſo that the depth of the water may be aſcertained either in the day or night: at the depth of 2 and 3 fathoms, there are marks of black leather; at 5 fathoms, there is a white rag; at 7, a red rag; at 10, and at 13, black leather; at 15, a white rag; and at 17, a red one.

Sounding with the hand-lead, which the ſeamen call heaving the lead, is generally performed by a man who ſtands in the main-chains to windward. Having the line all ready to run out, without interruption, he holds it nearly at the diſtance of a fathom from the plummet, and having ſwung the latter backwards and forwards three or four times, in order to acquire the greater velocity, he ſwings it round his head, and thence as far forwards as is neceſſary; ſo that, by the lead's ſinking whilſt the ſhip advances, the line may be almoſt perpendicular when it reaches the bottom. The perſon ſounding then proclaims the depth of the water in a kind of ſong, reſembling the cries of hawkers in a city; thus, if the mark of 5 is cloſe to the ſurface of the water, he calls, 'by the mark 5,' and as there is no mark at 4, 6, 8, &c. he eſtimates thoſe numbers, and calls, 'by the dip 4, &c.' If he judges it to be a quarter or a half more than any particular number, he calls, 'and a quarter 5,' and 'a half 4,' &c. If he conceives the depth to be three-quarters more than a particular number, he calls it a quarter leſs than the next: thus, at 4 fathoms $\frac{3}{4}$, he calls, 'a quarter leſs 5,' and ſo on.

The deep-ſea lead-line is marked with two knots at 20 fathoms, 3 at 30, 4 at 40, &c. to the end. It is alſo marked with a ſingle knot at the middle of each interval, as at 25, 35, 45 fathoms, &c. To uſe this lead more effectually at ſea, or in deep water on the ſea-coaſt, it is uſual previouſly to bring-to the ſhip, in order to retard her courſe: the lead is then thrown as far as poſſible from the ſhip on the line of her drift, ſo that as it ſinks, the ſhip drives more perpendicularly over it. The pilot feeling the lead ſtrike the bottom, readily diſcovers the depth of the water by the mark on the line neareſt its ſurface. The bottom of the lead being alſo well rubbed over with tallow, retains the diſtinguiſhing marks of the bottom, as ſhells, ooze, gravel, &c. which naturally adhere to it.

The depth of the water, and the nature of the ground, which are called the ſoundings, are carefully marked in the log-book, as well to determine the diſtance of the place from the ſhore, as to correct the obſervations of former pilots. Falconer.

For a machine to meaſure unfathomable depths of the ſea, ſee Altitude.

Sounding *the Pump*, at *Sea*, is done by letting fall a ſmall line, with ſome weight at the end, down into the pump, to know what depth of water there is in it.

Sounding, in *Surgery*, the operation of introducing the ſound. See Searching *for the Stone.*

SOUNDIPOUR, in *Geography*, a town of Hindooſtan, in Bahar, 8 miles S. of Rotaſgur.

SOUNE, a ſmall iſland in the Indian ſea, near the coaſt of Africa. S. lat. 10° 57′.

SOUNISA, a town of Aſiatic Turkey, in the government of Sivas; 27 miles N. of Tocat.

SOUNMEN Harho Hotun, or Soumen *Char*, a town of Chineſe Tartary, in the province of Hami; 15 miles N.W. of Hami-Hotun.

SOUP, or Soop, a kind of pottage made of bread, and broth, or of the juice of fleſh, or other matters, uſually ſerved at the beginning of a meal.

The word is French, formed from the Italian, *zuppa*, or *ſuppa*, of the Latin, *ſapa*, wine boiled away to a third part. Others derive it from the Celtic, *ſouben*, which ſignifies the ſame.

Soup is eſteemed eſſential to a French dinner. Sometimes they heighten the reliſh by the addition of onions, or leeks, or cabbage, or turnips, &c.

Soup, *Portable*, is a kind of cake, formed of concentrated broth, which, being freed from all fat, and having by long boiling evaporated the moſt putreſcent parts of the meat, is reduced to the conſiſtence of a glue, as in reality it is, and will, like other glues, in a dry place, keep ſound for years together. Sir John Pringle inclines to believe, that the gelatinous parts of animal ſubſtances, ſuch as compoſe theſe cakes, are not of a nature much diſpoſed to putrefy. But, however that be, captain Cook obſerves, that, in his voyage (ſee Scurvy), this ſoup was the means of making his people eat a greater quantity of greens than they would have done otherwiſe, and ſo far we muſt allow it to have been virtually antiſeptic. For the method of preparing cakes for portable ſoup, by Chaptal, &c. ſee Jelly.

Soup, in *Agriculture*, a term applied to ſuch liquid animal food or proviſions, as are formed by cutting various dry materials, ſuch as hay, ſtraw, &c. and blending them with liquid matters; and alſo to ſuch as are prepared with meals of different ſorts, ſuch as that of oats, peas, beans, and others of a ſimilar kind. By this practice, the ſubſtances are not only found to go much farther, but to have a much greater effect in promoting the growth or fattening of the animals.

The advantages of preparing the food, and feeding ſome ſorts of animals in this way, are now well known, as ſuch food not only goes much farther, but affords a much greater improvement in the animals. The advantage of feeding young hogs with ſoups of theſe kinds are faſt becoming well underſtood; and the animals are found to go on far better with them than in the old methods of proceeding, but there is ſtill much to be done in regard to the modes of preparing of them, and the conditions in which they ſhould be at the time they are given. See Swine.

SOUPROSSE, in *Geography*, a town of France, in the department of the Landes; 6 miles S.E. of Tartas.

SOUR. See Sur.

Sour, a river of France, which riſes near Baſtogne, in the department of the Foreſts, and runs into the Moſelle, 3 miles above Treves.

Sour *Guſlan*, a town of Algiers, near mount Jurjura.

Sour-*Dock*, in *Botany*. See Sorrel.

Sour-*Food*, in *Agriculture*, ſuch food as has been rendered ſour by the acetous fermentation, and which has lately been ſaid to be of ſuperior utility in the fattening of animals. Oxen as well as ſwine have lately been ſuppoſed by ſome to feed faſter, where their food has been brought into this condition before uſing it, than when uſed in the natural ſtate. See Stall-*feeding*.

Sour-*Gourd*, in *Botany*. See Adansonia.

Sour-*Graſs*, in *Agriculture*, the coarſe tufty herbage uſually met with about the dung-heaps in fields, and where there is much ſtagnant moiſture. It is obſerved by Dr. Darwin, that where a piece of graſs is over-run with tuſſocks of ſour-graſs, which often happens near towns, he has been informed, that lime or coal-aſhes ſpread on them, would render the graſs ſweeter, ſo that horſes or cattle would eat it. But he ſuppoſes the more certain and advantageous management would conſiſt in mowing it frequently, and giving it to horſes or cattle in the ſtable or ſtall; as he believes they will eat it greedily after it has been a few hours withered, and thus the land will not only yield more provender at preſent, but after a few mowings a ſweeter graſs will riſe in the place of that which was of a bad kind, or of too luxuriant growth, for which purpoſe it ſhould be mowed as near the ground as may be; or if it be frequently mowed during the ſummer, and left on the ground, ſome cattle will eat it, when it is withered to a certain degree; by which the diſagreeable flavour of it is probably leſſened or deſtroyed. Proper drainage and cloſe feeding ſuch lands, are likewiſe uſeful methods of bringing them into a ſtate of better and ſweeter graſs.

Sour-*Kroute*. See Croute.

Sour-*Land*, in *Agriculture*, a term applied to cold clayey ſoils, and ſuch as have ſome ſort of impervious ſtrata at no great diſtance from the ſurface, by which they are kept in a wet and ſour ſtate. See Clay, and *Clayey* Soil.

Sour-*Sop*, in *Botany*. See Annona.

SOURA, in *Geography*, a town of the Arabian Irak, on the Euphrates; 153 miles N.W. of Baſſora.

Soura, a town of Portugal, in Eſtremadura, ſituated on the river Soure; 7 miles S.S.E. of Montemor o Velho.

SOURABAYA, a pleaſant town on the N.E. coaſt of the iſland of Java, ſituated on the banks of a river, a mile and a half diſtant from the ſea-ſhore, ſo that only the flag-ſtaff can be ſeen from the road. The river is navigable up to the town for veſſels of 100 tons burthen, and the bank on one ſide is made convenient for tacking. The Chineſe carry on a conſiderable trade here, and have a town on the ſide of the river oppoſite to Sourabaya. The country near the town is flat, and the ſoil light, ſo that they plough with a ſingle bullock, or buffalo. The latitude in Sourabaya road is 7° 11′ S. The Dutch had a reſident in this place, with the rank of ſenior merchant, and the title of the commander of the eaſtern diſtrict. The chief commodity of this government is rice. The interior parts of the country, near the mountains, are infeſted with a breed of fierce tigers, which render travelling dangerous. Here is alſo a breed of horſes, ſmall, but handſome and ſtrong. The Javaneſe in the vicinity are numerous. Stavorinus's Voyage, vol. ii.

SOURAH, a town of Hindooſtan, in the circar of Aurungabad; 20 miles S.S.E. of Jaffierabad.

SOURAN, a town of Perſia, in Khoraſſan; 255 miles N. of Herat.

SOURAPATA, a kingdom on the S. coaſt of the iſland of Java.

SOURATAU HOUTCHIN, a town of Chineſe Tartary, in the country of the Monguls. N. lat. 53° 54′. E. long. 114° 34′.

SOURDEVAL, a town of France, in the department of the Channel, and chief place of a canton, in the diſtrict of Mortain; 4 miles N. of Mortain. The place contains 3896, and the canton 9580 inhabitants, on a territory of 115 kiliometres, in 9 communes.

SOURDON, in *Natural Hiſtory*, the name of a bivalve ſhell-fiſh found on the coaſt of Poitou, and other places. It is a ſmall fiſh, its length being little more than an inch, and its breadth about three quarters of an inch; its ſhells are both conſiderably convex; the outer ſurface is deeply furrowed, but the inſide is perfectly ſmooth: the fiſh buries itſelf lightly in the ſand, and has a pipe of communication, which it raiſes to the ſurface; but as this creature never buries itſelf deep, the pipe is neceſſarily very ſhort; but they are cut into ſeveral ſegments at the extremity, and appear as it were fringed, and have ſeveral hairs growing from theſe ſegments. The ſourdon is capable of a progreſſive motion by means of a limb, ſomewhat reſembling that of the other chamæ, but more than any approaching the nature of a leg, as it in ſome meaſure repreſents, in miniature, a human leg with a clumſy boot upon it: by means of this limb the creature can eaſily bury itſelf in the ſand, or riſe up out of it, or move horizontally on the ſurface, and that as well backwards as forwards, and with more ſwiftneſs than could well be ſuppoſed. Mem. Acad. Par. 1710.

SOURE, in *Geography*, a river of Portugal, which runs into the Mondego; 4 miles S. of Montemor o Velho.

SOURERAH, a town of Hindooſtan, in the circar of Cicacole; 40 miles W.N.W. of Ganjam.

SOURI, a town of Perſia, in the province of Lariſtan, on the Perſian gulf; 38 miles S.W. of Ormus.

SOURING *Lime for Mortar and Plaſter*, in *Rural Economy*, the practice of macerating and rendering it proper

per for theſe uſes. It has been ſtated by the writer of an "Eſſay on Quicklime as a Cement," that when lime is to be employed for making plaſter, it is of great importance that every particle of the limeſtone be ſlaked before it is worked up; for, as the ſmoothneſs of the ſurface is the circumſtance moſt wiſhed for in plaſter, if any particles of lime ſhould be beaten up in it, and employed in work before they have had ſufficient time to fall, the water ſtill continuing to act upon them after the materials have been worked up, will infallibly ſlake ſuch particles, which will then expand themſelves in a forcible manner, and be productive of thoſe excreſcences upon the ſurface of the plaſter, which are commonly known by the name of bliſters. Conſequently, if it be intended to have a perfect kind of plaſter, which is capable of remaining ſmooth on the ſurface and free from bliſters, there is an abſolute neceſſity for allowing the lime of which it is compoſed, to lie for a conſiderable length of time in maceration with water, before it is wrought up into plaſter, which is a proceſs or operation that is here termed ſouring. Where the limeſtone is of a pure quality, and has been very perfectly calcined or burnt, there will ſeldom be any danger of the whole of the lime falling at firſt; but where it has been leſs perfectly burnt, there will be many particles, which will require to lie a long time before they will be completely reduced into powder. This macerating proceſs or operation is conſequently more neceſſary with impure than pure lime; but ſtill it ought on no occaſion to be omitted or neglected, as there is not the ſmalleſt probability, but that ſome bliſters would appear on the ſurface of plaſters made with even the pureſt lime, when worked up and applied immediately after being ſlaked, without undergoing this ſouring proceſs in ſome degree.

The practice is alſo common of ſouring the lime when it is intended for being uſed in mortar; but although it is not ſo indiſpenſably neceſſary in this caſe, as in that where it is deſigned for plaſter, yet, when properly performed, it is evident, it is ſaid, that it muſt even in this inſtance too be of utility; as any dry knots of lime that may fall after the mortar is uſed, muſt have a tendency to diſunite the parts of it, which have already been united, and to render the mortar or cement much leſs perfect than if the whole had been properly mixed up with the materials and allowed to ſour before uſing. More circumſpection is, however, requiſite, it is ſaid, in ſouring lime for mortar than for plaſter; for, as it is not neceſſary that plaſter ſhould be endowed with a ſtony degree of hardneſs, there is no loſs ſuſtained by allowing a great proportion of the lime which is deſigned for that purpoſe to abſorb its air before it be uſed; for a very ſmall quantity of cauſtic or quicklime will be ſufficient to unite the whole into one ſlightly coherent maſs. Conſequently, the only circumſtance which is neceſſary to be attended to in ſouring lime for plaſter is, that it be allowed to macerate long enough, as there is no danger of ever erring on the oppoſite extreme. It is indeed neceſſary, it is ſaid, on ſome occaſions, it ſhould lie a very long time, before any certainty can be had, that all the particles are thoroughly ſlaked, as pieces of lime-ſhells have been known to lie upwards of ſix months expoſed to all the changes of the winter weather, and fall after that period. Such ſlightly burnt ſtones are indeed, it is ſaid, uſually ſeparated in ſifting the lime for plaſter; but as ſome ſmall chips may eſcape, it is always the ſafeſt way to allow lime to lie in the ſour a very conſiderable length of time. Another advantage of ſome conſequence likewiſe, it is ſaid, attends this practice; as, if by ſuch means a large proportion of the lime be allowed to abſorb its air, and become in the mild or effete ſtate, when it is wrought or beaten up for uſe, the water can have no ſenſible effect upon this mild lime; it will only ſeparate the particles of the cauſtic lime more perfectly from each other, ſo as to permit it to dry without cracks of any kind, and render the ſurface of the plaſter a great deal more ſmooth and entire, than could have been the caſe, if the whole had been made uſe of while in the perfectly cauſtic ſtate. By this means too, thoſe cryſtalline exudations, which are ſo common on walls newly plaſtered, will be the beſt and moſt effectually prevented. On all which accounts, the practice of ſuffering lime, which is deſigned for plaſter, to macerate or ſour a long time with water, ſhould never, it is ſaid, except in caſes of neceſſity, be neglected or overlooked.

However, as lime, from the moment of its being fully ſlaked, begins to abſorb air, and continues to take up more and more every minute from that time until it becomes perfectly mild or effete, ſo as to be rendered gradually leſs and leſs proper for forming mortar of any kind, it neceſſarily follows, that where lime deſigned for this purpoſe is permitted to lie long in the ſour, a great part of it will be converted into chalky matter, or uncryſtallized mild or effete lime, in which ſtate it will be capable of having ſo much ſand added to it, or of forming ſo good a mortar as would have been the caſe, if a larger proportion of the ſandy material had been made uſe of in the firſt place, and been wrought up as ſpeedily as poſſible, without ſo much ſouring, into mortar, and immediately made uſe of. The evil will alſo be increaſed where the lime has been but ſlightly burnt, conſequently the beſt burned lime ſhould always be preferred for this uſe, which, when carefully ſifted after ſlaking, will ſoon fall ſufficiently for this purpoſe; as the main point here is to have the mortar firm and binding; and the falling or burſting of very ſmall unſlaked particles of lime in the mortar afterwards, will not be productive of ſuch evident inconvenience as is the caſe in the making and uſing of plaſter. In the making of good mortar, it will conſequently be neceſſary to get the beſt burnt lime, and to only ſuffer it to macerate or ſour with water a very ſhort time before it is wrought and applied. The beſt burnt lime, however, moſtly requires ſome days to macerate and ſour with water, before the whole becomes fully ſlaked and fallen for this uſe.

This doctrine of the nature and utility of the ſouring proceſs in the making of theſe ſubſtances is ſuppoſed to receive additional proof and ſupport from the practice which was followed by the ancients, which is very ſimilar to this, if the accounts given of it by Vitruvius and Pliny can be depended on. The former, it is ſaid, expreſsly recommends that the lime ſhould be macerated or ſoured in water, for exactly the ſame reaſons that have been already ſeen, as it is only by that means, he aſſerts, that the plaſter can be prevented from bliſtering. His words are theſe: "tuuc de albariis operibus eſt explicandum. Id autem erit recte, ſi glebæ calcis optime, ante multo tempore quam opus fuerit, macerabuntur. *Numque cum non penitus macerata, ſed recens ſumitur——habens latentes crudos cuculos, puſtulas omittit.——Qui calculi diſſolvunt et diſſipant tectorii politiones.*" Vit. lib. vii. c. 2.

The latter points out, it is ſaid, in a ſtill more clear manner, the difference between the quality of the lime, which is neceſſary for making mortar and plaſter:—a certain proof, it is conceived, that the ancients had been very accurate in the obſerving of facts, as they could have no idea of the reaſoning by which thoſe facts might have been corroborated or explained.

"Ruinarum urbis," ſays he, "ea maxime cauſa, quod ſurto, calcis *ſine ferrumine ſuo cæmenta* componuntur. *Intrita* quoque *quo vetuſitor, eo melior.* In antiquarum (antiquis) ædumligibus invenitur, ne recentiore trima uteretur redemptor; idio nulla (nullæ) tectoria eorum rimæ fædavere." Plin. Hiſt. lib. xxxvi. c. 23.

In this paſſage, the writer ſtrongly contraſts, it is ſaid, mortar (*cæmenta*) with plaſter (*intrita*). The firſt, he contends, by implication, ought always to be compoſed of lime *cum ferrumine ſuo;* that is, lime which ſtill retains its *gluten*, cementing or adhering principle; lime that ſtill keeps or poſſeſſes that quality, by which it is enabled to unite detached matters into a ſolid body, and *glue* them, as it were, together. In other places of the ſame work, the author, it is ſaid, deſcribes it as *calcis quam vehementiſſimæ;* lime in its moſt acrid ſtate; that is, perfectly *cauſtic* lime. And this quality he plainly hints, it gradually loſes by time, ſo as to come at length to be *ſine ferrumine ſuo:* in which ſtate, as it is impoſſible to become a good firm mortar or cement for building with, thoſe who make uſe of it as ſuch are ſeverely reprehended. But although the practice of uſing old and inert lime for mortar is condemned, it is immediately added, as has been ſeen above, that for plaſter it is better than new, becauſe it is not ſo ſubject to crack in the work.

Thus it would ſeem, that the importance of the ſouring operation or proceſs, for theſe different purpoſes, was well known at an early period, though the principles on which its utility depended, were probably far from being underſtood.

SOURIS, Lake *des*, in *Geography*, a lake of Canada, the direction acroſs which is amongſt iſlands, N.W. by W. ſix miles. In this traverſe is an iſland remarkable for a very large ſtone in the form of a bear, on which the natives have painted the head and ſnout of that animal; and here they were alſo formerly accuſtomed to offer ſacrifices. This lake is ſeparated only by a narrow ſtrait from the lake du Serpent, which runs N.N.W. ſeven miles, to a narrow channel, that connects it with another lake, bearing the ſame name, and running the ſame courſe for 11 miles, when the rapid of the ſame denomination is entered on the W. ſide of the lake. A ſingular circumſtance is obſervable here, that for three or four miles on the N.W. ſide of this lake, there is an high bank of clay and ſand, clothed with cypreſs trees, no ſuch caſe occurring on any other lake deſcribed by Mackenzie; as they are bounded, particularly on the N., by black and grey rocks. Mackenzie's Travels, Introd.

Souris, in the *Manege*, is a cartilage in the noſtrils of a horſe, by means of which he ſnorts. See Snort.

The cutting of this cartilage is called in French *eſſouriſſer*.

SOURMAN, in *Geography*, a town of Thibet; 250 miles N.E. of Laſſa.

SOURNAT, a town of France, in the department of the Correze; 9 miles N.N.W. of Uſſel.

SOURNIA, a town of France, in the department of the Eaſt Pyrenées, and chief place of a canton, in the diſtrict of Prades; 7 miles N. of Prades. The town contains 842, and the canton 3718 inhabitants, on a territory of 160 kiliometres, in 12 communes.

SOUROUBEA, in *Botany*. See Ruyschia.

SOURTOU, in *Geography*, a town of Chineſe Tartary. N. lat. 44° 51′. E. long. 94° 24′.

SOURUNGE, a town of Hindooſtan, in the circar of Cicacole; 35 miles S.W. of Ganjam.

SOUSEL, a town of Portugal, in Alentejo, containing about 1300 inhabitants; 6 miles N.N.W. of Eſtremoz.

SOUSOU, a town of Aſiatic Turkey, in Natolia; 24 miles N. of Satalia.

SOUSOUGHERLIK, a town of Aſiatic Turkey, in Natolia; 20 miles S.E. of Balikeſri.

SOUSSERAC, a town of France, in the department of the Lot; 6 miles E. of St. Ceré.

SOUSTONS, a town of France, in the department of the Landes, and chief place of a canton, in the diſtrict of Dax. The place contains 2578, and the canton 6604 inhabitants, on a territory of 417½ kiliometres, in 11 communes.

SOU-TÇHEOU, Soo-choo, or Soo-choo-foo, a city of China, of the firſt rank, in the province of Kiang-nan, ſituated in the vicinity of Nan-lum, on a river which communicates with the lake Tain-hoo. This is reckoned one of the moſt agreeable cities in China, and compared by Europeans, who have ſeen it, with Venice, with this difference, that the latter is built in the ſea, and Sou-tcheou is interſected by canals of freſh water, branching from the principal canal, over each of which branches is erected an elegant ſtone-bridge. In the walls of the city are turned ſeveral arches, through which the canal paſſes. Under theſe walls are drawn up an immenſe number of veſſels; and one ſhip-building yard contained, when this city was viſited by the embaſſy, ſixteen upon the ſtocks, cloſe to each other, each of the burden of about two hundred tons. The ſuburbs are very extenſive. Sou-tcheou is large and very populous; the houſes are neat and well built, and the inhabitants reſpectably dreſſed, moſtly in ſilk. The women, ſays ſir John Staunton, were fairer than thoſe in the north; many of whom wore a ſmall cap of black ſatin, adorned with ſpangles upon the forehead, brought down to a peak above the eye-brows; and they had ear-pendents of gold or cryſtal.

There is not perhaps in the univerſe, according to Groſier's account, a country more delightful, either for pleaſantneſs of ſituation, or mildneſs of climate. The air is ſo temperate, proviſions ſo plentiful and cheap, the ſoil ſo fruitful, and the manners of the people ſo gentle, that this city is conſidered as the paradiſe of China. "Above (ſay the Chineſe authors) is the celeſtial paradiſe; but the paradiſe of this world is Sou-tcheou." Upon obſerving the continual motion of its immenſe number of inhabitants, and the confuſion occaſioned every where by their commercial intercourſe with ſtrangers, one would be induced to believe that the trade of all the provinces centered in it. The brocades and embroideries manufactured here are in great requeſt through the whole empire. The juriſdiction extends over only eight cities, one of which is of the ſecond claſs, and the reſt of the third; but all theſe cities are beautiful, and about two or three leagues each in circumference. In the vicinity of this city is found that remarkable tree which furniſhes tallow, the "croton ſebiferum" of Linnæus. See Croton. N. lat. 31° 22′. E. long. 120°.

SOUTELLO, a town of Portugal, in the province of Beira; 17 miles W. of St. Joao do Peſqueira.

SOUT-EL-TELL, a mountain of Algiers; 30 miles N.E. of Tremecen.

SOUTERRAINE, La, a town of France, in the department of the Creuſe, and chief place of a canton, in the diſtrict of Gueret; 17 miles W. of Gueret. The place contains 2665, and the canton 10,237 inhabitants, on a territory of 275 kiliometres, in 11 communes. N. lat. 46° 15′. E. long. 1° 34′.

SOUTH, one of the four cardinal points of the compaſs. See Cardinal *Points*.

South, Robert, in *Biography*, a divine of the church of England, eminent for learning, talents, and wit, was the ſon of a London merchant, and was born at Hackney in 1633.

1633. He was educated at Weſtminſter ſchool by the celebrated Buſby, from whence he was elected to Chriſtchurch, Oxford. Here he was ſoon diſtinguiſhed for his claſſical attainments, of which one of his products was an elegant Latin poem addreſſed to Oliver Cromwell, on the concluſion of the Dutch war. Another poem of his, which was much read and applauded, was entitled "Muſica Incantans," which was afterwards printed ſeparately, at Dr. Fell's requeſt. In 1657 he commenced M.A., and in the following year he received holy orders from one of the deprived biſhops, and being ſoon after choſen to preach the aſſize ſermon before the judges, he made a violent attack upon the Independents, which ingratiated him with the Preſbyterians. Soon after the Reſtoration, he was choſen public orator of the univerſity. In this office he acquitted himſelf ſo much to the ſatisfaction of lord Clarendon, when complimenting him at his inveſtiture as chancellor of the univerſity, that he was taken under the protection of that eminent man, and appointed his domeſtic chaplain. He was promoted to a prebend of Weſtminſter in 1663, and was in the ſame year admitted to the degree of D.D. He ſoon ſucceeded to a canonry of Chriſtchurch, and in 1673 he attended as chaplain to the younger ſon of the earl of Clarendon, in an embaſſy to Poland. On his return he was preſented to the rectory of Iſlip, in Oxfordſhire, and became greatly diſtinguiſhed by his turn for humorous ſarcaſm, in which he indulged even in the pulpit. During the reign of Charles II. Dr. South was, from principle, a ſtrenuous aſſertor of the royal prerogative, as he was alſo during the following reign, though he was fully ſenſible of the dangers to which the eſtabliſhed religion was expoſed under the bigotted and gloomy James II. He nevertheleſs refuſed to join in an invitation to the prince of Orange to come to its reſcue; and after the arrival of that prince, he declined ſubſcription to the aſſociation for his ſupport, which was ſigned by the vice-chancellor, and ſeveral heads of colleges in Oxford. When William was ſeated on the throne, he did not ſcruple taking the oath of allegiance to the new government, but he is ſaid to have rejected the offer of ſome perſons in power to place him in one of the ſees vacated by the nonjuring biſhops. His political conduct continued the ſame: he was a violent enemy to toleration, and to any conceſſions for conciliating the ſeparatiſts. In 1693 he engaged in the controverſy reſpecting the doctrine of the Trinity with Dr. Sherlock, and is ſaid to have diſplayed as great a want of Chriſtian charity, as abundance of learning and orthodox zeal. He now began to decline in health; and though his mind was active, yet his bodily powers failed him, and he paſſed the greater part of queen Anne's reign in a ſtate of inaction; but on Sacheverel's trial, he exerted himſelf vigorouſly to procure a lenient ſentence from the judges. When his friends came into power, towards the cloſe of that reign, he was ſolicited to accept the biſhopric of Rocheſter and deanery of Weſtminſter, but he replied, ſuch a chair would be too uneaſy for an old infirm man to ſit in. The queen's deceaſe was conſidered by him as a ſignal of his own approaching diſſolution, "ſince," he ſaid, "that all that was good and gracious, and the very breath of his noſtrils, had made its departure to the regions of bliſs and eternal happineſs." He died in July 1716, at the age of 83, and was interred with much ſolemnity in Weſtminſter Abbey.

Dr. South cannot be regarded as a proper pattern of a Chriſtian miniſter, the follower of the meek and holy Jeſus; though his ſincerity as a true believer of the doctrines of revealed religion has never been doubted. His temper was harſh and unamiable, iraſcible and unforgiving, and his talents for wit and humour led him too frequently to indulge in ill-natured ſarcaſm. His talents were conſiderable, and he is uſually reckoned among the good writers of the time, though he frequently manifeſted a want of taſte in not adapting his wit to ſubjects ſuited to it. He is author of Sermons, in ſix volumes, which have paſſed through many editions. After his deceaſe there appeared his "Opera Poſthuma Latina," and his Engliſh poſthumous works, which conſiſted of three additional ſermons; Travels into Poland, and Memoirs of his Life, in 2 vols. 8vo. Biog. Brit.

South, in *Geography*, a ſhort river of Anne Arundel county, in Maryland, which runs eaſterly into Cheſapeak bay; its mouth is about ſix miles S. of Annapolis city, and is navigable for veſſels of burden ten or twelve miles.

South *Anna*, a branch of North Anna river, in Virginia, which together form Pamunky river.

South *Bay*, a bay in Hudſon's Straits, on the N. coaſt of Labrador, W. of Cape Chidley.—Alſo, an arm of lake Champlain, extending weſterly from its ſouth extremity. Where it unites with the lake, it receives Wood creek from the ſouth.

South *Cape*, a cape at the ſouthern extremity of New Holland. S. lat. 43° 42′. E. long. 146° 56′.

South *Creek*, a river of North Carolina, which runs into Pamlico Sound, N. lat. 34° 54′. W. long. 76° 48′.

South *Downs*, downs of England, in the county of Suſſex, between Brighthelmſtone and Lewes.

South *Downs Sheep*. See Sheep.

South-*Eaſt Bay*, in *Geography*, a bay of the S.E. extremity of Tavia-Poenammoo. S. lat. 46° 45′. W. long. 191° 21′.

South *Eſk*. See Esk.

South *Friar's Bay*, a bay on the S. coaſt of the iſland of St. Chriſtopher; 3 miles E.S.E. of Baſſeterre.

South *Hams*, a tract of land in the county of Devon, England, in the vicinity of Torbay, celebrated for cyder.

South *Haven Point*, a long crooked projection of land on the coaſt of Dorſetſhire, in the Engliſh Channel, which forms one of the points of entrance into Pool harbour.

South *Head*, a cape on the N.E. coaſt of New Holland. S. lat. 24° 2′. W. long. 108° 17′.

South *Hero*. See Hero. North Hero, in 1810, contained 552, and South Hero 826 inhabitants.

South *Iſland*, a ſmall iſland in the Indian ſea, near the E. coaſt of Madagaſcar. S. lat. 17°. E. long. 50° 20′.—Alſo, a ſmall iſland in the ſtrait of Saleyer, near the S. coaſt of the iſland of Celebes. S. lat. 5° 45′. E. long. 120° 51′.—Alſo, a ſmall iſland in the Eaſt Indian ſea, near the S.W. coaſt of the iſland of Bouton. S. lat. 5° 42′. E. long. 122° 50′.—Alſo, a ſmall iſland in the North Pacific ocean. N. lat. 24° 22′. E. long. 141° 20′.

South *Key*, a ſmall iſland in the Spaniſh Main. N. lat. 15° 40′. W. long. 82° 35′.—Alſo, one of the Bahamas, in the Weſt Indies. N. lat. 22° 21′. W. long. 74° 6′.

South *Mountain*. See Blue *Ridge*.

South *Point*, a cape on the S. coaſt of the iſland of Anticoſti. N. lat. 49° 5′. W. long. 62° 35′.—Alſo, a cape at the ſouthern extremity of the iſland of Barbadoes. N. lat. 13°. W. long. 58° 23′.—Alſo, a cape on the S.W. coaſt of Sir Henry Martin's iſland. S. lat. 8° 58′. E. long. 220° 15′.—Alſo, a cape on the S.W. coaſt of the iſland of Fortaventura. N. lat. 28° 1′. W. long. 14° 1′.

South *River*, a river of Antigua, which runs into the ſea, a little to the north of Young Point.—Alſo, a river of Canada, which runs into the St. Lawrence, N. lat. 46° 56′. W. long. 70° 26′.

South *Salem*, a poſt-townſhip of America, in the ſtate of New York, and county of Weſt Cheſter; 50 miles from New York; bounded north by North Salem, eaſt by the ſtate of Connecticut, ſouth by Connecticut and the towns of Pounbridge and Bedford, and weſt by Somers. The whole of this townſhip may be called a good farming country. In 1810, the number of its inhabitants was 1566. This town was formerly called Salem, but its name was altered in 1808. The inhabitants manufacture moſt of their clothing in their own houſes.

SOUTH *Sea*. See PACIFIC *Ocean*.

SOUTH-*Sea Caſtle*, a fortreſs of England, in the vicinity of *Portſmouth*; which ſee.

SOUTH-*Sea Company*. See COMPANY and FUND.

SOUTH-*Sea Tea*, in *Botany*, &c. See ILEX.

SOUTH *Thule*, in *Geography*, a point of land in the South Atlantic ocean, being the moſt ſouthern land diſcovered by navigators. S. lat. 59° 54′. W. long. 27° 45′.

SOUTH-*Weſt Bay*, a bay on the ſouth-weſt coaſt of Tavai-Poenammoo, between Cape South and Cape Weſt.

SOUTH-*Weſt Cape*, a cape on the ſouth coaſt of New Holland, north-weſt of South Cape. S. lat. 43° 37′. E. long. 146° 7′.

SOUTH-*Weſt Point*, a cape on the ſouth-weſt coaſt of the iſland of Anticoſti. N. lat. 49° 25′. W. long. 63° 4′.

SOUTHADLEY, or SOUTH HADLEY, a poſt-town of America, in the ſtate of Maſſachuſetts, and county of Hampſhire, on the eaſt bank of Connecticut river; 12 miles N. of Springfield; incorporated in 1753, and containing 902 inhabitants.

SOUTHAKER LEDGE, a reef of rocks, near the ſouth coaſt of Labrador. N. lat. 50° 5′. W. long. 60°.

SOUTHAM, a ſmall market-town in Southam diviſion of Knighlow hundred, Warwickſhire, England, is ſituated 10 miles from Warwick, 12 from Coventry, and 82 N.W. from London. In Domeſday book the name is written *Sucham*, and the town is there ſaid to contain four hides, with two mills, and woods of one mile in length and half a mile in breadth; all which belonged to the king. Henry III. granted it a weekly market, and an annual fair. The market is held on Mondays, but little buſineſs is tranſacted. The chief ſources of emolument are the two roads which paſs through it: that from Coventry to Banbury, and that from Warwick to London. The pariſh church is a handſome edifice, with a ſpire riſing from a ſquare tower at the weſt end. The population of the pariſh, in the year 1811, was returned as 1007; the number of houſes 165.

Two miles from Southam is the village of Long Itchington, where the earl of Leiceſter magnificently entertained queen Elizabeth, July 9, 1575, in her progreſs to Kenilworth. The village is now ſmall, but appears to have been of conſiderable conſequence at the time of the Conqueſt, and for ſome ſucceeding ages. It was the birth-place of St. Wolſtan, biſhop of Worceſter, in the eleventh century, a man of ſome eminence in the pious chronicles of that period. Beauties of England and Wales, vol. xv. part 2. Warwickſhire, by J. N. Brewer.

SOUTH AMBOY, a town of America, in Middleſex county, New Jerſey, containing, by the cenſus of 1810, 3071 inhabitants. See PERTH-*Amboy*, which contained 815 inhabitants.

SOUTH AMERICA. See AMERICA.

SOUTHAMPTON, or SOUTHTON, an ancient borough, port, and corporate town of Hampſhire, England, is ſeated on a neck of land, which is bounded on the weſt and ſouth by a broad lake-like expanſe, called the Southampton Water, and by the river Itchin on the eaſt. From this peculiarity of ſituation, it has only one approach by land, from the north; and from the ſame cauſe, the firſt buildings of the town appear to have been raiſed at the extreme point of land, and to have progreſſively continued in a line northward, on a ridge of ground between the two waters. Hence the town was ſoon formed by one long ſtreet, flanked and guarded by embattled walls, and ſtrongly fortified gates towards the water on the ſouth, and to the inland country on the north. The preſent Southampton is comparatively a modern town, and originated in the ſuperior eligibility of its ſcite, for commerce, to the ſtation at Bittern, the Clauſentum of the Romans, and the Hamton of the Saxons, &c. The ancient hiſtory, before the Norman conqueſt, applies chiefly to Old-Hampton; but it is almoſt impoſſible to aſcertain when the old town was deſerted, and the new one formed and governed by its own laws. It is evident that Hampton muſt have been a town of conſequence under the Anglo-Saxon dynaſty, as it imparted its name to the whole county, and is ſtill the county town.

Hiſtorical Events.—The origin and name of this town have occaſioned much conjecture and diſſertation. The moſt natural ſuppoſition is, that it was derived from the river *Ant*, or *Anton*, near the ſouthern extremity of which it ſtands. This river, after flowing from the upper parts of the county, and giving appellations to ſeveral places in its courſe, here widens into a conſiderable eſtuary; and, in conjunction with the Itchin, forms the head of the Southampton Water, the ſuppoſed *Antona* of Tacitus. There are indeed thoſe who prefer deducing it from *Ham*, a home or reſidence, with the adjunct *Ton*. Domeſday book and other ancient records, however, clearly favour the former opinion; for in theſe writings it is ſpelt *Hantun*, and *Hantune*. The prefix of *South* evidently aroſe from its relative ſituation to *Northam*. The county itſelf was alſo called *Hantunſcyre*, though its name has been long altered into *Hampſhire*.

It appears from the Saxon Chronicle, that in 873 Hanton was attacked by the Danes, who landed from 33 ſhips; but, after committing many atrocities, they were repulſed and driven to their ſhips. About the year 980 another body of Danes landed here, and ravaged the town and its neighbourhood; and it was ſcarcely 12 years afterwards, that they are recorded to have a third time plundered Southampton, under the command of Sueno of Denmark, and Olaus of Norway.

It does not appear with any certainty, whether the town had been fortified previous to theſe devaſtations; though an eminent antiquary, ſir Henry Englefield, ſuggeſts the opinion, that a *caſtle* was built here by the Saxons, very ſoon after they had achieved a permanent eſtabliſhment in this country. "The peculiar advantages of the narrow and rather high point of land on which Southampton now ſtands," ſays the worthy baronet, "commanding at once the Itchin and Teſt rivers, and very eaſily fortified on the land ſide, could not eſcape their notice; and from the high circular hill, on which the keep of the caſtle formerly ſtood, and the curved line of its yet remaining wall, we have probable grounds for ſuppoſing it to be among the moſt ancient of the Saxon caſtles."

The different aſſaults made on Hanton by the Danes, render it probable that it had very early riſen to ſome importance; and moſt likely from its commerce, to which its ſituation was very favourable. The acceſſion of Canute to the Britiſh ſceptre, however, put a period to the Daniſh ravages in this iſland; and Southampton appears to have become an occaſional reſidence of that ſovereign: for it is here that he is recorded, by Henry of Huntingdon, to have repreſſed the impious flattery of his courtiers by a moſt impreſſive leſſon. They had hailed him as one whoſe royal mandate all nature muſt obey. To put this ſuppoſed omnipotence to the teſt, and to reprove the flattery, he, deſcending the beach, commanded, ſays the hiſtorian, a chair to be ſet for him; in which having ſeated himſelf, he ſaid to the flowing tide, "Thou art under my dominion, and the ground on which I ſit is mine; nor did ever any diſobey my commands with impunity: therefore, I command thee not to wet the clothes or feet of me, thy lord and maſter." But the rude waves, continues the hiſtorian, preſently came up to his royal feet, and daſhed over him; when, ſpringing back, he exclaimed, "Let all the inhabitants of the world know, that the power of monarchs is a vain and empty thing; and that no one deſerves the name of king, but He, whoſe will, by an eternal decree, the heavens, the earth, and the ſea, do obey." Nor would he ever after ſuffer the crown to be put on his head, but cauſed it to be placed on the great crucifix at Wincheſter. And it is worthy of remark, that all the coins of Canute ſeem to give ſanction to this ſtory; as they either repreſent him as wearing a mitre, or a cap, or a triangular covering, ſimilar to that on the coins of St. Edward. See Canute.

Several circumſtances prove, that this town had attained conſiderable importance before the Norman invaſion; though it appears to have ſuffered greatly from the ravages of earl Toſtan. Henry I. is ſuppoſed to have made it a borough by charter; as the "burgeſſes of Southampton" are mentioned in his grants to the canons of the priory of St. Dionyſius, which he had founded. Many privileges were granted to the burgeſſes by king John, who exempted them from toll, paſſage, and pontage, by ſea and land, in fairs and in markets, throughout all his dominions; as well on this ſide the ſea as beyond. By the ſame charter he granted them the port of Portſmouth, in *ferm;* for which, together with the *ferm* of Southampton, they were to pay 200*l.* yearly. The agreement to pay this ſum ſufficiently indicates the opulence and flouriſhing ſtate of the town at that period; which appears to have ariſen principally from the wine trade: and, ſo early as 1215, the merchants of Southampton are recorded to have imported more wine than any others in England, thoſe of London excepted. White or ſweet wines were then moſtly in uſe, and theſe were chiefly imported from Genoa and Venice, by aliens; who were reſtricted to this port by a duty payable to Southampton, even if the wine was landed elſewhere.

In the reign of Henry III. the barons of the Cinque Ports became very troubleſome to the merchants of Southampton, by frequently attaching their perſons, and ſeizing their goods, under pretended reference to ancient grants. The king, being appealed to on this ſubject, iſſued a writ, dated May 14, 1252, commanding the barons to deſiſt from their outrages; and four years afterwards he inveſted the burgeſſes with new privileges, by a very ample charter, dated at Briſtol, July 14, 1256. It appears that Southampton firſt ſent members to parliament in the 23d of Edward I. Conſiderable trade was now carried on between this port and France; and the detention, at St. Valery and Barfleur, of ſome ſhips belonging to Southampton, was in great meaſure the cauſe of the war between this country and France, toward the concluſion of the 13th century.

The trade of this town continued very flouriſhing till the rupture with France in 1338, on account of the refuſal of the ſtates of that kingdom to acknowledge the claims of Edward III. to its throne. The ſame year the mayor and bailiff were commanded, by writ, to cauſe all their ſhips, of 40 tons burthen and upwards, to be victualled, and furniſhed with men at arms, ready to defend the land, in caſe of invaſion. Theſe preparations, however, were made too late. The French, with their allies, the Spaniards and Genoeſe, landed in October, from a fleet of 50 gallies; and, having ſlain all who oppoſed them, entered and plundered the town, and afterwards deſtroyed the greater part of it by fire. Many of the principal inhabitants were, at the ſame time, inhumanly put to death. The invaders did not, however, effect this devaſtation with impunity: ſeveral diſtinguiſhed perſonages of their own party were ſlain, and, among them, the ſon of the king of Sicily. This fatal event interrupted the growing proſperity of Southampton; as many of the merchants were totally ruined, and others afterwards removed to places leſs expoſed to invaſion. In the following year an act was paſſed for rebuilding and ſtrongly fortifying the town; and the king, in a new charter, confirmed all the grants made by his predeceſſors, and inveſted the inhabitants with additional immunities.

In the reign of Richard II. a plan was propoſed, by a rich Genoeſe merchant, for rendering Southampton one of the principal ports of Europe; but the jealouſy of ſome London merchants is ſaid to have defeated the deſign, and to have cauſed the aſſaſſination of the projector.

In July, 1345, the army, which afterwards ſo memorably diſtinguiſhed itſelf on Creſſy's plains, was embarked at this port. That gallant army of Britons alſo, which gained immortal fame at the battle of Agincourt, under Henry V., in 1415, was aſſembled and embarked at Southampton; and it was here that the foul conſpiracy againſt the life of that monarch was timely diſcovered and puniſhed. The principal conſpirators were Richard, earl of Cambridge, grand-father of king Edward IV., lord Scrope of Maſham, and ſir Thomas Grey of Northumberland. They were brought to trial, condemned, and executed in this town. Lord Scrope, who had been a particular favourite of the king, was hanged, drawn, and quartered: the others were beheaded; and their bodies were interred in the chapel of the Domus-Dei, or God's Houſe; as is recorded by an inſcription on a ſtone, erected by a predeceſſor of the preſent earl of Delaware. Hiſtorians differ widely reſpecting the motive to this plot. Some ſay, that the project was ſuggeſted by the court of France; which, terrified at the preparations of Henry, had engaged theſe three noblemen, for the bribe of a million of livres, to murder the king at Southampton; an account which Shakſpeare ſeems to have credited. See his play of Henry V. act ii. ſc. 2.

> "See you, my princes and my noble peers," &c.

With greater probability, however, others appear to think that the conſpiracy was formed originally by the earl of Cambridge, ſecond ſon of the duke of York; who, having eſpouſed the ſiſter of the earl of March, had zealouſly embraced the intereſts of that family, and engaged lord Scrope and ſir Thomas Grey to ſecond his views. See Holingſhed's Chronicle.

The trade of Southampton muſt have been in a very flouriſhing ſtate in the reign of Henry VI.; or we can hardly ſuppoſe that ſo great a man as the lord mayor of London, and keeper of queen Margaret's wardrobe, ſir Thomas Cooke, would have borne the office of cuſtomer of this port.

In the reign of Edward IV., when the feuds between the houſes of York and Lancaſter raged with their utmoſt violence, ſcarcely a day elapſed which was not marked with ſome hoſtilities of the oppoſite parties. That diviſion of ſentiments, with reſpect to the two contenders for the crown, which pervaded almoſt all England, ſubſiſted at Southampton; and at laſt raged with ſuch fury, that a fierce ſkirmiſh enſued between the partiſans of the white and red roſes, in which ſeveral of the inhabitants loſt their lives. The Yorkiſts being at length victorious, the leaders of the Lancaſterian party were made priſoners. Edward was of a temper too jealous and ſevere to pardon ſo great an inſult on his government. Haſtening immediately to Southampton, he commiſſioned Tibetot, or Tiptoft, earl of Worceſter, to ſit in judgment on the priſoners. About twenty of them were tried, condemned, and executed; but the malice of the monarch, not ſatisfied with that infliction, which ought to have cloſed the ſcene of human puniſhment, permitted their breathleſs carcaſes to be impaled, and expoſed in this horrid ſtate to the public gaze: a mean gratification of impotent revenge, uſeleſs as it was unpopular, which brought a deſerved odium on the king, and on Tiptoft, as the miniſter of his vengeance. Leland's Collectanea, i. 502.

Among the number of royal viſitors who have occaſionally honoured Southampton with their preſence, it reckons the emperor Charles V., who, in 1522, embarked here on board the Engliſh fleet, which conveyed him to Spain. We have alſo to mention Edward VI. In the year 1552 this prince, having been attacked by both the meaſles and ſmall-pox, his conſtitution was ſo much weakened, as to render relaxation abſolutely neceſſary. By the advice of his phyſicians, therefore, he made a tour of amuſement through the weſtern and ſouthern parts of his kingdom, attended by 320 ſoldiers, and courtiers and ſervants to the amount of 4000 horſe. Amongſt other places, he viſited Southampton, and was received by the inhabitants with much reſpect, and coſtly preparations. In 1534, Philip, then prince of Spain, but who afterwards reigned as Philip II., landed here, when he came to marry Mary I. queen of England. Queen Elizabeth kept her court here in 1569; and in 1575 granted to the corporation the arms, which are now uſed in the town-ſeal.

Camden, who wrote in the reign of queen Elizabeth, ſays, that the town was, in his time, famous for the number and beauty of its buildings, its affluent inhabitants, and the reſort of numerous merchants. But after this, Southampton appears to have declined in its trade and conſequence; being, in the year 1695, (as Gibſon, in his edition of Camden, obſerves,) "not in the ſame flouriſhing ſtate as formerly: for, having loſt its trade, it has loſt alſo moſt of its inhabitants; and the great houſes of its merchants are now dropping to the ground, and only ſhew its ancient magnificence." Since that time, however, trade has again brought its advantages to Southampton: numerous opulent families alſo have been attracted, by the beauty of its neighbourhood, to ſettle in and around it; and it is at preſent a town of the firſt beauty and conſideration in the weſt of England.

Commerce and Trade.—Southampton has many conſiderable wine, corn, and timber merchants. Hemp, iron, and tallow, from Ruſſia, and tar and pitch from Sweden, are imported. Engliſh iron is brought coaſt-ways from Wales; and coals, lead, and glaſs, are conveyed by the colliers from Newcaſtle. The importations from Portugal are chiefly wine and fruit. To Jerſey and Guernſey 6000 tons of unwrought wool are allowed to be exported annually; great part of which is again returned, manufactured into coarſe knit hoſe. During the laſt war, large quantities of Spaniſh wool were landed here. Contracts for biſcuits for the navy, and bread and clothing for the army, were executed to a conſiderable extent. A ſilk-manufactory employs a number of children. Ship-building is alſo carried on at different docks near the town. At Woodmill, in the neighbourhood, the late Mr. Walter Taylor's curious machinery for the manufacture of blocks and pumps for ſhipping ſtill exiſts; but the chief buſineſs of ſupplying the navy is now transferred to Portſmouth dock-yard. The lateſt bye-laws for the regulation of the port and harbour of Southampton were arranged in an act of parliament, paſſed 43d Geo. III.

The corporation, according to its laſt charter, granted by Charles I., conſiſts of a mayor, a recorder, nine juſtices, a ſheriff, two bailiffs, twenty-four common-councilmen, and as many burgeſſes. All who have paſſed the chair are aldermen. The town, which was made a borough by Henry II., and by king John (or, as others ſay, by Henry VI.) a county in itſelf, is independent of the lord lieutenant and ſheriff of Hampſhire. The mayor is admiral of the liberties, from South-ſea caſtle to Hurſt caſtle, and half ſea over from Calſhot to the Iſle of Wight. There are about 700 voters for the two members in parliament for this place; and not only thoſe who pay ſcot and lot, but out-burgeſſes alſo vote. It may be here obſerved, that ſeveral royal burgeſſes have been enrolled among this corporation: the late prince of Wales, in 1750, at his particular requeſt; the late dukes of York, Cumberland, and Glouceſter; his preſent majeſty; the prince regent; the dukes of York, Kent, Cumberland, Suſſex, and Cambridge; the duke of Wirtemberg alſo, who paſſed through this town immediately after his arrival from the continent.

There are two annual fairs, the principal of which is Trinity fair, held near Chapel Mill, adjoining to the town. It commences on Saturday noon in Whitſun-week, and continues till Wedneſday noon in Trinity-week; but Monday is the chief day of buſineſs, when there is a tolerable ſhow of cattle. The ſenior bailiff preſides during the fair, having a tent, in which he entertains the corporation, and his other viſitants. During the continuance of the fair, no one can be arreſted for debt within its precincts. St. Mark's fair is held above Bar, on the 6th and 7th of May. Three weekly markets, on Tueſday, Thurſday, and Saturday, are well ſupplied with excellent fiſh, poultry, meat, butter, fruit, and vegetables.

The ſalmon taken in the Southampton Water is excellent, though much leſs plentiful than formerly; when it is ſaid to have been neceſſary to ſtipulate in indentures, that apprentices ſhould not be obliged to eat of this fiſh oftener than once a day.

Public Buildings, &c.—Of late years Southampton has been much frequented as a watering-place; for which purpoſe its peculiarly healthful and pleaſant ſituation is extremely favourable. The aſſembly-rooms are ſituated near the weſt quay, and very elegantly fitted up. A theatre was erected here in 1766; but not being found large enough, a new one, on a much more commodious and extenſive ſcale, has ſince been built on the ſcite of St. John's hoſpital.

The population of Southampton, as returned under the act of 1801, was 7913, *viz.* 3390 males, and 4523 females; the number of houſes was 1582. But the return of 1811 ſtated the population at 9617, *viz.* males 4130, and females 5487; the number of houſes 1669.

As already noticed, the northern extremity of the old High-ſtreet is terminated by an ancient fortified gate-houſe, called the Bar-gate. This is a curious ſtructure, and conſiſts of a central arched paſſage, about eighteen yards in length, and four in width. On both ſides of this are two lateral paſſages, or poſtern door-ways. This majeſtic portal was principally built in the reign of Edward III.; and, according to the architecture of that time, it is both machicolated and embattled. On its north front are portrayed two gigantic figures, one on each ſide of the gateway; which are traditionally ſaid to have been intended to repreſent, the one, Aſcupart, or Aſcapard, a terrible giant and mighty warrior; and the other, ſir Bevois, or Bevis, of Southampton, who, according to the popular legends, ſlew him in combat. Over the arches of the gate is the town-hall, which is 52 feet long, and 21 feet wide.

The Caſtle was ſituated on the weſt ſide of the town, but very little of the ancient building itſelf is remaining. Its area was of a form approaching to a ſemicircle, or rather of a horſe-ſhoe; in the ſouthern part of which ſtood the keep, on a very high artificial mount. This keep was circular, but has given place to a ſmaller and more modern round tower, erected with the materials of the former one. The view of the town and the adjacent country from this ſpot is extremely intereſting. The caſtle was purchaſed by the late marquis of Lanſdowne, who made great additions and alterations to it, and fitted it up in a coſtly, but fantaſtic ſtyle.

There were formerly in Southampton ſix pariſh churches: thoſe of Holy-Rood, St. Michael, All-Saints, St. Lawrence, St. John, and St. Mary. But in the reign of Charles II. the pariſhes of St. John and St. Lawrence were united, and the church of the former was taken down: a burying-ground now occupies the ſpot on which it ſtood.

Holy-Rood church has a fine organ, and ſeveral handſome monuments; one of which, by Ryſbrack, to the memory of Miſs Stanley, has an inſcription from the pen of the author of “The Seaſons,” Thompſon. St. Michael's church is the moſt ancient in the town, and has a fine ſlender octangular ſpire, which greatly adds to the beauty of many proſpects: it was erected for a mark or guide to ſhips entering the port. In the north aiſle of the chancel is a handſome monument to the memory of the lord chancellor Wriotheſley; and in the oppoſite aiſle, on the ſouth, is a curious antique font. In this church the mayor is always ſworn into office. All-Saints church is a modern ſtructure, which does honour to the genius of its architect, the late Mr. Revely. St. Mary's and St. Lawrence's churches are not particularly remarkable.

A ſpacious manſion in Porter's-lane, near the ſcite of the Water-gate, diſplays conſiderable antiquity. It has been minutely deſcribed by ſir H. C. Englefield (Archæologia, vol. xiv.), in a “Walk through Southampton,” who conjectures it to have conſtituted a part of the palace occaſionally inhabited by the Saxon and Daniſh ſovereigns. The length of the building in front is 111 feet.

The Domus-Dei, or God's Houſe, is an hoſpital, founded, according to Leland, in the reign of Henry III., by two merchants, brothers, of the names of Gervaſius and Protoſius. “Theſe two brethren, as ther lerned, dwellyd in the very place, where the hoſpitale is now, at ſuch tyme as old Hampton was brent by pyrates; theſe two brethren, for Goddes ſake, cauſed their houſe to be turnid into an hoſpitale for poor folkes, and endowed it with ſome landes.” By a charter of 6 Edw. III., however, it ſeems that Roger Hampton founded it; but at what time is not known. It was given by Edward III. to Queen's college, Oxford, which had been founded by Philippa, his conſort; and to that inſtitution it ſtill belongs. The preſent eſtabliſhment conſiſts of a warden, four aged men, and as many women, who are allowed two ſhillings each, weekly, from the college; and have a yearly donation of coals, under the will of the late Mrs. Fifield, of Southampton.

Among other ancient inſtitutions in this town was a houſe of Grey friars, founded in the year 1240, but of which ſcarcely any remains are now ſtanding; part of its ſcite being occupied by Glouceſter-ſquare; and another part by a building now uſed as a warehouſe, “for the vaſt quantities of Spaniſh wool, which, *by ſtreſs of weather*, are landed here every year.” St. John's hoſpital, for the inſtruction of ſix boys in the woollen manufacture, has been lately given to the poor-houſe by the corporation, with the conſent of the heirs of the founder.

A free grammar-ſchool was eſtabliſhed in Southampton by Edward VI., in an old building in Winkle-ſtreet, now uſed as a carpet-manufactory; from which, many years afterwards, it was removed to its preſent ſituation, an ancient manſion, known by the name of Weſt-Hall. Here are alſo a charity ſchool, a Sunday ſchool, and a ſchool of induſtry; and near the entrance of the town, on the right, is a neat range of alms-houſes, for eighteen poor widows, who are allowed two ſhillings each, weekly, from the produce ariſing from a bequeſt by Robert Thorner, eſq. of Baddeſley, who died in July, 1690.

The environs of Southampton are noted for pictureſque ſcenery, handſome villas, and intereſting objects of antiquity. About one mile north-eaſt of the town is the ſcite of the ancient Clauſentum. The ſituation of this ſtation has been a matter of diſpute among antiquaries, nor was it exactly ſettled till the year 1792, when the Rev. Mr. Warner publiſhed an eſſay to prove it to be at Bittern, and rendered any farther doubt on the ſubject ſuperfluous: moreover, ſome late diſcoveries made there, in the formation of the bridge over the Itchin, and of the road connected with it, have fully confirmed whatever Mr. Warner had previouſly advanced as conjectural. An account of theſe diſcoveries has been publiſhed, with an engraved plan of the ſituation, in the firſt volume of “The Hampſhire Repoſitory.” The time when Clauſentum became a ſtation has alſo been a ſubject of diſpute; but Mr. Warner pronounces it to have been formed under the direction of Veſpaſian, during his continuance in the ſouthern parts of Britain.

In 1804 and 1805 other diſcoveries were made at Bittern, by the late proprietor, Henry Simpſon, eſq. of which a detailed account has been given by ſir H. C. Englefield, bart. in his “Walk through Southampton,” 2d edit.

Immediately facing Bittern, on the weſt ſide, is Bevis-Hill, ſo called from a tradition, that ſir Bevis, the famous knight of Southampton, lies buried under it. It now makes part of the gardens formed by the late earl of Peterborough, and in which his lordſhip was uſed to walk with Arbuthnot and Pope.

About half a mile north of Southampton is Belle-Vue, a handſome building, with highly pictureſque pleaſure-grounds, belonging to Joſiah Jackſon, eſq. Two miles from this town, towards the north-eaſt, is Portſwood Houſe, a manſion of the late Giles Stibbert, eſq. who erected it in 1771, from deſigns by Mr. Crunden, architect. Since then it has been much altered. Seated on an eminence, it commands extenſive and diverſified views of the Itchin river, Southampton Water and town, and much fine wooded ſcenery. In the pariſh of South Stoneham is Wood-Mill, built by the late Walter Taylor, for the manufactory of blocks and pumps for the navy. The improvements made in theſe articles by Meſſrs. Taylor and ſon, have been of great importance in naval tactics. In 1759 theſe gentlemen exhibited ſpecimens of blocks, ſhivers, and pins before the Board of Ordnance, who immediately commiſſioned the inventors to prepare and ſupply all the gun-tackle blocks for the navy. From this time ſeveral improvements were made in the machinery and mechanical formation of blocks, &c. and equal improvements in the conſtruction of ſhip-pumps. By one of theſe, called the double bailing machine, four tons of water may be raiſed in two minutes and a half, and even with or without

out the atmoſphere. (Prints and deſcriptions of theſe machines are publiſhed in the “Hampſhire Repoſitory.”) North Stoneham Park, the ſeat of Mrs. Fleming, is a handſome houſe, in a fine park, the latter of which was laid out by the late Mr. Brown. In the adjoining church is a ſuperb monument to lord Hawke, who died October 17, 1781. See Hawke.

The remains of St. Dionyſius's priory form a pleaſing object from Bittern. They ſtand at the diſtance of two miles from Southampton, on the weſtern ſide of the Itchin, in the grounds which belonged to the late general Stibbert.

At the diſtance of four miles from Bittern, in a ſouthern direction, are the ruins of Netley, or Letley abbey, on the eaſtern bank of the Southampton Water. Their ſituation is very beautiful. The field on which they ſtand commands ſeveral views of the river beneath, equally beautiful, but various according to the ſpot whence they are ſeen. The profuſion of ivy which covers the mouldering walls; the various ſhrubs and trees that now occupy the ſcite and walls of the church; the fragments of architecture lying around in diſorderly ruin; and the elegance of thoſe few parts which have yet eſcaped deſtruction; combine to form a ſcene which contemplation cannot leave without reluctance. The founder of this abbey, it is believed, was Henry III., who took a certain number of monks from the abbey of Beaulieu, and placed them at Netley, about the year 1229. The monks were of the Ciſtercian order, and the houſe itſelf was dedicated to the Virgin Mary and St. Edward. The ſcite of Netley abbey, with all the buildings, was, at the diſſolution, granted by Henry VIII., in the twenty-eighth year of his reign, to ſir William Paulet, afterwards marquis of Wincheſter: they next became the property and reſidence of the earl of Hertford; and ſince then were inhabited by the marquis of Huntingdon. The whole is at preſent the property of lady Holland, widow of the late ſir Nathaniel Dance Holland, bart. who has a life-intereſt in them by virtue of her marriage with her former huſband, the late Mr. Dummer, who purchaſed them of Henry Clift, eſq. The principal parts of Netley abbey that remain, are the walls of the church, the kitchen, and the refectory. Theſe are in a ſtate of ruin, but diſplay ſuch elegancies of architecture, as convince us, that the fabric muſt have been originally of great beauty. On the ſhore, at a ſhort diſtance from the abbey, ſtands a fort, or ſmall caſtle, called Netley caſtle, in a dilapidated ſtate, which appears to have been erected by Henry VIII. at the time of his building Cowes and Hurſt caſtles. The paſſage by water to the Iſle of Wight, about fifteen miles diſtant, is delightfully pleaſant.

As natives of Southampton, who have rendered themſelves eminent, we cannot omit to mention the names of Nicholas Fuller, a learned divine, born in 1557, who died in 1622-3; Dr. Iſaac Watts, born in July 1674, who died in 1748; and Richard Pococke, a diſtinguiſhed traveller, and biſhop of Meath, born in 1704, who died in 1765. See accounts of theſe under their reſpective heads.

Southampton lies S.W. from London, at a diſtance of ſeventy-four miles, by the way of Baſingſtoke.

“A Walk through Southampton,” by ſir Henry Engleſield, bart. 8vo. 1805, an intereſting and truly rational eſſay on the antiquities of Southampton and Clauſentum. “The Southampton Guide;” “A Companion in a Tour round Southampton,” 12mo. 1809; “A Viſit to Netley Abbey,” 2d edition, all by Mr. John Bullar, a ſchoolmaſter of Southampton, are uſeful and intereſting topographical volumes, and contain much original information. “The Southampton Guide,” 18th edition, by T. Skelton, is a well-digeſted eſſay on the hiſtory, &c. of the town and of objects in its vicinity. In the Beauties of England, vol. vi. is a copious account of the town and county, by J. Britton and E. W. Brayley.

Southampton, a county of Virginia, between James's river and North Carolina, containing, by the cenſus of 1810, 13,497 inhabitants, of whom 6406 are ſlaves.

Southampton, a town of Maſſachuſetts, in the county of Hampſhire, ſeparated from Eaſt Hampton by Pawtucket river; about 9 miles S.W. from Northampton. It was incorporated in 1753, and in 1810 contained 1171 inhabitants.

Southampton, or *South Hampton*, a townſhip of New Hampſhire, in Rockingham county, on the ſouth line of the ſtate, which ſeparates it from Maſſachuſetts; 16 miles S.W. of Portſmouth. It was taken from Hampton, incorporated in 1742, and contains 427 inhabitants.

Southampton, a poſt-townſhip of New York, in Suffolk county, on the S. ſide of Long iſland; 100 miles E. of New York; bounded N. by Riverhead and Southold, E. by Eaſt Hampton, S. by the Atlantic ocean, and W. by Brookhaven. Its length E. and W. is about 23 miles, and its medial breadth 4½ miles. The ſoil is light and ſandy on the W. and N., but fertile in the S. and E. It is well wooded with pine, oak, walnut, &c. and ſupplies New York with large quantities of cordwood for fuel. The land requires manure, but with good management yields tolerable crops of grain and graſs. Fiſh is much uſed for manure. In 1810 this townſhip contained 3899 inhabitants, including 61 ſlaves, and 475 electors. By means of Sagg-harbour, which is a port of entry in the N.E. corner of this townſhip, it carries on a ſmall trade.

Southampton, a townſhip of Pennſylvania, in Bucks county, containing 739 inhabitants.—Alſo, a townſhip in Franklin county, containing 1060 inhabitants.—Alſo, a townſhip in Bedford county, with 932 inhabitants.—Alſo, a townſhip in Somerſet county, having 455 inhabitants.

Southampton, or *South Hampton*, a townſhip in the eaſtern part of Nova Scotia, in Halifax county, formerly called Tatmagruche; 35 miles from Onſlow.

Southampton, or *South Hampton*, a poſt-town of New York, in Geneſee county; 486 miles from Waſhington.

Southampton *Water*, or *Triſſanton Bay*, a bay of the Engliſh Channel, on the coaſt of Hampſhire, extending from about three miles above Southampton to the channel that ſeparates the Iſle of Wight from the continent. N. lat. 50° 48′. W. long. 1° 7′. See Southampton.

SOUTH BOSTON, a ſmall town in Virginia, in Halifax county, on the N. ſide of Dan river.

SOUTH BRANCH House, a ſtation of the Hudſon's Bay Company, in North America, ſituated on the E. ſide of Saſkaſhawen river.

SOUTH BRIMFIELD, a townſhip of the Maſſachuſetts, in Hampſhire county; 80 miles W. of Boſton; incorporated in 1762, and in 1810 containing 645 inhabitants.

SOUTHBROUGH, a ſmall townſhip in the eaſtern part of Worceſter county, Maſſachuſetts, incorporated in 1727, and in 1810 containing 926 inhabitants; 30 miles W. by S. from Boſton.

SOUTH BRUNSWICK, a townſhip of New Jerſey, in Middleſex county, containing 2332 inhabitants.

SOUTHBURY, a town of Connecticut, in New Haven county, containing 1413 inhabitants.

SOUTH CAROLINA. See Carolina.

SOUTH EAST, a poſt-townſhip of New York, in the S.E. corner of Ducheſs county; 18 miles E. of Weſt Point; its extent is about ſix miles ſquare; it is bounded on the S. by Weſt Cheſter county, E. by Connecticut, N. by

N. by the town of Patterſon, and W. by the town of Carmel. The face of the country is rocky, mountainous, and hilly, but the ſoil is in general good, and adapted to graſs. It is well watered, and affords tolerably good crops of grain and fruits. It abounds with iron-ore of good quality. And the river Crotan, which runs through it, affords excellent mill-ſeats. "Joe's" hill or mountain lies near the centre of this town, and extends to Connecticut. Here are five natural ponds, the largeſt, called Peach-pond, being about two miles long and one wide. The population conſiſts of 1887 perſons, and here is one meeting-houſe. Their domeſtic looms produce 21,000 yards of cloth.

SOUTH-END, a hamlet in the pariſh of Prittlewell, hundred of Rochford, and county of Eſſex, England, is ſituated on the acclivity of a well-wooded hill, at the mouth of the Thames, nearly oppoſite to Sheerneſs, forty-two miles eaſt from London. Within the laſt twenty years this place has obtained ſome repute for ſea-bathing; and though previouſly but little known, has been ſince advancing to importance. Some reſpectable lodging-houſes have been erected for the accommodation of viſitors; and alſo an aſſembly-room. At a ſmall diſtance from the hamlet is a ſtone, placed as a boundary mark of the extenſion of the juriſdiction of the corporation of London over the river Thames, in the eaſtern direction. The village of Prittlewell is built on the declivity of a hill, on the ſummit of which is the pariſh church, a large and reſpectable edifice, the tower of which ſerves as a land-mark to veſſels ſailing into the Thames. About a quarter of a mile north of the church was a priory of Cluniac monks, founded in the reign of Henry II. Beauties of England, Eſſex, vol. iii.

SOUTHERN, THOMAS, in *Biography*, a dramatic writer, is ſaid to have been born at Stratford-on-Avon, about the year 1662, though others aſſume that he was a native of Dublin, and educated at the univerſity there till his eighteenth year, when he came to England. He was entered of Pembroke college, Oxford, in 1680, and ſoon after compoſed a tragedy, entitled "The Perſian Prince, or Loyal Brother," which was acted in 1682. He took up his reſidence at the Middle Temple in 1683, and in the following year another play compoſed by him was acted and publiſhed. When James II. came to the crown, he rewarded Southern for his loyalty in defending his cauſe, when his excluſion from the throne was warmly, or indeed violently agitated, by giving him a captain's commiſſion in the troops intended to oppoſe the landing of the prince of Orange. When his military ſervices became of no account, he returned to his dramatic career, and wrote ſeveral pieces, both in tragedy and comedy, from which he drew a liberal ſubſiſtence. Though Southern does not rank with the higheſt of our dramatic geniuſes, yet he was capable of deeply intereſting the paſſions. His beſt pieces were "Iſabella," and "Oroonoko:" the latter, formed upon one of Mrs. Benn's novels, was ſaid to have been taken from a real ſtory. Southern was apt to mix ſcenes of low and indecent comedy with his tragic ſcenes, but they are ſo managed that they may be eaſily ſeparated, and leave pieces which are occaſionally viewed with applauſe. He lived to a great age, and bore a very reſpectable character. He died in 1746, at the age of 84. His plays were publiſhed collectively by T. Evans, in 3 vols. 12mo. Biog. Brit.

SOUTHERN *Hemiſphere*. See HEMISPHERE.

SOUTHERN *Ocean*. See OCEAN.

SOUTHERN *Sign*. See SIGN.

SOUTHERN *States*, in *Geography*, a denomination comprehending the following ſtates of America; *viz*. Maryland, Virginia, Kentucky, North Carolina, Teneſſee, South Carolina, and Georgia, bounded N. by Pennſylvania. The ſtates above-mentioned contain, by the cenſus of 1810, 3,246,455 inhabitants, including 1,099,523 ſlaves. The principal productions of this diſtrict of the Union are, tobacco, rice, indigo, wheat, corn, cotton, tar, pitch, turpentine, and lumber; and in this diſtrict is fixed the permanent ſeat of the general government, *viz*. the city of *Waſhington*, which ſee.

SOUTHERNWOOD, in *Botany* and the *Materia Medica*. See ARTEMISIA.

SOUTHFIELD, in *Geography*, a townſhip of America, in the ſtate of Maſſachuſetts, and S.E. corner of Berkſhire county; bounded S. by the Connecticut line, containing 147 inhabitants.—Alſo, a townſhip of New York, and the capital of Richmond county, on the S. ſide of Staten iſland; 12 miles S. of New York; comprehending an extent along the ſea, and at the Narrows, of about eighteen miles in length. The ſurface is diverſified, and the land of various qualities. The ſouth part is level, and fit for farming. Here is a tract of natural meadow, around the Great Hills, being a ſmall bay, noted for its dams. Here is a very extenſive ſhad-fiſhery at the Narrows, on the E., within half a mile of which is the plain called "Old Town," which was fortified by the early inhabitants, for defence againſt the Indians. The whole population of this town in 1810 was 1007, with 97 electors. The "Narrows, (which ſee,) leave an opening for the united waters of the Hudſon and Eaſt rivers to communicate with the ocean, 1905 yards wide. On the weſt ſhore are erected the various military works, deſigned for the protection of the trade of New York, and for military defence againſt naval foes. Theſe conſiſt of ſeveral forts and batteries, erected by this ſtate ſince the year 1807, at a very conſiderable expence. Fort Richmond is the principal work, being formed of ſtone, and well ſupplied with all the apparatus and means of defenſive warfare. The telegraph, for ſpeedy communication with New York, ſtands on the high grounds in the rear of fort Richmond.

SOUTH GEORGIA. See *New* GEORGIA.

SOUTH HEMPSTEAD, a poſt-townſhip of New York, in Queen's county, on the S. ſide of Long iſland, 22 miles nearly S.E. from New York. It is bounded N. by North Hempſtead, E. by Oyſter bay, S. by the Atlantic ocean, and W. by Jamaica. This townſhip has the greateſt aggregate population of any in the county, and there are ſeveral ſmall villages, the largeſt of which is of the ſame name with the town. Although it has ſome ſmall ſtreams of water, it principally depends upon tide-mills. The land is generally under good cultivation. The whole population in 1810 was 5804, and at this time it had 445 ſenatorial electors. Rockaway beach on the ſea-ſhore is much frequented in ſummer for ſea-bathing, and the various pleaſures of fiſhing, ſhooting, &c. Game is very plentiful.

SOUTHILL, a pariſh in the hundred of Wixamtree and county of Bedford, England, is ſituated about four miles diſtant from Biggleſwade, nine miles from Bedford, and forty-three N. from London. In ancient records it is called South-Yevel. The manor is the property of lord Ongley, who alſo holds the manor of Stanford, or Stamfordbury, in this pariſh. The monks of Warden abbey had a manor here in 1369, called Gatelin's Bury. Sir George Byng, a naval officer of eminence in the reigns of queen Anne and George I., purchaſed an eſtate and ſettled in this pariſh. In 1721 he was created a peer, by the title of baron Byng of Southill, and viſcount Torrington. He died in 1733, and lies buried in the pariſh church. His unfortunate ſon, admiral John Byng, who was ſhot by ſentence of a court-martial, March 14, 1757, was born and interred at Southill. He is generally conſidered to have fallen a victim to the violence of party. There is an inſcription in the church to his memory, written, it may be thought, with too much aſperity for ſo ſacred a place. There are alſo ſeveral other inſcriptions in memory of other branches of the family. The preſent lord Torrington ſold his eſtate at Southill, in 1795, to Mr. Whitbread, who left it to his ſon, Samuel Whitbread, eſq. M.P. lately deceaſed. This manſion, which is called Southill-Houſe, ranks among the firſt in the county. It was built about the year 1795, by Holland the architect. The internal decorations are very elegant. Over the doors of ſome of the principal rooms are ſubjects in baſſo-relievo of animals by Garrard, and paintings of game by Gilpin. In the billiard-room is a collection of Garrard's models of ſheep and cattle. Over the book-caſes, in the library, are portraits of the principal clerks in Mr. Whitbread's brewery; and over the chimney-piece, that of Mr. Whitbread, ſen. placed there by his ſon, with this modeſt and appropriate motto, "Nobis hæc otia fecit."

The pariſh of Southill was incloſed by an act of parliament, paſſed in 1797, and was then computed to contain 2600 acres. The population return of the year 1811, ſtated this pariſh (including the hamlets of Broom and Stamford) to contain 185 houſes, and 1024 inhabitants. Lyſons's Magna Britannia, Bedfordſhire, 4to. 1806.

SOUTHOLD, or South-hold, a poſt-townſhip of New York, in Suffolk county, compriſing the N.E. part of Long iſland, bounded N. by Long iſland Point, ſoutherly by the waters that ſeparate it from the towns of Eaſt Hampton and Southampton, and W. by Riverhead. The extent of Southold from W. to E., where it terminates in a point, excluſive of the iſlands, is twenty-two miles, and its greateſt width three miles. In 1810 its population was 2613, including 30 ſlaves, and it then had 306 electors. Southold town has a ſtreet five miles long, in which are the poſt-office, a meeting-houſe, and two ſchool-houſes, with 160 families; 100 miles E. of New York.

Southold, a townſhip of Upper Canada, in Suffolk county, W. of Yarmouth, and bounded on the S. by lake Erie.

SOUTH HUNTINGTON, a townſhip of Pennſylvania, in Weſtmoreland county, containing, in 1810, 1656 inhabitants.

SOUTHING, in *Navigation*, the difference of latitude a ſhip makes in ſailing to the ſouthward.

SOUTHINGTON, in *Geography*, a townſhip of America, in Connecticut, and county of Hartford; 20 miles S.W. of Hartford, containing 1807 inhabitants.

SOUTH KINGSTON, a townſhip of Rhode iſland, in Waſhington county, on the W. ſide of Narraganſet bay, containing 3560 inhabitants.

SOUTH-MOLTON. See Molton, *South*.

SOUTHWALLS, a town on the S. coaſt of the iſland of Pomona. N. lat. 58° 40′. W. long. 3° 3′.

SOUTHWARK, commonly called *The Borough*, a town of Surrey, England, alſo a ſuburb of the city of London, and generally regarded as part of that vaſt metropolis. It is, however, completely ſeparated from London by the river Thames, which at this place is 915 feet acroſs; and over which a bridge was conſtructed anterior to the Norman conqueſt. Southwark occupies an area of about one mile and three quarters from eaſt to weſt, by one mile in an oppoſite direction. Nearly the whole of this extent is now covered with houſes, public edifices, and ſtreets, whilſt the bank of the river is occupied by numerous warehouſes, manufactories, timber and coal-yards, glaſs-houſes, &c. The Borough is alſo noted for its number of hop-warehouſes. On the eaſt it is bounded by the pariſh of Rotherhithe, on the ſouth by that of Newington-Butts, on the weſt by Lambeth, and on the north by the river Thames. For accounts of each of which, ſee the reſpective words.

Ancient Hiſtory.—Although part of the preſent diſtrict was probably occupied by ſome Roman villas during the dominion of the Romans in Londinium, yet there is no evidence of its having been a ſtation, or military poſt. Indeed, it was moſt probably at that time a marſhy tract of land. By the Saxons it was called *Suth*, or "South Work," in reference to ſome military work or fortification, bearing that aſpect from London: it was alſo called the Borough, or Burg, probably for the ſame reaſon. It was anciently a diſtinct corporation in itſelf, and was governed by its own bailiffs; but in conſideration of the inconveniencies ariſing from the eſcape of malefactors from the metropolis into this place, it was, in 1327, granted by Edward III. to the corporation of London, on payment of 10*l.* annually. It was then called the *village* of Southwark; it was afterwards ſtyled the *bailiwick* of Southwark, and the mayor and commonalty of London appointed the bailiff. This power, however, not being ſufficient to remedy the evil, a more intimate connection was thought neceſſary; and in the reign of Edward VI. it was united to the city of London, at the earneſt and inceſſant requeſt of the citizens to the lord protector, who was at length prevailed on to grant it; perhaps induced to comply by the conſideration of 647*l.* 2*s.* 1*d.* paid for the charter. It was formed into a 26th ward, by the title of "Bridge Ward Without;" and 500 marks more were paid for certain privileges, antecedently enjoyed by the archbiſhop of Canterbury, the abbot of Bermondſey, the priors of St. Mary Overy's, or Charles Brandon, duke of Suffolk. In conſequence of this, it was ſubjected to the lord mayor of London, who has ſince appointed the ſteward and bailiff. Southwark, however, being divided into two parts, this is to be underſtood only of the diviſion called the *Borough Liberty*, which conſiſts of three of the pariſhes belonging to the town, with the greater part of a fourth pariſh. For the city diviſion, the lord mayor, by his ſteward, holds a court of record every Monday at the ſeſſions-houſe on St. Margaret's Hill in this borough, for all debts, damages, and treſpaſſes, within the limits of his juriſdiction. To this ward of Bridge Without, which is not repreſented in the court of common-council, the ſenior alderman, or father of the city, as he is called, is always removed, as to an honourable ſinecure, which exempts him from the fatigues uſually incurred in the other twenty-five wards. The other diviſion of Southwark is called *The Clink*, or *The Manor* of Southwark, and is ſubdivided into the great liberty, the guildhall, and the king's manor; for each of which ſubdiviſions a court-leet is held, where the conſtables, ale-conners, and fleſh-taſters, are choſen, and other buſineſs of that kind tranſacted. This diviſion is in the juriſdiction of the biſhop of Wincheſter, who, beſides a court-leet, keeps here a court of record on the bank-ſide near St. Saviour's church, by his ſteward, or bailiff, for pleas of debt, for damages, and treſpaſſes. Court-leets are alſo kept at Lambeth, Bermondſey, and Rotherhithe, three diſtricts adjoining to the Borough.

The firſt time that Southwark is mentioned in hiſtory, is on the occaſion of earl Goodwin's ſailing up the river to attack the royal navy of fifty ſhips, lying before the palace of Weſtminſter. This was in 1052; when, we are told, he went *ad Suthwecree*, and ſtaid there till the return of the tide.

Although the borough of Southwark has ſo long been a ward a ward of the city of London, it ſtill retains the privilege of ſending two members to parliament, as it has done ever ſince the 23d Edward I.; but it is not aſcertained when it firſt ſent repreſentatives. The right of election is in the inhabitants paying ſcot and lot, amounting to about 3200.

The things moſt worthy of note in the borough-town of Southwark, properly ſo called, are the churches, the hoſpitals, and the priſons.

The pariſhes are St. George the Martyr, St. Olave, (part of this pariſh is in the city of London,) St. John Horſelydown, St. Saviour, (commonly called St. Mary Overy's,) St. Thomas, and Chriſtchurch: theſe pariſhes were found, in 1811, to contain 12,217 houſes, and 72,119 inhabitants; *viz.* 33,611 males, and 38,508 females. The families chiefly employed in agriculture were 116, and thoſe occupied in trades, manufactures, and handicraft, 10,510.

Churches.—The pariſh church of St. George the Martyr is ſituated a little to the ſouth of the Marſhalſea. The original edifice was of very ancient foundation, and belonged to the abbey of Bermondſey, to which it was given, in 1122, by Thomas Arderne. Being in a very ruinous ſtate, the pariſhioners obtained an act of parliament for taking down the old church, and erecting another; in conſequence of which the preſent ſtructure was begun in 1734, and finiſhed in 1736. In the old church was interred Edward Cocker, the celebrated arithmetician; and the infamous biſhop Bonner, who died miſerably in the Marſhalſea in 1569, is ſaid to have been buried in the church-yard, under the eaſt window.

St. Olave's church is ſituated in Tooley-ſtreet, near the ſouth end of London-bridge. The original edifice is mentioned as early as 1281, but the date of its erection is unknown. Part of this old church having fallen down in 1736, an act was obtained to rebuild it, and the preſent ſtructure was finiſhed in 1739.

Eaſtward of St. Olave's is the pariſh of St. John Horſelydown, corruptly ſo called from Horſe-down having been originally a grazing-ground for horſes. St. John's is one of the fifty new churches ordered by act of parliament to be built in the metropolis, and was finiſhed in 1732, when this diſtrict was ſeparated from St. Olave's, and conſtituted a diſtinct pariſh.

St. Saviour's church, commonly called St. Mary Overy, originally belonged to a nunnery founded by a female, prior to the Norman conqueſt, and endowed by her with the profits of the ferry acroſs the river Thames at this place before the erection of London-bridge. This houſe was afterwards converted into a college for prieſts, by whom the firſt bridge over the Thames was built of wood, and kept in repair, till they were enabled, by the munificence of benefactors, to ſupply its place by another of ſtone. In 1106 the college was transformed into a priory of canons regular; but theſe were ſcarcely ſettled, when the biſhop of Wincheſter brought in ſecular canons in their ſtead. The revenues of this priory, at its ſurrender in 1539, were valued at 624*l.* 6*s.* 6*d.* *per annum.* On its ſuppreſſion, the inhabitants of Southwark purchaſed the church belonging to it, which was by charter appropriated to the joint uſe of the pariſhioners of St. Mary Magdalen and St. Margaret, by the name of St. Saviour's. This church is built upon the plan of a cathedral, though of ſmaller dimenſions. Part of the original architecture is perceived in the interior, near the weſt front of the church; as all the reſt of the fabric exhibits the ſtyles in uſe between the 13th and 16th centuries. The tower, ſtanding in the centre, riſes in three ſtories, the walls finiſhing with battlements, and being adorned at the angles with turrets and pinnacles. It was from this tower that Hollar took his celebrated views of London, both before and after the great fire in 1666.

This church has three chapels: *viz.* our Lady's, or the New Chapel, at the eaſt end of which is run out a ſmall monumental chapel, and which, after this edifice became parochial, was let for upwards of 60 years, by the churchwardens, for the purpoſe of a bake-houſe; St. John's, now the veſtry, on the north ſide of the choir; and St. Mary Magdalen's, on the ſouth ſide. In our Lady's chapel is a grave-ſtone, ten feet in length, on which was formerly a border, and a figure in braſs of a biſhop in his pontifical habit; it is ſuppoſed to cover the remains of the celebrated William of Wykeham, biſhop of Lincoln, and afterwards of Wincheſter, who died in 1395. Eaſtward of the altar is the monument of Lancelot Andrews, biſhop of Wincheſter, who died in 1626, aged 71. His effigy, in full proportion, habited as a prelate of the order of the Garter, lies on a tomb of black and white marble. At his feet are his arms, within a garter, between two ſmall figures of Juſtice and Fortitude. Here alſo is a pleaſing mural monument, from a deſign of Mr. Soane, to the memory of Abraham Newland, eſq., late caſhier to the bank of England, who was interred here November 28, 1807. In the north aiſle is a curious monument, with a ſtatue for Gower, one of the earlieſt Engliſh poets, and a benefactor of this church, to the rebuilding of which he contributed about the year 1400. On the wall are painted three female figures, crowned with ducal coronets, repreſenting Pity, Mercy, and Charity. See "The Hiſtory and Antiquities of the Church and Pariſh of St. Saviour," by Concanen and Morgan, 1 vol. 8vo, 1795.

St. Thomas's church ſtands on the ſouth ſide of St. Thomas's-ſtreet. The original church, being old and ruinous, was taken down, and rebuilt in 1702.

The pariſh of Chriſtchurch was taken out of that of St. Saviour, and was originally part of the diſtrict called the liberty of Paris Garden. The firſt church was erected at the expence of Mr. John Marſhall, of Southwark, and finiſhed in 1671; when he endowed it with an eſtate of 60*l.* *per annum*, towards the ſupport of the miniſter. This edifice, however, in conſequence of the badneſs of the foundation, ſoon became ſo ruinous, that, in 1737, Mr. Marſhall's truſtees applied to parliament for power to rebuild it, with the ſum of 2500*l.*, which had accumulated in their hands from the truſt; and obtained an act for that purpoſe. The preſent ſtructure was accordingly erected. It ſtands on the weſt ſide of the road leading from Blackfriars-bridge.

For the hoſpitals in and near the borough of Southwark, ſee *St. Thomas's* HOSPITAL, *Guy's* HOSPITAL, and *Magdalen* HOSPITAL.

Here we may mention ſome other charitable eſtabliſhments in the vicinity of Southwark. The Aſylum is a foundation for preſerving friendleſs and deſerted girls under twelve years of age from the danger of ſeduction and proſtitution. This excellent charity was ſet on foot by the well-known magiſtrate of Bow-ſtreet, ſir John Fielding. The firſt female children were admitted in July, 1758; and they are inſtructed in ſuch a manner as to render them moſt uſeful to ſociety. This building ſtands at an angle, formed by the meetings of the Weſtminſter-road from the Borough to the Stone's-End, and the direct road to Kennington and Vauxhall.

A little farther on the north ſide of the Weſtminſter-road is a neat modern edifice, called the Freemaſons' Charity-School, appropriated for female children from five to ten years of age; though no child who has not had the ſmall-pox, or who has any defect in her ſight or limbs, or is weak or ſickly, can be admitted. Every child applying for admiſſion, muſt produce a certificate from the maſter and wardens of the lodge in which her father was made a maſon, with a certificate of the marriage of her parents. Sixty girls are maintained and educated in this benevolent inſtitution, which owes its origin to the philanthropic mind of the late chevalier Bartholomew Ruſpini, of Pall-Mall.

To the ſouthward of this, and on the ſcite of the Dog and Duck tea-gardens, is a noble edifice, the new Bethlehem hoſpital, which coſt about 150,000*l.* in building. The edifice is large, commodious, and admirably adapted to its deſtination. It is intended to accommodate 400 patients, and has very recently been completed from the deſigns of James Lewis, eſq., architect. It was commenced in 1812, is about 580 feet in length, and is built chiefly with brick, having ſtone dreſſings, a bold portico in the centre, and a dome. About twelve acres of garden ground, &c. attach to this hoſpital, where ſome of the patients are allowed to exerciſe. Among the important improvements and reformations of the preſent time, is the humane and rational ſyſtem of managing inſane patients, that has been very recently adopted; and in the further improvement of which the Engliſh legiſlature is now engaged. See *Bethlehem* HOSPITAL.

At the point of conflux of the London, Weſtminſter, and Blackfriars-roads, we find an extenſive range of buildings for the protection and ſupport of the indigent blind, maintained, like the other inſtitutions that we have mentioned, by voluntary contributions. The unfortunate objects are taught to manufacture baſkets, clothes-lines, and ſaſh-cord, which are ſold at the ſchool. See BLINDNESS.

On the right-hand ſide of the London-road ſtands the building belonging to the Philanthropic Society, incorporated in 1806. See *Philanthropic* SOCIETY.

Near Cuper's bridge is eſtabliſhed the Refuge for the Deſtitute. The object of this moſt benign and excellent charity is to provide a place of refuge for perſons diſcharged from priſon, or the hulks, unfortunate and deſerted females, and others, who, from loſs of character, or extreme indigence, cannot procure an honeſt maintenance, though willing ſo to do. They are engaged in uſeful trades and manufactures ſuited to their ſexes; and as an incitement to good conduct, a certain portion of their earnings is ſet apart, and allowed them, if diſcharged with credit to themſelves.

Priſons, &c.—At the end of the Borough High-ſtreet is St. Margaret's Hill, the ſcite of the ancient church of the ſame name; which, being forſaken on the union of the pariſh with St. Saviour's, was converted into a ſeſſions-houſe and priſon, ſince removed to Mill-lane, and called the Borough compter. The whole has lately been rebuilt, but has nothing worthy of particular notice. In the front, facing Blackman-ſtreet, which is a continuation of the High-ſtreet, the huſtings for the election of repreſentatives for this borough are uſually erected. On the oppoſite ſide of the ſtreet was the Tabard Inn, which was the reſidence of the abbots of Hyde, in Hampſhire, whenever buſineſs or their parliamentary duty required their preſence in the metropolis. This was the houſe celebrated by Chaucer as the place of rendezvous for pilgrims repairing to Becket's ſhrine at Canterbury; and the very building deſcribed by him exiſted till 1676, when it was burnt, with the ſeſſions-houſe, and other contiguous edifices. When rebuilt, it was ignorantly called The Talbot, under an idea that this was the ſame with Tabard; and by that appellation it ſtill continues to be known.

On the north ſide of Tooley-ſtreet, next to the Thames, is the Bridge-houſe, a foundation which ſeems to be coeval with London-bridge; having been uſed as a ſtore-houſe for ſtone, timber, and other materials employed in its repairs. It is under the ſuperintendance of two officers, called bridge-maſters, who are elected by the livery of London. Below the Bridge-houſe, on the banks of the Thames, ſtood the inn of the abbot of Battle. The ſpot, ſtill called Battle-bridge, was thus named from a bridge over a water-courſe flowing out of the Thames, built and repaired by this prelate, on whoſe ground it was ſituated. In the front of this manſion were the gardens belonging to it; the recollection of whoſe embelliſhment is yet perpetuated by the Maze, and the Maze-pond.

On the eaſt ſide of Blackman-ſtreet is the Marſhalſea, a court of law and a priſon, originally intended for the determination of cauſes and differences between the king's menial ſervants, and under the controul of the knight-marſhal of the royal houſehold. It had particular cognizance of murders and other offences committed within the king's court. To this place alſo, perſons guilty of piracies and other offences on the high ſeas are committed, though the offenders are tried at the Old-Bailey, in London. The priſon, which contains about ſixty rooms, is too ſmall, and much out of repair. In 1377 it was broken open by a mob of ſailors, and four years afterwards by Wat Tyler's followers. It eſcaped, however, in the riots of 1780, though the King's Bench, the Borough priſon, and the Clink, were all at that time the objects of popular fury. See COURT *of Marſhalſea.*

The county-gaol and houſe of correction is ſituated in Horſemonger-lane, at the ſouth-eaſt end of Blackman-ſtreet. This gaol, which has been recently built, is excluſively for the county of Surrey. It was rendered remarkable in the year 1802, when colonel Edward Marcus Deſpard, and ſix of his aſſociates, were hanged upon a platform on the top of the gaol, being convicted of high treaſon, upon the evidence of an accomplice. The heads of theſe wretched perſons were ſevered from their bodies, and held up to the view of the ſpectators, numbers of whom fainted at the ſight.

At the ſouth-weſt end of Blackman-ſtreet is the priſon of the King's Bench, a place of confinement for debtors, and for all perſons ſentenced by that court to ſuffer impriſonment. It conſiſts of one large pile of brick buildings, comprehending 224 rooms. The ſouth centre has a pediment, under which is a chapel. The place is ſurrounded by a brick wall about thirty feet high, defended by *chevaux de friſe;* without which the marſhal, or keeper of the priſon, has very handſome apartments. Priſoners in any other gaol may remove here by habeas corpus. The liberties, or *rules,* as they are termed, extend about three miles round the priſon; and the right of reſiding in any part of them may be purchaſed by debtors at the rate of ten guineas for the firſt hundred pounds, and about half as much for each ſucceeding hundred pounds, of the ſums for which they are in cuſtody. Day-rules, of which three may be obtained in every term, may be purchaſed for four ſhillings and two-pence the firſt day, and three ſhillings and ten-pence the others. Each perſon muſt alſo give good ſecurity to the marſhal. The day-rules, however, only authoriſe the priſoner to go out on the days for which they are bought. The inſide of this extenſive priſon reſembles a ſmall town, from the circumſtance of its being furniſhed with butchers' ſhops, bakers', green-ſtalls, &c.; while the throng of people conſtantly at play give it the appearance of a fair. See COURT *of King's Bench.*

The Clink was a gaol at Bankſide for the confinement of ſuch as ſhould "brabble, fray, or break the peace on the ſaid bank, or in the brothel-houſes." This priſon ſtill exiſts, and has been repreſented as a filthy, noiſome dungeon. The biſhop of Wincheſter's ſteward tries pleas of debt, damages, or treſpaſs within the Clink liberty for any ſum.

Palaces, Theatres, &c.—Contiguous to the priory of St. Mary Overy, and nearly at the foot of London-bridge, was ſituated the biſhop of Wincheſter's palace. The houſe was built about 1107, by William Gifford, at that time biſhop of Wincheſter, upon a piece of ground belonging to the prior of Bermondſey. Biſhop Beaufort, uncle to Henry VI., on being created a cardinal on his return from France, was met by the mayor and aldermen of London, and conducted by them in great pomp to this his palace in Southwark. During the civil wars this place was for ſome time a priſon for the royaliſts. Sir Francis Doddington and ſir Kenelm Digby were both confined here at once; and here the latter wrote his book on "Bodies, &c." Wincheſter houſe was ſold by parliament, in 1649, to Thomas Walker of Camberwell, for 4380*l.* 8*s.* 3*d.* with the park included. The buildings, in the old plans of London, appear to have formed two court-yards, with various offices, &c. The ſouth ſide was bounded by beautiful gardens, ſtatues, fountains, &c.; the north ſide by the river; the eaſt by the monaſtery of St. Saviour; and the weſt by the Bear-gardens. The greater part of the building, which is ſtill remaining, is occupied by corn-lofts, warehouſes, &c.

What is now denominated Bankſide, was formerly a range of dwellings, licenſed by the biſhops of Wincheſter "for the repair of incontinent men to the like women," and denominated the Bordello, or ſtew-houſes. Theſe brothels were ſubject to various laws and regulations enacted by parliament; among which we find the following: "that they were to be kept ſhut on Sundays and holidays; that no married women ſhould be received into them; that no man ſhould be drawn or enticed thither; and that no ſtew-holder ſhould keep any woman who had on her the venereal diſeaſe, then termed the 'perilous infirmity of burning,' or ſell bread, ale, fiſh, or any victuals." (See BURNING.) In 4 Rich. II. theſe houſes, then belonging to ſir William Walworth, lord mayor of London, were rented of him by froes, or bawds, of Flanders, and were deſtroyed by the Kentiſh rebels under Wat Tyler. It ſeems probable, that reſentment for the perſonal injury ſuſtained on this occaſion may have had its ſhare, as well as loyalty, in producing the action for which Walworth is particularly diſtinguiſhed. The ordinances reſpecting theſe houſes were, however, again confirmed by Henry VI.; but in 1506 they were for ſome time uninhabited. It was not long, however, before they were again opened, that is, ſo many as were permitted; "for whereas," ſays Fabian, "before were eighteen houſes, from thenceforth were appointed to be uſed but twelve only." Theſe privileged ſtews had ſigns painted on the fronts, which looked towards the Thames; as the boar's head, the croſs keys, the gun, the cardinal's hat, &c. Stow relates, that the women who frequented them were forbidden the rites of the church, and excluded from Chriſtian burial, unleſs they were reconciled to it before they died. A plot of ground, called the Single Women's church-yard, at ſome diſtance from the pariſh church, was therefore appointed for their interment. In 1546, theſe ſtews were ſuppreſſed by Henry VIII.; and it was proclaimed by ſound of trumpet, that they ſhould be no longer privileged and uſed as a common brothel, but that the inhabitants were to keep good and honeſt rules, as in other places of this realm.

Not far from St. George's church ſtood the magnificent palace of Charles Brandon, duke of Suffolk, the deſerving favourite of Henry VIII. After his death, in 1545, it devolved to the king, who eſtabliſhed here a royal mint. At that time it was called Southwark Place, and in great meaſure preſerved its dignity. Edward VI. once dined in it. His ſiſter and ſucceſſor preſented it to Heath, archbiſhop of York, as an inn or reſidence for him and his ſucceſſors whenever they repaired to London. As to the mint, it became a ſanctuary for inſolvent debtors; and at length, becoming the peſt of the neighbourhood, by giving ſhelter to villains of all ſorts, it arouſed the attention of parliament; which, by the ſtatutes 8 & 9 Will. III. and 9 & 11 Geo. I. entirely took away its abuſed privileges.

In the pariſh of Chriſtchurch, near the water on the Bankſide, ſtood Paris Garden, one of the ancient playhouſes of our metropolis. Ben Jonſon is reproached by Dekker, an envious critic, with his ill ſucceſs on the ſtage; and, in particular, with having performed the part of Zuliman at Paris Garden. It ſeems to have been much frequented on Sundays. This profanation, however, was at length fully puniſhed by a dire accident which befel the ſpectators in 1582; when the ſcaffolding ſuddenly fell, and multitudes of people were killed or miſerably maimed. The omen ſeems to have been accepted; for in the next century the manor of Paris Garden was erected into a pariſh, and a church founded under the name of Chriſt's church.

Near this ſcene of amuſement were the Bear-garden, and a place for baiting of bulls. "Herein (Stow tells us) were kept bears, bulls, and other beaſts to be baited, as alſo maſtives in ſeveral kennels nouriſhed to bait them. Theſe bears and other beaſts are there kept in plots of ground ſcaffolded about for the beholders to ſtand ſafe." This was at that time an amuſement for perſons of the firſt rank: our great Elizabeth cauſed the French ambaſſadors to be carried to this theatre, to divert them with theſe bloody ſpectacles.

Not far from the ſpot in which the Bear-garden was, near Bankſide, is Globe-alley; ſo called from that theatre which flouriſhed in 1603, with a licence under the privy ſeal, granted by James I. to Shakſpeare, Fletcher, Burbage, Heming, &c. and where the plays of our inimitable Shakſpeare were firſt repreſented. See PLAYHOUSE.

About ten years after it had been licenſed, "by the negligent diſcharging of a peal of ordnance, cloſe to the ſouth ſide thereof (ſays Stow), the thatch took fire, and in a very ſhort ſpace the whole building was quite conſumed, and no man hurt, the houſe being filled with people to behold the play of Henry VIII." In the following ſpring it was rebuilt; but in the next reign it fell into diſrepute. See an intereſting account of and diſquiſition on the Globe theatre and the old playhouſes in the Gentleman's Magazine for 1816, and in Malone's and Chalmer's accounts of the Engliſh ſtage, in the third volume of the edition of Shakſpeare's Plays, 1813.

St. George's Fields, which have borne their ſhare of celebrity in ancient times, having frequently been the ſcene of grandeur and cavalcade, and ſometimes the rendezvous of rebellion and tumult, and which, leſs than half a century ago, were mere marſhes, and only paſſable to foot-paſſengers, are now almoſt covered with newly-erected buildings, from the ditch at the end of Great Surrey-ſtreet, or Burrow's buildings, to the Fiſhmonger's alms-houſes, in one direction; and from the Marſhalſea priſon to the late Dog and Duck, in the other direction; with ſeveral irregular indentions in its circumference. Where the principal roads meet, an Obeliſk was erected in 1771, in honour of Braſs Croſby, eſq. the patriotic lord mayor of London, who had been confined in the Tower, with alderman Oliver, for the conſcientious diſcharge of his magiſterial duty. An inſcription on one ſide of it expreſſes the cauſe of its erection; and thoſe on the other three ſides mark the diſtances from Fleet-ſtreet, London and Weſtminſter bridges. This obeliſk is about a mile from the one at the end of Bridge-ſtreet, on the city ſide of Blackfriars-bridge.

One of the new bridges for which acts of parliament have recently been obtained, is deſigned to croſs the Thames from the bottom of Queen-ſtreet, Cheapſide, to Bankſide, and to be called the Southwark bridge: it is alſo propoſed to form a handſome ſtreet from the foot of it to St. Margaret's Hill.

In Union-ſtreet, northward of the mint, is Union-hall, a handſome ſtructure, appropriated to the purpoſes of a police office for the Borough.

At the foot of Blackfriars-bridge is a large range of buildings, which were erected by a company of gentlemen ſome years ſince, with a view of counteracting the impoſitions too common in grinding of corn. There was a ſteam-engine, made by Meſſrs. Boulton and Watt, of Birmingham, which turned ten pair of ſtones, each pair grinding nine buſhels of corn every hour, without intermiſſion by day or night; beſides which, it gave motion to the various apparatus for hoiſting and lowering the corn and flour out of and into the barges; for fanning the corn, to keep it free from impurities; and for ſifting and dreſſing the meal from its firſt ſtate, till perfectly cleared for the uſe of the baker. The accidental burning of theſe mills, on the 3d of March 1791, forms a kind of epoch among the remarkable fires that have occurred in and about the metropolis. Such a body of light and heat was ſcarcely ever known as diſplayed itſelf on this occaſion. The fire broke out about ſix in the morning, and burnt with ſuch amazing rapidity, that the houſe of the ſuperintendant, at one corner of the building, was all that eſcaped the fury of the flames. Out of 4000 ſacks of flour, 36 only were ſaved. The front, &c. remained ſome years unrepaired; but the whole range has lately been formed into a row of handſome private houſes.

On the oppoſite ſide is Albion-place, containing the houſe belonging to the Britiſh plate-glaſs manufactory. This company, incorporated in 1773, carries on a flouriſhing concern here, and at their works at Ravenhead, in Lancaſhire.

On the weſt ſide of Blackfriars-road, near the bridge, is the building occupied a few years ſince by ſir Aſhton Lever's muſeum, removed thither from Leiceſter-ſquare, when, by lottery, it became the property of Mr. Parkinſon. This aſtoniſhing collection of ſubjects of natural hiſtory here experienced the moſt mortifying neglect, till, in 1806, it was finally diſperſed by public auction, in a ſale which laſted 40 days. The premiſes are now occupied by the Surrey Inſtitution, one of thoſe uſeful eſtabliſhments which are intended to promote the diffuſion of ſcience, literature, and the arts, and which was opened March 25, 1808.

Surrey chapel, on the eaſt ſide of Blackfriars-road, is a large octagonal building, for the uſe of Proteſtants of the Methodiſt perſuaſion, under the Rev. Mr. Rowland Hill, a rather eccentric preacher, but a moſt worthy man. It is calculated to hold nearly 5000 perſons, and can ſeldom contain the numbers that flock to it for admittance. The organ, by Elliot, has been much admired for its ſweetneſs of tone, as well as for its extenſive powers: it has, in fact, been aſſerted, that on the performance of one of the hymns deſcriptive of thunder, many of the congregation have fainted.

The Royal Circus is ſituated at the end of Blackfriars-road, near the Obeliſk, before-mentioned. It originated in a ſubſcription in favour of Mr. Hughes, a riding-maſter, who, in conjunction with the late Mr. Dibdin, exhibited ballets, pantomimes, and horſemanſhip, with conſiderable ſucceſs. Through ſome diſagreement this houſe was ſeveral years ſhut up; but was at length opened by Meſſrs. Jones and Croſs. In Auguſt 1805, the whole building was conſumed by fire, but in the courſe of the following year it was rebuilt in a manner ſuperior in taſte and elegance to the former ſtructure. Under the management of Mr. Elliſton, of Drury-lane theatre, the exhibition of horſemanſhip was aboliſhed; and, with the new appellation of the Surrey theatre, this place has acquired more of the ſpirit and character of the legitimate drama. Bray's Hiſtory and Antiquities of Surrey, 3 vols. folio. Deſcription of Surrey in the 14th vol. of the Beauties of England, &c. by F. Schoberl, 1813. Picture of London, 1815. Pennant's Account of London. Oldfield's Repreſentative Hiſtory of Great Britain, 6 vols. 8vo. 1816. See the article LONDON, in a preceding part of this work; alſo LAMBETH, SURREY, NEWINGTON-BUTTS, and ROTHERHITHE.

SOUTHWARK, *Eaſt*, a townſhip of Pennſylvania, in Philadelphia county; containing 7264 inhabitants.

SOUTHWARK, *Weſt*, a townſhip of Pennſylvania, in Philadelphia; containing 6443 inhabitants.

SOUTH WASHINGTON, a town of North Carolina, on the N.E. branch of Cape Fear river, which is navigable ſo far for boats; 36 miles from Winnington.

SOUTHWELL, or SUELL, called *Suthell*, an ancient market-town and pariſh in the wapentake of Thurgarton, and county of Nottingham, England, is 14 miles N.E. of the county-town, and 138 N.N.W. from London. It is ſeated on a gentle eminence, on the bank of the river Greet, celebrated for its red trout. Some writers have conjectured it to have been the Ad Pontem of the Romans, but without ſufficient grounds of authenticity. There is, however, an ancient intrenchment in the vicinity. Its modern appellation is ſaid by Dugdale to owe its origin to a ſpring or well to the ſouthward of the church. The government of the town is divided between the clergy, called prebends, and laity, or juſtices: the former exerciſing authority over one part of the town, called the Prebendage, including the collegiate church and its property; and the latter over the other part, called the Burgage, which comprehends all that part between the market-place and the river. The cuſtos-rotulorum, and the magiſtrates for this juriſdiction, who are nominated by the archbiſhop of York, and conſtituted by a commiſſion under the great ſeal, hold their ſeſſions both at Southwell and at Scrooby, and perform all other judiciary acts diſtinct from the county. A collegiate church is ſaid to have been founded here by Paulinus, archbiſhop of York, about the year 630, and this ſeems to have been always under the patronage of the prelates of that ſee, though the firſt grant we meet with of this is by king Eadwy to archbiſhop Oſcytel, in 958. It appears by Domeſday book, that here were ſeveral canons at the Conqueſt, but the number of ſixteen was not ſettled till the next century, and ſo many continue to this day; for though the then archbiſhop ſurrendered this church to king Henry VIII., 1540, yet he eſtabliſhed the chapter ſhortly after, and endowed it with the greateſt part of its ancient poſſeſſions; and though it ſuffered again in the time of Edward VI., it was reſtored by Elizabeth, and confirmed by James I.

The collegiate church is a large, ancient, and very curious edifice. It conſiſts of a nave, with two aiſles, two towers at the weſt end, a tranſept, a choir with aiſles, and a chapter-houſe. The extreme length from E. to W. is 306 feet, width of tranſept from N. to S. 121 feet, and breadth of nave 59 feet. The oldeſt parts, the nave, weſtern towers, and tranſept, are commonly ſaid to be of Saxon architecture, built during the ſhort reign of Harold; but we ſhould rather refer them to an age after the Norman conqueſt. The choir, with its ſplendid ſtone ſtalls, as well as the very beautiful chapter-houſe, are all about the date of Edward III.'s reign. Between the nave and the choir is a ſtone ſcreen of very elaborate workmanſhip, with niches, pilaſters, pinnacles, crockets, &c. A large alabaſter altar-tomb is raiſed in this church to the memory of archbiſhop Sandys. In the church-yard was a college for chanting-prieſts. Here is now a free-ſchool, under the care and government of the chapter, who chooſes the maſter. Two fellowſhips and two ſcholarſhips in St. John's college, Cambridge, are in the preſentation of Southwell college. Theſe were founded by Dr. Keton, canon of Saliſbury, in the time of Henry VIII. The archbiſhops of York formerly had a palace here, ſituated on the ſouth ſide of the church-yard, and which was once a large and elegant building: the ruins of it are ſtill extenſive, but diveſted of all its architectural forms. Some windows, and a circular chimney of the age of Henry VIII., yet remain, and being deeply overſhadowed with ivy and emboſomed in trees, add much to the romantic beauty of the place. The archiepiſcopal parks were once four in number; or, according to Leland, three; but they have been divided and encloſed ſince the deſtruction of the palace in the civil war of Charles I. During thoſe unhappy times the king was often here; and the town frequently experienced the fate of war. Southwell, according to the population return of 1811, contained 561 houſes, occupied by 2674 perſons: though not a place of much trade, it has a reſpectable market on Saturdays, and an annual fair. Dickinſon's Hiſtory and Antiquities of Southwell, 4to. 1787. At the end of Dugdale's Hiſtory of St. Pauls, is an account of the church of Southwell. Thoroton's Hiſtory, &c. of Nottinghamſhire, by Throſby, in 3 vols. 4to. 1790.

SOUTH WEST Point, a poſt-town of Teneſſee, at the confluence of the Clinch with Teneſſee river, where a block-houſe is erected; 40 miles from Knoxville.

SOUTHWICK, a townſhip of America, in the ſtate of Maſſachuſetts, and county of Hampſhire; 110 miles from Boſton: incorporated in 1770, and containing 1229 inhabitants.

SOUTHWIST. See Wist.

SOUTHWOLD, a market-town in the hundred of Blything, and county of Suffolk, England, is ſituated on an eminence overlooking the German ocean, but nearly ſurrounded by the river Blyth, which here diſcharges itſelf into the ſea. Its ancient name was Sudwald, or Southwood. It is diſtant from Ipſwich 36 miles N.E., and 105 miles, in the ſame bearing, from London. The manor was an ancient donation from Alfric, biſhop of the Eaſt Angles, to the abbey of Bury St. Edmunds, by which it was held for the victualling of the monks. From the dimenſions of this manor given in Domeſday Survey, Gardner, in his Hiſtory of Dunwich, calculates that the ſea has ſince gained upon this coaſt one mile, one furlong, and nineteen perches. In the tenth year of Henry IV. Southwold was exempted from the payment of any cuſtoms or tolls, for their ſmall boats, paſſing in or out of the river or port of Dunwich. Henry VII., in conſideration of the induſtry and good ſervices of the men of Southwold, made the town a free burgh or corporation, to be governed by two bailiffs, a recorder, and twelve aldermen; to whom and the commonalty he gave his lordſhip, called Queen's demeſne revenues, and alſo the privilege of admiralty, for the annual payment of 14*l.* He further granted them exemption from all dues and cuſtoms payable to Dunwich, and conferred on the town the rights of a haven, which probably cauſed the denomination of the port of Dunwich to be changed to that of Southwold. Henry VIII. not only confirmed all his father's grants, but added many gifts, franchiſes, and immunities. Theſe royal favours gave great encouragement to the trade and navigation of the town, of which the fiſhery conſtituted a material part, being carried on by merchants, who annually fitted out veſſels for taking cod and other fiſh in the North ſea. The herring-fiſhery off their own coaſt was highly conducive to the proſperity of the town. Though in ſome degree affected by the diſſolution of religious houſes, yet Southwold retained an extenſive trade, and ſurpaſſed all the neighbouring towns in ſhipping and commerce. But the greateſt calamity that ever befel it was on the 25th of April, 1659, when a fire, heightened by a violent wind, conſumed, in the ſpace of a few hours, the town-hall, market-houſe, priſon, granaries, warehouſes, and 238 dwelling-houſes, and other buildings, with the principal part of the goods and merchandize of the inhabitants; the total loſs exceeded 40,000*l.* to the ruin of more than 300 families, ſo that the town never recovered its former importance. About a century afterwards the commerce was conſiderably improved: the entrance to the haven being ſubject to be choaked up, an act of parliament was obtained for repairing and improving it: one pier was erected on the north ſide of the port in 1749, and another on the ſouth in 1752. The eſtabliſhment of the Free Britiſh Fiſhery, about the ſame time, alſo contributed to the proſperity of the town; two docks were conſtructed, and various buildings erected for making nets and depoſiting ſtores. A chapel appears to have been built here in the reign of king John, by the prior and monks of Thetford, who were patrons of the church of Reydon, to which Southwold was then only a hamlet. This chapel being deſtroyed by fire about 220 years after its erection, the preſent edifice was erected about 1460, and was then made parochial, and in 1751 was ſeparated from Reydon, and made a diſtinct curacy. The length of this fabric is 143 feet; the width 56 feet: it has two aiſles, ſeparated from the nave by ſeven arches, and ſix pillars of elegant workmanſhip. The tower, about 100 feet in height, is a fine piece of architecture. Though Southwold has many good houſes, it has no other building worthy of particular notice. On the cliffs are two batteries, one of which is a regular fortification, with a parapet and ſix guns; the other has but two. On a hill called Eye-hill, veſtiges are ſeen of an ancient encampment, which Gardner conjectures to have been a camp of the Danes, when they invaded the country in 1010. The population of Southwold in the year 1811 was returned to parliament as 1369; the houſes 326. A reſpectable market is held on Thurſday; and here are two annual fairs.

Southwold-bay, commonly called Sole-bay, is celebrated as the ſcene of a moſt obſtinate and ſanguinary engagement in 1672, between the combined fleets of England and France on one ſide, and the Dutch on the other. The former, conſiſting of 101 ſail, were lying in this bay on the 28th of May, when the Dutch fleet, compoſed of 91 men of war, 54 fire-ſhips, and 23 tenders, commanded by the famous De Ruyter, bore down upon them ſo unexpectedly, that many of the ſhips were obliged to cut their cables, that they might get out more expeditiouſly, and arrange in order of battle. The French bore but a ſmall part in the engagement, which was vehemently conteſted by the Engliſh and Dutch during the whole of the day, till at nine at night, the Dutch veſſels being dreadfully ſhattered, were obliged to retreat, and the Engliſh, having equally ſuffered, were not in a condition to purſue them. In this conflict the Engliſh loſt ſix ſhips, and about 2003 men killed and wounded. The Dutch loſt only three ſhips; their loſs in men muſt have been very great, but the States forbade the publication. Hiſtorical Account of Dunwich, &c. 4to. 1754. Beauties of England and Wales, vol. xiv. Suffolk, by F. Schoberl.

SOUTO MAJOR, a town of Portugal, in the province of Beira; 14 miles N.W. of Pinhel.

SOUTOUX, an Indian village of Louiſiana, on the W. ſide of the Miſſiſippi river, oppoſite to the Nine-mile Rapids, and 28 above Riviere de la Roche. N. lat. 41° 50′.

SOUTSONE, a town of Little Bucharia; 150 miles W.N.W. of Caſhgar.

SOUVERABO, a town of Africa, on the Grain Coaſt.

SOUVERINHO, a town of Portugal, in the province of Alentejo; 17 miles W.N.W. of O Crato.

SOUVIGNY, a town of France, in the department of the Allier, and chief place of a canton, in the diſtrict of Moulins; 6 miles W. of Moulins. The place contains 2659, and the canton 10,022 inhabitants, on a territory of 340 kiliometres, in 11 communes.

SOUZA, LOUIS DE, in *Biography*, a Portugueſe writer, born at Santarem, was ſon of a man of rank, governor of the caſtle of St. George de la Mina. He was educated to the profeſſion of arms, and ſerved firſt in the order of Malta, when he was taken priſoner by the Turks. After recovering his liberty, he ſerved with the troops in America and the Eaſt Indies. After this he married, but the loſs of a child and other afflicting circumſtances impreſſed both him and his wife with a ſpirit of devotion, and they took the religious habit in the Dominican order, De Souza changing his baptiſmal name of Manuel for that of Louis. He had already acquired a good ſhare of literature, and had written an elegant preface to the Latin poems of Falcone. He was, therefore, choſen to write the hiſtory of his order in Portugal in the vernacular tongue, of which he printed the firſt volume, folio, in 1623. From his papers two other volumes were printed after his death. He was author alſo of the "Life of Dom. Bartholemew, one of the Martyrs," printed in 1619, and of which a French tranſlation has been given; and "A Hiſtory of John III. King of Portugal," which has not been publiſhed. De Souza is accounted one of the beſt writers of his country.

SOW, in *Geography*, a river of England, in the county of Stafford, which runs into the Trent, 3 miles E. of Stafford.—Alſo, a river of England, in the county of Stafford, which runs into the Avon, 4 miles N. of Warwick.

SOW, in *Zoology*. See SUS, HOG, and SWINE.

SOW, in the *Iron-works*, the name of the block or lump of metal they work at once in the iron-furnace. The ſize of theſe ſows of iron is very different, even from the ſame workmen and the ſame furnace. Theſe furnaces having ſand-ſtone for their hearths and ſides, up to the height of a yard, and the reſt being made of brick, the hearth, by the force of the fire, is continually growing wider; ſo that if it at firſt contains as much metal as will make a ſow of 6 or 7 cwt., at laſt it will contain as much as will make a ſow of 20 cwt.

SOW, in *Ancient Military Language*, a kind of covered ſhed, fixed on wheels, under which the beſiegers filled up and paſſed the ditch, ſapped or mined the wall, and ſometimes worked a kind of ram.

Some ſay it derived its name from the ſoldiers lying under it cloſe together, like pigs under a ſow; though another reaſon is given for that appellation, namely, its being applied to digging and rooting up the earth. The former was alluded to by the counteſs who defended the caſtle of Dunbar againſt king Edward III., when ſhe threatened, that unleſs the Engliſhmen kept their ſow better, ſhe would make her caſt her pigs. Camden, who mentions this circumſtance, ſays, "the ſow is yet uſed in Ireland." Two machines, the one called the boar and the other the ſow, were employed by the parliamentarians in the ſiege of Corfe-caſtle, Dorſetſhire. The ſow was ſimilar in conſtruction to the *Cattus*, (which ſee), cat-houſe, or cat, ſo called becauſe under it ſoldiers lay in watch, like a cat for its prey; ſome of theſe cats had crenelles and chinks, from whence the archers could diſcharge their arrows; theſe were called caſtellated cats.

SOW, or *Hop-ſow*, in *Agriculture*, a name applied in ſome diſtricts, as in the county of Eſſex, to a tool or contrivance for pulling or forcing up hop-poles out of the earth in which they have been fixed. It is conſtructed of a ſtout ſtrong tapering ſort of pole or ſtake, about three inches in diameter, and five feet in length, to which, at the diſtance of nearly a foot from the lower or larger end, is firmly fixed and clinched a ſmall bar of iron, about half an inch ſquare, and a foot long, which is bent nearly in the middle, ſo as to form an acute angle with the ſtake, four inches or rather more being open at the upper end of it, which make a ſort of hook with the ſtake, by which the pole is graſped, and the inſide of the iron bar being raiſed and roughed by the ſmith, ſomewhat in the manner of teeth, when fixed upon the lower end of the hop-pole, near the ſurface of the ground, is enabled to bite and hold it faſt; when, by the lower end of the tool being made to reſt upon the ground on the oppoſite ſide of the hop-pole to that on which the workman ſtands, and the whole acting as a lever, is readily, and with facility, made to raiſe or lift the hop-pole out of its ſocket in the ſolid ground, though it may be ſet a foot or more into it.

It is a ſimple, cheap, and effective invention for accompliſhing this neceſſary purpoſe in hop-management. In the county of Kent, the implement employed in the ſame intention is denominated a *hop-dog;* and thoſe in other hop diſtricts have moſt probably the ſame name given to them. See HOP.

SOW-*Bread*, in *Botany*, &c. See CYCLAMEN.

The roots of the round-leaved ſow-bread with a purple under-ſide, have a nauſeous, acrid, biting taſte: by drying their acrimony is abated; nevertheleſs, when taken internally, they betray a great degree of irritating power. Dried and powdered they have been given in doſes of a drachm, and found to operate as a ſtrong, inflammatory, but ſlow cathartic. The juice is ſaid to purge when applied externally to the belly in ointment; and the juice or bruiſed root to be of great efficacy for ſoftening and diſcuſſing indolent hard tumours. The flowers are of a different nature, and have not been uſed medicinally; and the uſe of the roots is now, among us, in a great meaſure, laid aſide. Lewis.

SOW-*Thiſtle*. See SONCHUS.

The common ſow-thiſtle has been much recommended by authors as a refrigerant and attenuant. It was preſcribed by many of the old phyſicians in ſtranguries, and other diſorders of the urinary paſſages; and ordered externally in cataplaſms, in all kinds of inflammations.

SOW-*Thiſtle, Downy*. See ANDRYALA.

SOW *and Pigs*, in *Geography*, rocks in the German ſea, near the E. coaſt of England, and the county of Northumberland; 3 miles E.N.E. of Blythe. N. lat. 55° 9′. W. long. 1° 12′.—Alſo, rocks on the coaſt of Maſſachuſetts, in Buzzard's bay, lying off the S.W. end of Catahank iſland.

SOWAGEPOUR, a town of Hindooſtan, in Bahar; 27 miles N.N.W. of Hajypour.

SOWERBÆA, in *Botany*, was ſo named, by the writer of the preſent article, in commemoration of his friend and fellow labourer, Mr. James Sowerby, F.L.S., &c. an excellent botaniſt and artiſt, to whoſe accuracy and acuteneſs of obſervation he acknowledges himſelf to have been often indebted, in the courſe of his own botanical ſtudies and publications; and to whom various other authors have been no leſs obliged.—Sm. Tr. of Linn. Soc. v. 4. 218. Ait. v. 2. 231. Brown Prodr. Nov. Holl. v. 1. 285.—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Spathaceæ*, Linn. *Aſphodeli*, Juſſ.

Gen. Ch. *Cal.* Common Sheath of ſeveral membranous, permanent ſcales; the outer ones ovate, concave; inner in many fine ſegments. *Cor.* Petals ſix, ovate, equal, permanent; three of them interior. *Stam.* Filaments ſix, ſhort, broad, flattened, obtuſe, three of them barren; anthers three, on the three filaments oppoſite to the interior petals, oblong, each of two linear ſpreading lobes, of one cell, ſlightly connected a little above their baſe only, divaricated at each end, permanent. *Piſt.* Germen ſuperior, roundiſh, with three furrows; ſtyle thread-ſhaped, permanent; ſtigma ſimple. *Peric.* Capſule roundiſh, three-lobed, of three cells and three valves; the partitions from the centre of each valve. *Seeds* one or two in each cell, angular, rough.

Eſſ. Ch. Sheath of many valves. Petals ſix. Stigma ſimple. Anthers with diſunited cells. Three alternate filaments barren. Seeds nearly ſolitary.

1. S. *juncea*. Ruſh-leaved Sowerbæa. Sm. Tr. of Linn. Soc. v. 5. 159. t. 6. Ait. n. 1. Br. n. 1. Ker in Curt. Mag. t. 1104. Andr. Repoſ. t. 81.—Native of Port Jackſon, New South Wales. Firſt cultivated by Meſſrs. Lee and Kennedy, in 1792. It is a hardy greenhouſe herbaceous plant, flowering in the early part of ſummer, and eaſily increaſed by parting its fibrous perennial *roots* in the ſpring, planting them in peat-earth. The whole *herb* is ſmooth, deſtitute of a ſtem. *Leaves* numerous, radical, ſheathing, erect, linear, acute; channelled above; ſemi-cylindrical beneath; their ſheaths crowned internally with a ſimple membranous *ſtipula*, like that of a graſs. *Stalk* ſolitary, erect, ſimple, above a foot high, taller than the leaves, bearing a rather denſe umbel, of copious, elegant, roſe-coloured, ſcentleſs *flowers*, much reſembling thoſe of ſeveral ſpecies of *Allium*, on capillary partial *ſtalks*, each of which has, as Mr. Brown remarks, a joint under the flower. The *capſules* become pendulous as they ripen, each encloſed in its ſhining, ſcarcely altered, *corolla*. *Anthers* yellow.

The authority of Mr. Brown, who has examined this plant in its native country, induces us to correct ſome of our ideas concerning it, which indeed had never been very firmly impreſſed in our mind. The cells of the *anthers* prove to be ſimple, and though they firſt open at the top, by a ſeeming pore, they ſoon ſplit all the way down, by a furrow, which gives them the appearance of being two-celled. Though nearly ſeparate, therefore, through their whole length, theſe cells together conſtitute but one *anther*, as in the SCITAMINEÆ, ſee that article, whoſe cells are ſtill further disjoined. The genus of *Sowerbæa* is, nevertheleſs, perfectly diſtinct, though nearly related to *Allium*. The herb, when bruiſed, has no peculiar ſcent.

SOWING, in *Agriculture*, the act of ſcattering, or putting the ſeeds of grain, plants, &c. on or into the ground, in order to their producing crops. See SEED.

With regard to the period or ſeaſon of ſowing, or putting crops into the ſoil, it is remarked, that the moſt proper and advantageous ſeaſon for ſowing or ſetting ſuch as poſſeſs the habit, or are capable of perfecting and ripening their ſeed or produce in the ſame year, is that of ſome of the more early ſpring months, according as they are more forward or late in their kinds, and the climate more mild, or the contrary; while, on the other hand, ſuch as are, from the peculiarity of their nature or habits, incapable of completing their vegetation in the ſame year, the moſt favourable period will be ſome of the more early autumnal months, according to the differences of their habits, and the variations of climate and ſeaſon: as by theſe means, in the former caſe, the ſeeds, grains, or roots, become perfectly evolved, and the radicles of the young plants firmly eſtabliſhed in the ſoil, and capable of ſuſtaining themſelves againſt the hot ſeaſon ſets in, which is to bring them to maturity; and, in the latter, the ſeeds have attained ſuch a ſtate of growth, and ſo far fixed their roots in the ground, as to be capable of ſupporting themſelves, without ſuſtaining much injury from the ſeverity of the winter ſeaſon, and conſequently advance with greater rapidity in their vegetation in the ſpring, in order to perfect their ſeed by the heat of the ſummer ſeaſon.

And it is further ſtated, on the authority of lord Orford, that the practice is adviſed of ſowing certain ſorts of grains and ſeeds, and alſo of ſetting particular kinds of roots, at much earlier periods in the ſpring than is commonly had recourſe to by the farmer. Thus, it is ſaid, by putting barley into the ground in the beginning of February, great advantage has been ſuppoſed to have been derived in the forwardneſs and fineneſs of the grain. But againſt this method it has, however, been ingeniouſly ſuggeſted by Dr. Darwin, that as much moiſture, with or without ſubſequent froſt, is more liable to deſtroy the embryo in its very early ſtate in the ſeed, than after it has ſhot out roots and a ſummit, and thus acquired ſome habits of life, ſuch early ſowing muſt, in ſome caſes, be practiſed with caution. But that ſuch an objection cannot be brought againſt the early autumnal ſowings.

The crops of autumn-ſown wheat ſhould be conſtantly put into the ground in the latter end of September, or beginning of the following month; but the former, if poſſible. And the ſpring-ſown kinds ſhould not be later than the end of March; as, when later ſown, they never ripen well. And with oats and barley crops, February, March, and April, are the ſeaſons uſually had recourſe to. But from grain ſeeds and roots requiring ſuch different lengths of time in arriving at maturity, the particular period at which each ſort of grain, ſeed, or root, ſhould be ſown, ſet, or put into the earth, with the greateſt chance of ſucceſs, will be more fully noticed, ſeen, and pointed out, in ſpeaking of the cultivation and growth of the different ſorts of crops.

The laſt mentioned ingenious writer has likewiſe remarked, that the difficulty of determining the beſt ſeaſon for ſowing, or putting in ſeeds in the ſpring, owing to the variation of the weather in the ſame latitude, as well as of laying down or fixing the exact ſeaſons for ſowing in different latitudes, occaſioned Linnæus to form or conſtruct what he terms a calendar of Flora, which was afterwards adapted to this climate by Stillingfleet; and which conſiſted in obſerving the firſt appearance of the root-ſcions, or flowers of the uncultivated native vegetables; with directions to ſow the *cerealia*, or harveſt-ſeed, when ſuch plants or flowers became viſible. By attention to obſervations of this kind, on ſuch ſorts of uncultivated plants, in many climates, the above writer conceives ſuch tables might be conſtructed, as would point out the moſt proper times of ſowing the moſt uſeful ſeeds or grains in every latitude and ſituation. And he further adds, that another tabular view of the climates where plants grow naturally, and of their native ſituations, in reſpect to moiſture or dryneſs, hill or valley, with the kind of ſoil where they were originally found, might alſo contribute to their ſucceſsful cultivation.

The following is the order of leafing of a few trees and ſhrubs, which Mr. Stillingfleet has put down, as noticed by himſelf, in the county of Norfolk, in the year 1755.

Plants.	Seaſons.	
1. Honeyſuckle	January	15
2. Gooſeberry	March	11
3. Currant		11
4. Elder		11
5. Birch	April	1
6. Weeping willow		1
7. Raſpberry		3
8. Bramble		3
9. Briar		4
10. Plum		6
11. Apricot		6
12. Peach		6
13. Filbert		7
14. Sallow		7
15. Alder		7
16. Sycamore		9
17. Elm		10
18. Quince		10
19. Marſh elder		10
20. Wych elm		12
21. Quicken-tree		13
22. Hornbeam		13
23. Apple-tree		14
24. Abele		16
25. Cheſnut		16
26. Willow		17
27. Oak		18
28. Lime		18
29. Maple		19
30. Walnut		21
31. Plane		21
32. Black poplar		21
33. Beech		21
34. Acacia robinia		21
35. Aſh		22
36. Caroline poplar		22

Alſo, the conformity between vegetation and the arrival of certain birds of paſſage is, he ſays, extraordinary. Of this he gives an inſtance, marked down by himſelf, in the above-mentioned county, in his diary of the ſame year.

April 16th, young figs appear.
17th, the cuckoo ſings.

And he notices, that the word κοκκυξ ſignifies a cuckoo, and likewiſe a young fig; and that the reaſon for it is, that in Greece they appeared together. He alſo ſtates, that the ſame year he firſt found the cuckoo-flower to blow the 19th of April. He likewiſe further adds, that, according to Linnæus, the wood anemone blows from the arrival of the ſwallow. In his diary for the year 1755, he finds the ſwallow appeared April the 6th, and the wood anemone was in blow the 10th of the ſame month. He adds alſo, that the marſh-marigold blows when the cuckoo ſings; and according to his diary, the marſh-marigold was in blow April the 7th, and the ſame day the cuckoo ſung.

It has alſo been remarked, that a due temperature of the ſeaſon, with reſpect to heat or cold, drought or wet, (for all theſe greatly influence the ſtate of the earth,) is eſſentially neceſſary, and ſhould be carefully attended to by the cultivator, when he ſows; but the preciſe time moſt proper for this work cannot, by any means, be invariably fixed, becauſe it will always depend on the concurrence of a variety of circumſtances. The ſeaſons are more or leſs forward, and the ground is more or leſs dry, in ſome years than in others. A proper ſeries of well-made obſervations would furniſh the beſt rules in this reſpect, but certainly would not fix the time of ſowing to any particular day or week, for years to come. Linnæus's method, of carefully obſerving the foliation of trees, &c. would determine the proper time for ſpring ſowing. And Pliny, after mentioning the ſeveral conſtellations by which farmers were guided in his time, inſtructs the farmer with regard to autumnal ſowing, upon a principle ſimilar to that of the great modern naturaliſt. Why, ſays he, does the huſbandman look up to the ſtars, of which he is ignorant, whilſt every hedge and tree point out the ſeaſon by the fall of their leaves? This circumſtance will indicate the temperature of the air in every climate, and ſhew whether the ſeaſon be early or late. This conſtitutes an univerſal rule for the whole world; becauſe trees ſhed their leaves in every country, according to the difference of the ſeaſons. This gives a general ſignal for ſowing; nature declaring that ſhe has then covered the earth againſt the inclemency of the winter, and enriched it with this manure.

It can, therefore, only be obſerved in general, that it is better, as has been ſuggeſted, to ſow early in autumn than too late, provided the ſeaſon will admit of it; becauſe the plants are better able to reſiſt the ſeverity of the winter, after they have acquired a certain degree of ſtrength; and their roots being then longer, and conſequently better fixed in the earth, they will be leſs liable to be thrown out by the froſt. For this reaſon, in particular, perhaps the colder the climate is, the earlier the wheat ſhould be ſown. Some lands are of ſuch a nature, that they ſwell greatly in hard froſts; and ſubſiding again upon a thaw, leave the roots of plants quite bare upon their ſurface. There have indeed been years, in which fields ſown very late, for inſtance in December, have done extremely well; but that ought not, on any account, to be made a rule, experience ſhewing that ſuch late ſowings very ſeldom anſwer. On the other hand, the corn is likewiſe expoſed to many dangers, when ſown too early; for the ſtalks, which ſhoot up before winter, cannot well bear hard froſt; though wheat would not be hurt by them, when only in the blade. M. de Chateauvieux is clearly of opinion, that though the proper time of the year for ſowing be come, the corn ſhould not be put into the ground, if the temperature of the ſeaſon be not favourable; and that, on the contrary, the ſowing of it ought to be deferred, in hopes of a change. If, ſays he, the weather is very hot, and the earth extremely dry, it will be abſolutely neceſſary to wait till ſome rain has fallen; for otherwiſe the ſeed will riſe but very imperfectly. This he is ſure of, by which he contradicts the common ſaying of ſome farmers, that the earth is the beſt granary to keep the corn in. Full of this notion, whenever the ſtated times come round, they ſow, without diſtinction, in wet land or in dry. Even heat does not hinder them: they think their ſeed will certainly ſprout well after the firſt rain; but he has always experienced that the plants have come up thin. But to ſatisfy himſelf ſtill farther on this point, he tried an experiment purpoſely to know whether corn can be ſown, with any reaſonable expectation of ſucceſs, when the weather is very hot, and the earth very dry. Upon reading M. Duhamel's Treatiſe on the Preſervation of Corn, he has obſerved that he had found, by his experiments, that wheat dried in a ſtove, heated to 60 degrees of M. de Reaumur's thermometer, had loſt its faculty of growing. From thence he conjectured, that wheat which ſhould undergo a heat, for example, of 30 degrees during a longer time, would be equally parched up, and rendered incapable of vegetating. He conſidered the earth, when hot and dry, as a kind of ſtove, in which the ſeed, if it remain too long without receiving any moiſture, may become ſo dry, that the greateſt part of it will never be able to ſprout. This reaſoning is juſt, and he therefore determined to have recourſe to that truſty guide, experience.

He was ſure that the wheat which he ſowed was perfectly ſound, and in every reſpect capable of growing. It was, therefore, quite clear, that ſo great a number of grains out of the whole, which did not ſprout at all, loſt the faculty of growing, by their being parched up by the heat and dryneſs of the earth. To be ſtill more certain of this, three weeks after he had ſowed theſe grains, he watered half of them ſeveral times, but to no purpoſe; not one of them roſe, and he found ſeveral of them quite whole in the earth where he had ſown them.

Upon the whole he concludes, from his own repeated practice, that the beſt time for ſowing, in ſuch a climate as Geneva, (which differs very little from our's,) is from the 20th of Auguſt to the end of September; and thinks that even the firſt fortnight in October may be taken in, if the land cannot poſſibly be ſowed ſooner. But he allows of this only in a caſe of neceſſity, and judges that, rather than ſow later, it is beſt to ſtay till ſpring. Thus, ſays he, it is that experience and obſervation teach us to leave off bad cuſtoms, or ſuch as are not founded on principles with which a man of ſenſe may reſt ſatisfied.

In the northern tracts of the iſland, where the ſummer ſeaſon is not of much length, but ſtormy and extremely variable in the ſtate of the weather, early ſowing is ſaid to have been lately found to be attended with many advantages; and that the prejudices in favour of a late performance of this ſort of buſineſs is faſt wearing off; as the good effects of putting ſeed into the ground as early as the ſeaſon will admit, are ſo evident, in ſuch a climate, and the benefit of the practice ſo great and manifeſt, that the moſt prejudiced are beginning to ſuſpect their late ſowings to be bad, and that the practice of thoſe who eagerly catch and embrace the very firſt opportunities which the ſtate of the weather will allow, of ſowing their grain crops, bids the faireſt for ſaving them, at the latter end of the ſeaſon. The hazard to be dreaded from it with ſome ſorts of grain, as oats, is very little, while the benefit to be derived is very great. The advantages of it are very important, in having the beſt part of the ſummer ſeaſon for bringing the crops to full perfection, which increaſes the value of the grain, and in having long days and a favourable ſeaſon for cutting, collecting, and ſecuring the produce in perfect condition: while late ſowing, on the contrary, occaſions the riſk of having the crops expoſed, after being cut, for weeks together, in the fields, under rotting rains, until the ſheaves become each a maſs of vegetation. Inſtead of fixing upon any exact period for commencing the buſineſs of ſowing, which is extremely abſurd, eſpecially in ſuch a climate, the prudent cultivator will regulate his conduct in this reſpect by the ſtate of the weather, and the appearances which have been ſuggeſted above. And as the gardener forms an annual calendar of the weather for himſelf, by what he ſees coming on in his garden; ſo ſhould the farmer, by the courſe of experience and information, learn to diſtinguiſh the proper times for performing the particular operations of his art; not, however, by having recourſe to any preciſe or ſet period of the ſeaſon, but by reference to certain natural appearances, which may indicate the mildneſs or clemency of particular ſeaſons, or the contrary. This may be particularly uſeful in the buſineſs of ſowing different kinds of crops.

In many diſtricts towards the ſouthern extremity of the kingdom, the utility and benefits of early ſowing have been likewiſe noticed and experienced, as the earlieſt ſown crops, eſpecially of the wheat kind, have been almoſt invariably found the beſt. This opinion, which is of ſome ſtanding, is, in ſome meaſure, confirmed by the aſſurance, that nearly the whole of the famous crops which have been produced and talked of by the farmers in theſe diſtricts, were raiſed from early ſowings. Now and then a crop may contradict this concluſion, but they are very rare, and moſtly ariſe from ſome unobſerved circumſtance in the land which produced them. There can, therefore, be no reaſon for doubting that more early ſowing than is at preſent practiſed, in many caſes and circumſtances of land, may be highly advantageous and beneficial to the farmer, not only in the quantity of produce, but in ſeveral other ways.

It is of the greateſt conſequence to the farmer, that ſeed in ſowing be placed in the earth at a proper depth, and in the beſt manner; but experience is yet wanting to determine with due exactneſs, what is the depth which beſt ſuits each kind of grain in different ſoils. In the ſpring ſowings, when there is moſtly much moiſture in the ſoil, from the wetneſs of the previous ſeaſons, leſs depth may be required than in the ſummer, where the land is rendered more dry and parched. From half an inch to an inch and a half, may be fully ſufficient for the ſeeds of the grain, turnip, and carrot kinds, ſo as that they may be fully protected from birds and inſects. And for root-ſets, ſuch as potatoes, from two to four inches, in proportion to the ſtate of the ſoil, may be quite ſufficient.

But, in the very early autumnal ſowings, as from the exceſſive drying heats of the ſummer ſeaſon, there muſt in common be a deficiency of moiſture in the earth, it may be better to have the ſeed put in ſomewhat deeper, as from two inches to three or more, in order that their vegetation may not only proceed more ſpeedily, but their roots be more fully guarded from the effects of the froſty nights, which uſually take place ſoon after ſuch ſowings. And in this way they are more effectually protected from the attacks of birds and other vermin, which are generally more eager and deſtructive in their attacks, from the diminiſhed quantity of food at ſuch periods of the year.

However, in general, as the proceſs of ſprouting or early vegetating is found to be greatly promoted by the ſeed being fully ſupplied with oxygen air, it may be the moſt beneficial practice to have them put into the ſoil, in rather a ſuperficial manner, or but lightly covered, as by ſuch means they may be the moſt fully ſupplied with atmoſpherical air. And for this reaſon, too, it may be the moſt advantageous method to have the ſeeds or roots depoſited in the ſoil as ſoon as poſſible after it has been turned up by the plough or ſpade, as, in ſuch circumſtances, it muſt contain the largeſt proportion of atmoſpherical air among its conſtituent particles; which, it is obſerved by Dr. Darwin, may be neceſſary to ſtimulate into elevation the plume of the embryo plant, as the moiſture of the earth is neceſſary to ſtimulate the root into its elongation downwards.

The particular ſtate of the ſeaſon and climate in which the ſowings or plantings are performed, may likewiſe have ſome influence on the crops. It has been commonly ſuppoſed that the beſt practice is that of ſowing in dry ſeaſons, and ſetting out plants in ſuch as are moiſt; but it is obvious, a late a late writer thinks, that, in ſo far as the ſowing is concerned, this buſineſs ought, in ſome reſpect, to be conducted according to the differences of the qualities of the lands and the nature of the climate, in regard to its warmth, or the contrary. Thus, in the drier and more mellow and porous deſcriptions of ſoils, and the more warm and genial climates, it may, in many caſes, be advantageous, not only to ſow in the wet, or rather moiſt ſeaſons, but alſo at more early periods, than in ſuch as are more retentive of humidity; as from the moiſture being commonly, in ſuch ſorts of lands, quickly diſſipated, a more certain and expeditious vegetation of the ſeed may in this way be ſecured. But in the more heavy and wet kinds of ſoil, where the climate is colder, it will conſtantly be a more beneficial method to chooſe, if poſſible, a dry and warm ſeaſon for performing the buſineſs of ſowing or putting in the crops, as by ſuch means the grain will be more certain of vegetating, and in leſs danger of periſhing by the over-abundant wetneſs, and the want of heat in ſuch lands and climates. And it has been juſtly remarked by Dr. Darwin, that in ſome clayey grounds, much ſoftened by rain, if the ſeed be put into holes and a dry ſeaſon ſucceed, an almoſt impenetrable cruſt may be produced by the quick exhalation of the moiſture, and what is termed by the farmers, the ſetting of the clay; and in this manner the vegetation and early growth of the crop be much retarded, or in a great meaſure prevented. And that though it has been ingeniouſly ſuggeſted that uſeful purpoſes in the early vegetation of ſome ſorts of plants may be anſwered by the ſowing of the fruits or huſks that ſurround particular kinds of ſeeds and berries, no experiments have yet been made to ſhew whether the ſowing the chaff, or covering of the grain with it, might not, in particular circumſtances of the ſoil and climate, be of utility in affording it warmth and protection in the firſt ſtages of its growth.

With regard to the methods of ſowing or putting the ſeed into the earth, there are different ones in uſe, not only in diſtricts where the nature and qualities of the ſoils are different, but in thoſe in which they have have much ſimilarity. It is obſerved, that the moſt general and common mode, as well as that which is more or leſs prevalent in almoſt every part of the kingdom, is that of ſowing or caſting the ſeed over the ſurface of the ground by means of the hand, having it afterwards covered to a proper depth by harrowing. In this method of performing the buſineſs, the moſt uſual practice, eſpecially where the ridges are equal in breadth, and not of too great a width, as five or ſix yards, is that of diſperſing the ſeed regularly over each land or ridge in once walking round; the ſeedſman, by different caſts of the hand, ſowing one half going and the other in returning. In doing this, it is the cuſtom of ſome ſeedſmen to fill the hand from the baſket or hopper which they carry along with them, as they make one ſtep forward, and diſperſe the ſeed in the time of performing the next; while others ſcatter the ſeed, or make their *caſts*, as they are termed by farmers, in advancing each ſtep. Mr. Parkinſon ſtates, in the account which he has given of Iriſh farming, that he found a good ſower the moſt difficult thing to be met with; in fact, he did not himſelf know the true art of ſowing ſeed broad-caſt until he went to America, and the man from whom he took the idea there attracted his notice, from the particular manner in which he walked while ſowing, which was preciſely as if he had been blind, keeping his eyes on the ſeed as he threw it, by continually looking upwards. It is conſequently evident, that in accompliſhing this buſineſs with regularity and exactneſs, upon which much of the ſucceſs of the crop muſt depend, there is conſiderable difficulty, and the proper knowledge and habit of which can only be acquired by experience. Wherever this method of putting in the ſeed is had recourſe to, it is conſequently of importance for the farmer either to perform the operation himſelf, or to be careful in ſelecting ſuch perſons as are converſant with the buſineſs, as he may otherwiſe incur much unneceſſary expence in the waſte of ſeed, and run conſiderable riſk in reſpect to his crop. Mr. Marſhall, finding a great waſte and inconvenience attending the broad-caſt ſowing, ordered his ſeedſman to walk on the left-hand inner furrow, with his face towards the land to be ſown, and to make his caſt diagonally, not acroſs the land. This gave him a great ſcope; and after a few minutes practice he made very good work: before night he walked at the rate of three or four miles an hour, and though a young ſeedſman, made as good work as could be wiſhed. A man walking in the ſmooth, open, inner furrow, may ſow three acres in leſs time, with more eaſe, than one walking among the rough clods and looſe mould could ſow two acres. This method proved ſuperior to the uſual way, being cropped as well, and with leſs ſeed. The extra expence of ſowing is about two-pence an acre, but the ſaving of the ſeed was at leaſt two ſhillings *per acre*. The method obſerved was for the ſeedſman to walk up one ſide of the ridge or bed, and down the other ſide; always keeping his face, and the hand with which he ſows, towards the bed he is ſowing. He always keeps his eye on the edge of the oppoſite interfurrow, and delivers his ſeed principally on the ſide of the bed next to it: as he returns, the ſides of courſe are reverſed, and the beds become evenly ſeeded. An old ſeedſman, who has been uſed to throw large handfuls with all his might, in wide caſts ſtraight acroſs his walk, will find it aukward at firſt to make the ſnug diagonal caſt which is neceſſary in ſowing five-bout beds ſingly.

But it is obſerved, that the uſual way of ſowing in broad-caſt cannot anſwer all the intentions of placing the ſeed properly in the earth, and muſt be attended with ſeveral inconveniencies: ſuch as the ſeed's becoming the prey of various birds and animals; its being laid ſo ſuperficially, that the ſun often parches it, or a long continued rain, inſtead of promoting a kindly vegetation, ſoaks into the grains, and burſts them; the ſeed is very unequally ſown, becauſe of the inequality of the handfuls which different ſowers graſp, and a great part of it neceſſarily falls together into hollows, where the ſurface of the ground is any way unequal, &c. And that, ſenſible of theſe diſadvantages, farmers have, eſpecially for their winter grain, ſometimes adopted the method of ſowing under-furrow, that is, ſowing one half of the ſeed in broad-caſt, and then ploughing it in; and afterwards ſowing the other half, which is covered by harrowing. But this method is alſo liable to almoſt as many objections as the other; for the quantity ſown in each particular ſpot, and the equal diſtribution which ought to take place throughout the whole, cannot but be even more uncertain than in the broad-caſt, where the whole is ſown at once; nor dares the farmer, in this ſowing under furrow, omit ſowing the ſecond quantity, leſt a great part of what has been ploughed down be buried ſo deep that it cannot riſe, eſpecially if the ſoil is at all ſtrong. And another general fault in the common way of ſowing is, that too much ſeed is employed; partly becauſe cuſtom has eſtabliſhed a kind of rule in that reſpect, and partly on account of the allowances which it is neceſſary to make for what the birds eat, and for what lies too deep ever to riſe; the circumſtances by which a very great quantity of corn is abſolutely loſt. See BROAD-CAST *Sowing*.

There are inconveniencies and difficulties in this manner of ſowing, on many other accounts; as where the lands or ridges are liable to vary in their dimenſions or breadths at the different ends or parts, the ſowing is not performed without great trouble and waſte of ſeed, as the ſcattering of it, in turning ſo often on the different parts, is prevented from being effected in ſo regular and exact a manner, as when the ſeedſman is directed by a particular furrow-ſlice. The ſowing is, therefore, ſometimes very imperfect in ſuch caſes, even with good ſeedſmen. In ſowing in this way there are probably, too, leſs economy, leſs exactneſs in many points, and leſs attention provided for the management of the crops, while they are growing afterwards.

Sowing in the broad-caſt manner has, however, many advocates, and is probably the moſt prevailing practice in moſt diſtricts of the kingdom; and ſome think that, in common, all ſorts of grain produce the largeſt quantity on the acre, when ſown in this method. It ſhould, notwithſtanding, perhaps give way to the machine practice of ſowing, wherever it can be had recourſe to with eaſe and facility.

In general it is, however, ſuppoſed, that theſe inconveniencies may be prevented by the drill method of ſowing, which drops the ſeed at whatever depth and diſtance experience has ſhewn to be the fitteſt for the particular kind which is ſown; fills all the furrows with earth, ſo that none of the grain remains uncovered; and lets fall into each furrow the exact quantity of ſeed which has been found to be moſt proper. In this way the ſeed is of courſe diſtributed with greater regularity and exactneſs, both in regard to depth and the diſtance of the rows, by which the crops not only ſucceed better, but are more capable of being aſſiſted in their culture afterwards; while much ſeed is ſaved. It is likewiſe believed to have many other advantages over the common method of ſowing. See Drilling.

It evidently admits more air and light for the growth and maturation of the crops, and produces a better and more abundant quantity of them. In ſowing wheat and other grain crops in this way, they ſhould probably not have more ſpace between the rows than about ſeven inches; but in other kinds it ſhould vary, according to the nature and habits of the growth of the plants, and the ſtate of the ſoil. The ſowing in this way in too thin a manner has often been injurious to the cultivator.

Sowing is ſometimes performed likewiſe in methods between thoſe of the broad-caſt and the drill, as by means of tools with different numbers of ſhares. The ſowing is, in theſe caſes, executed, when the land becomes firm and rather ſolid, immediately after the tool, over the whole ſurface of the land in the broad-caſt way, the ſeed moſtly falling into the little furrows or openings that are left by the implement. In ſowing in this manner, there are the advantages, it is obſerved, of having the land firm between the ſmall drills, of the ſeed taking firmer hold of the ground, of its being readily performed and attended with little trouble, of the ſeed coming up with great regularity, of the crop being leſs liable to accidents, in conſequence of the action of the ſun and air being more free, of its affording a greater facility in the after-culture, and of the quantity of grain being increaſed. On light and dry ſoils, this mode of ſowing is ſaid to be attended with the beſt effects. Some, however, think that one caſt before and another after this tool is the moſt preferable mode of ſowing.

But whatever may be the benefits of ſowing in the drill manner, it has hitherto made no very great progreſs, though it is evidently a moſt uſeful method.

There are alſo other methods of ſowing, as by dibbling, dropping, and ſetting with the hand, which, under different circumſtances, are found very beneficial modes. See Dibbling and Ridge.

Theſe are, however, methods which are only ſuited to particular ſituations and circumſtances of land.

All theſe different ways of ſowing, or putting the ſeed into the ground, may perhaps be found uſeful, and be practiſed with ſucceſs, under different circumſtances and conditions of land; as where one mode is improper, or not capable of being had recourſe to, another may be ſubſtituted, in order to ſupply its place, and accompliſh this important buſineſs of the farmer, in the moſt proper and deſirable manner.

In ſowing ſmall ſeeds for plants, conſtant attention is neceſſary to the times or periods at which the plants will be wanted for ſetting out as crops, and the different ſowings made accordingly. For theſe ſowings, ſmall ſuitable portions of land, in a fine ſtate of preparation and cultivation, and which are well ſecured, are always to be choſen. The ſowings for cabbage, and other ſimilar ſorts of plants, ſhould be made at two or three different times, both for the autumn and ſpring crops, in order that the plants may be ſtrong and healthy. And for raiſing ſpring plants of the ſeveral different other kinds, as thoſe of the lettuce, or other ſimilar ſorts, the ſeeds ſhould be ſown at two or more ſeparate times, in the early ſpring ſeaſon, that good plants may be in readineſs for ſetting out, when wanted. In general, ſmall ſpaces of ground will be ſufficient for theſe purpoſes, as they may contain the quantities of plants which are neceſſary. The ſowings, in ſuch caſes, are to be made in a regular, but not too thick a manner; the plants being afterwards, when of ſome growth, properly thinned, that they may become ſtrong plants. In ſowing ſome ſorts of ſmall ſeeds, it is uſeful to mix a little aſhes, or ſome other ſimilar ſubſtance, with them, to make them ſow better. The ſowing of graſs-ſeeds ſhould always be performed in as regular and exact a manner as poſſible. See Grass and Grass-*Land.*

Sowing *of Seeds*, in *Gardening*, the practice of putting ſeed into the ground, in the garden manner; in which different methods are made uſe of, according to the ſorts: as broad-caſt ſowing and raking-in, drill ſowing, bedding-in ſowing, &c.; in each of which there are ſome advantages in different ways.

The firſt is the moſt common and expeditious method of ſowing, both for many of the principal crops to remain, and for tranſplantation; and is performed by ſowing the ſeed with a ſpreading caſt evenly all over the ſurface of the ground, either in one continued plat, or when divided into beds, which is immediately raked with a large rake, to bury all the ſeeds a due depth in the earth; ſome requiring to be raked in as light as poſſible, others half an inch or an inch or more deep, according to their kinds and ſizes, &c.

In preparing for this method of ſowing, the ground is previouſly dug over in the common way, or in ſuch a manner as is neceſſary; making the ſurface level with the ſpade, as the work proceeds; and, according to the nature of the ſeed, ſowing it as ſoon as poſſible afterwards. And this ſort of ſowing ſhould generally be performed in dry weather, particularly the early ſowings in winter and ſpring; but in hot weather, in ſummer and autumn, it may often be eligible to take advantage of ſowing immediately after a ſhower of moderate rain. And as to the ſowing the ſeed in the broad-caſt way, it is effected occaſionally both with an open and locked hand. In the former caſe, it is performed by delivering the ſeeds with an open hand, and broad-ſpreading caſt, as practiſed in ſowing corn in the open fields, previouſly ſtepping out the ground in breaks, or certain widths, tages of theſe methods, ſee the articles DRILL, DRILLING, HOEING, HUSBANDRY, and *Drill* MACHINE.

Mr. J. Horn of Dover, Kent, conſtructed an *univerſal five-furrow machine* of this nature, which he recommended as ſuited for either broad-caſting or drilling all the different ſorts of grain, pulſe, and ſeeds, with equal regularity and eaſe, as well as in any quantity or proportion, and depth, that may be thought proper. And which alſo poſſeſſes, he ſays, the peculiar advantage of ſowing turnips, ſo as to enſure the crop againſt the ravages of the fly. This advantage is obtained by ſowing the *uſual quantity* of turnip ſeed *broad-caſt* by the machine, and at the ſame time ſtriking furrows at a proper diſtance apart in the land; by this means part of the ſeed is depoſited in the drills, and the reſt ſown in broad-caſt between them, ſo that if it proves a dry ſeaſon, it is favourable for that depoſited in the drills, if a wet ſeaſon, for that which is ſown broad-caſt between them: and if that part of the ſeed which is ſown broad-caſt is carried away by the fly, that which is depoſited in the drills, by coming at another period of time, is ſaved, and *vice verſâ*. If the whole grows, the farmer has then the opportunity of ſelecting the moſt vigorous plants from both. But notwithſtanding theſe ſtated advantages, the machine is, we believe, little employed by the cultivators of land.

No machine, as far as we know, has hitherto been invented, which is well contrived for, and adapted to, the purpoſe of general ſowing, though a great number of attempts of this kind have been made at different times, in the view of ſupplying ſo great a defect in the agricultural machinery of the country. They have all been found on trial, and when put fully to the teſt, to be materially defective in ſome important point or other, which rendered them either wholly uſeleſs, or only capable of being employed under particular circumſtances. This has been equally the caſe, whatever may have been the nature or kind of conſtruction, in which they have been formed. In order to conſtruct a machine to be generally uſeful in this intention, it muſt be free from every kind of fault or defect in the delivery of all ſorts of grain, pulſe, and ſeeds, be capable of very great nicety and variation in ſowing all theſe different articles, be very eaſy and exact in the movements of the internal parts, have great latitude of motion, giving way, and taking up in the ſhares or other parts, which are made uſe of in forming the little furrows or drills in the land, be capable of being guided and directed with eaſe and facility in a regular, ſteady, and exact manner, be cheap and reaſonable in the expence of its conſtruction, &c. But very few of theſe materially important points and objects have yet been accompliſhed in a full, complete, and ſatisfactory manner, in any of the ſowing machines which have been contrived and conſtructed. Some of them, as already ſuggeſted, have a defect in ſome one of the particulars, ſome others in another, by which means they become neglected and of no uſe to the farmer, whoſe ſowing muſt at leaſt be performed with a certain degree of correctneſs.

It is evident, therefore, from what has been ſaid, that the conſtructors of ſuch ſorts of machinery, to render it generally uſeful, ſhould have a full and competent knowledge of the moſt proper proportions or quantities of the above ſeveral kinds of articles which are to be ſown, as well as of the moſt ſuitable widths, diſtances, or ſpaces between the rows, which are neceſſary to be ſown and left, in different caſes and circumſtances, in ſowing with machines of this nature, as where this is not the caſe, there muſt frequently, if not generally, be much loſs ſuſtained in making ſuch machines to ſow too much or too little ſeed, as the differences in the ſeed, and the ſpaces which are required in different ſtates and circumſtances, and conditions of land and ſeaſon, are very great. The proportions of ſeed that are the moſt beneficial for early and late ſowing are by no means the ſame; nor does different kinds and ſtates of the ſoil admit of the ſame. They may differ alſo on ſome other accounts. The ſpaces, which are the moſt uſeful, likewiſe vary greatly in different kinds of ſoil, crops, and cultivation. It is conſequently ſeen, that a perfect knowledge of this ſort is abſolutely neceſſary, and that ſuch ſowing machines as are incapable of ſowing any kind of grain or ſeed in any proportion or quantity which may be required, are by no means fit for public or general uſe. In the internal parts of machines of this ſort there ſhould be great ſimplicity and incapability of being put out of order, the moving cylinders, or other parts ſupplying their places, being made ſo as to admit of great variation in the degrees of their motion or velocity. The utility of tin cylinders for this purpoſe is ſomewhat doubtful, and the ſhaking or ſifting principle has not been found to ſucceed well, except in the caſe of round ſeeds, ſuch for inſtance as thoſe of the turnip, cabbage, rape, clover, and ſome other ſimilar kinds, and even in theſe caſes ſometimes, with ſome of theſe ſeeds, a ſeed will ſtick in a hole which will permit another ſort to paſs in a free manner, and in thoſe ſorts which moſt readily paſs, there is rarely a deficiency of ſome ſmall ſeeds, of which two are capable of entering the ſame hole at the ſame time, which, by ſticking faſt together, impede and prevent the delivery in ſuch machines. On this account, ſome ſowing machines ſow too much of one ſort of ſuch ſeeds and ſcarcely half enough of another. Pierced cylinders of the tin kind might probably be made to ſow peas, which are nearly round in their form; but they would not be found to anſwer the ſame purpoſe for wheat or beans, and ſtill leſs for barley or oats. And the ſame may perhaps be the caſe in ſowing ſome other ſorts. It is therefore probable, that wooden or metal cylinders, which have grooves on their ſurfaces, and bruſhes to promote and regulate the delivery, are the beſt modes which have yet been diſcovered for effecting the purpoſe of ſowing in a proper manner in theſe machines, though they are far from approaching any ſort of perfection in the buſineſs.

The ſhares, or other contrivances, which are made for the purpoſe of forming the little drills or furrows in the ground for the reception of the ſeed, ſhould have great power and facility of moving and giving way in an upward direction in caſe of their meeting with any hard impeding ſubſtances in the ſoil, and that they may be uſed on all ſorts and forms of ridges. They ſhould alſo have the capability of being wholly taken up, when occaſion may require, as in turning at the ends of the ridges, and in removing from one place or field to another, in order to prevent the machine from being broken and deſtroyed.

Theſe machines ſhould likewiſe have great eaſe and capability given them of being directed and guided, while in their work, by the exact regulation of the ſhare or ſowing parts only, or by theſe in connection with the other parts, as where there is a want or any material incorrectneſs in this reſpect, the after-culture of the crops may be greatly impeded or wholly hindered from taking place.

There is, conſequently, a variety of points and circumſtances which ſhould engage the attention and conſideration of the agricultural artificer and mechanic, who is anxious to ſucceed in the conſtruction of uſeful machinery of this ſort, and particularly that of a general or univerſal ſowing-machine.

The article *Drill* MACHINE contains an account of ſowing

ing-machines that are intended to ſow the ſeeds in drills, and a minute deſcription of one invented by Mr. Salmon, which is very ſuperior to the others, as it is capable of being guided, and thus laying the drills in exact ſtraight lines, a circumſtance of the firſt importance in the operation of drilling, that the horſe-hoe, which is to paſs in the ſpaces between the drills, may not cut the young plants.

The term *ſowing-machine* is almoſt excluſively confined to ſome implements lately introduced for ſowing ſeeds in the broad-caſt manner, that is, for diſtributing them equally over the whole ſurface; and this operation can be much better performed by the aid of a machine, than by ſcattering it abroad by hand, as in the ordinary method. The moſt approved ſowing-machine is that of Mr. Bennet's, which is extremely ſimple: a ſlight wooden box, or trough, of a triangular figure, about five inches each ſide, and five or ſix feet in length, is held horizontally by the ſower, who carries it ſuſpended by a belt round his neck, ſo that the length of the trough is before his breaſt croſswiſe. The trough is filled with the ſeed which is to be ſown or diſtributed; and at the bottom angle of the trough is a ſlight wooden axle, extending the whole length of it. This axle is turned round by an endleſs band and a wheel, which is mounted in a frame upon the top of the trough, and furniſhed with a ſmall handle, conveniently ſituated for the ſower to turn it round, and thus give motion to it. The axle has ſeveral notches, or ſmall cups, cut in it at various places, and the bottom angle of the trough is open all the length; but the axle lying immediately beneath, cloſes the opening, and by hair-bruſhes is made ſo cloſe, that no ſeed can paſs, except when the axle is cauſed to revolve; the cups or notches then become filled with the ſeed, which is contained in the bottom of the trough, and they carry down their contents of ſeed through the bottom of the box, and it drops on the ground in a ſlight ſhower before the ſower. The cups or notches are ſo arranged at intervals round the axle, that they will diſtribute the ſeed in the moſt equal manner poſſible, upon the whole breadth of ground over which the trough moves, when it is carried forwards as the ſower walks in a ſtraight line from one ſide of the field to the other; but the regular diſtribution of the ſeed, in the direction lengthwiſe of his walk, will altogether depend upon the preciſion with which he turns the handle of the wheel with a regular motion. As this is rather difficult to effect, Mr. Bennet has made another machine, which runs upon a wheel, like a wheel-barrow; and the motion of this wheel is communicated by wheel-work to the central axle, ſo that it turns regularly, and diſtributes the ſeed always in a given proportion to the diſtance of land over which it travels. The trough of this latter machine is the ſame as the former; and the axle, with the notches, is ſituated at the bottom of it; but, inſtead of the belt, the trough is carried, by being fixed tranſverſely acroſs two long rails, which, at the fore-end, have the wheel between them, and the other ends are formed into handles, by which the ſower ſupports the machine, and wheels it before him in the ſame manner as a wheel-barrow. A pinion is fixed on the axle of the wheel cloſe to the ſide of it, and turns a wheel and ſpindle, extending to the wheel on the axis of the trough, to keep the ſame in conſtant motion, and deliver the ſeed regularly upon the ground, in proportion as the machine advances; and means are provided by which the rate at which the axle delivers the ſeed can be increaſed or diminiſhed at pleaſure, to diſtribute more or leſs ſeed upon the ground.

Another claſs of ſowing-machines are called dibblers, and are intended to make a ſmall round hole to receive the ſeeds, and then to drop them into it. We have ſeen ſeveral attempts to perform this operation by machines, but they have not fully ſucceeded. One of them was by means of a wheel provided with points projecting from its circumference, and placed at ſuch diſtances from each other as the holes were intended to be. The machine being wheeled along in the ſame manner as a wheel-barrow, the points of the wheel were intended to dibble or pierce holes in the ground over which it paſſed, and the machinery in the ſeed-box, which was fixed upon the handles behind the wheel, followed, and let fall the intended quantity of ſeed into each hole ſo made. The objection to this machine was, that the points of the wheel, in lifting up or drawing out of the ground, drew up with them lumps of earth, and ſoon clogged the whole.

An ingenious dibble or ſowing-machine, for acorns, was preſented to the Society of Arts by Mr. Waiſtell in 1811, an account of which is publiſhed in their Tranſactions for that year. The dibble, or piercer, which makes the hole in the earth, is an iron rod, a quarter of an inch in diameter, and about four feet in length, round pointed at the lower end, that it may penetrate the ground. At the upper end of the rod a handle is fixed, to draw it up and force it down by. This rod is contained within the hollow of a wooden tube or ſtaff, of the ſame length as the iron rod, and about two inches in diameter externally, ſo that the iron rod can be drawn up and down therein in the ſame manner as a rammer in the barrel of a muſket: the lower end of the ſtaff terminates in an iron tube, to which the iron rod is cloſely fitted, and the tube is made taper on the outſide. The point of the dibble, when put down into the tube, projects a very ſmall quantity beyond the end of the tube, and the whole is formed to a regular conical point, proper to pierce the ground. On one ſide of the ſtaff a tin tube is united to it, and communicates ſideways with the interior paſſage, or bore of the ſtaff, at about ſix inches from the point. This tube is continued nearly up to the top of the ſtaff, and is withinſide of the ſame bore as the aperture through the ſtaff.

The dibble is forced into the ground, to make the hole, by two handles, which project from it croſsways, on each ſide, at the upper end; and on each ſide of its point, or rather on each ſide of the iron tube which contains the iron rod, and forms the point of the dibble, are fixed two wings, or leaves of iron, projecting on each ſide about three inches. The operation of ſowing with this implement, is to force the dibble into the ground by its handles, and thus make the hole; then draw up the iron rod, ſo that its point riſes above the place where the tin tube communicates with the interior paſſage of the ſtaff, and drop the acorn down the tin tube, and it will paſs through that communication, and drop into the hole; the rod being preſſed in again, carries the acorn down to its place, in the bottom of the hole made by the point of the dibble. In drawing out the dibble from the ground, it muſt be gently turned round backwards and forwards, by which means the wings, or leaves, projecting ſideways from its point, will looſen the ſurrounding earth, and cover up the acorn.

A great advantage propoſed by the inventor of this implement is, that acorns can be planted by it in the middle of any buſh, without firſt removing it. For this purpoſe, the dibble is to be preſſed down into the ground through the buſh; then raiſing up the rod, ſo that its point will be raiſed above the point of communication between the interior of the tin tube and the cavity of the ſtaff, an acorn is to be dropped into the tin tube, which will fall down through the tube into the hole made by the point of the dibble. In drawing up the dibble out of the ground with the motion above-deſcribed, the earth will be covered in upon the acorn. Thorns, buſhes, and thickets, ſays Mr. Waiſtell, are the natural guardians of young oaks from the depredations of cattle of all kinds, in foreſts and other grounds where they paſture; and by this means, acorns may be depoſited in the interior of buſhes, as well as in open grounds, with rapidity and accuracy.

SOWING-*Plough*, that inſtrument of this kind which is employed for the purpoſe of ſowing, or of forming the land in a proper manner for the ſeed being put into it, after it has undergone the neceſſary ploughing. There are many ploughs of this ſort in uſe in different diſtricts of the kingdom, and they are conſtructed in ſeveral different ways in different places, and with very different numbers of ſhares, or contrivances for forming the little drills, or ſmall furrow-openings in the land, which are to receive the ſeed. They are made with three, five, ſeven, and nine of theſe ſhares or parts, according to circumſtances, and the intentions of ſowing which they are to ſerve. Low iron wheels, in combination with tines or teeth, are ſometimes likewiſe made to anſwer the purpoſe of forming the little openings for the ſeed in theſe ploughs. And they have many other variations in their ſtructure in other parts. Theſe kinds of ſowing-ploughs are now beginning to make their way, ſomewhat rapidly, in the mouldering chalky-land diſtricts of the country, particularly where the ſoils are of a light, dry, friable nature. They conſtitute, in ſome meaſure, a plan between the drill and broad-caſt methods of ſowing, as the ſeed is ſown or ſcattered over the land by the hand, after it has been furrowed by the plough in a ſuitable manner. The Berkſhire nine-ſhare ſowing-plough is ſaid to be uſed with the moſt beneficial effects. After the land is properly prepared and rolled, this plough is paſſed over it, and the grain or other ſeed ſown broad-caſt and harrowed in; by which means it comes up, it is obſerved, with as much regularity as if it had been drilled. It is indeed ſuggeſted, that in many ſoils and ſituations this ſowing-plough might undoubtedly be found preferable to the beſt drill-machine. See SOWING.

The preſſing-plough, and probably ſome others, are of this kind, though they may poſſeſs other highly uſeful properties, in different intentions. See *Preſſing*-PLOUGH.

The utility and preference in favour of theſe ſorts of ſowing-ploughs, probably, in a great meaſure, depend upon their being attended with but little labour, trouble, or difficulty in the performance of the buſineſs, and their requiring little knowledge in the perſons who conduct and manage them. There may alſo be ſomething on ſuch light ſoils, in their rendering the land more ſolid, in putting in ſome ſorts of crops, as thoſe of the wheat kind, &c. See TREADING and WHEAT.

SOWING-*Roller*, that ſort of implement of this kind which is conſtructed for the purpoſe of ſowing different ſorts of grain and ſeeds. Implements of this nature have been lately contrived, and formed in ſeveral different modes and manners, in the view of effecting this intention in a more complete and ſatisfactory manner than has been commonly the caſe formerly. They are, however, for the moſt part, ſtill defective in all or ſome of the ways which have been noticed in ſpeaking of ſowing-machines, and to be remedied, moſt probably, in the ways, and by the means, which have been there ſuggeſted and pointed out. See ROLLER.

In a ſowing-roller which has been lately invented, the heavy expence commonly attendant upon conſtructing ſuch implements, and their being moſtly applicable only to one particular purpoſe, has induced the inventor to fix and attach a complete ſeed-diſtributing apparatus to the common field-roller, which is capable of ſeeding, it is ſaid, any given number of little rows or furrows made in the ground by itſelf, or of ſowing the land broad-caſt, if that mode ſhould be preferred. This ſowing implement, which is wholly formed on the above principles, from its very great powers, the eaſe with which it may be conſtructed, being ſuch as that any tolerable good village wheelwright may put together, and the little liability there is of its being out of order, warrant, it is ſuppoſed, the aſſertion, that it is a more effectual ſowing tool than any which has yet been offered to the public. It is in this caſe calculated and conſtructed on a narrow ſcale, that is, with a roller of only four feet two inches in length, and twenty-eight inches in diameter; as ſuch a block of wood is eaſily to be procured in almoſt any ſituation, but it may be formed of much larger dimenſions.

This ſowing-roller conſiſts of a roller-part, the gudgeons of which pierce the ſhafts of the tool, and after paſſing through them about two inches, are bent at right angles, ſo as to form cranks, which, by means of parallel bars of communication, give a rotatory motion to a tin cylinder, which, for the ſowing of ſmall ſeeds, ſuch as thoſe of turnips, rape, cabbage, clover, and others of the ſame nature, may be about a foot in diameter, but for different ſorts of grain larger, and perhaps ſomewhat differently modified. This tin cylinder is to be ſhut at each end, by means of a piece of ſtout board, turned ſo as to fit exactly, and to be faſtened in with very great nicety and firmneſs. The whole ſurface of it is to be pierced with ſmall holes, ſo that when it is furniſhed with ſeeds, the revolutions of it may cauſe them to paſs through into the funnel for their diſtribution. It is alſo internally divided and ſeparated by ſeveral diaphragms of the tin kind, by which the ſeed is prevented, when the implement is on a declivity, from being thrown all to one end of the cylinder, by the force of its own weight or gravity. Each compartment is provided with a ſmall ſlider, which moves in a groove internally, by means of which it is ſupplied with ſeed when it is wanted. The axis, or axle-tree, is ſquare, from the end or place of its entrance into the cylinder, to that of its exit at the oppoſite end. Both ends of this axis, as well as thoſe of the gudgeons in the ends of the roller, are turned for cranks; but in order that there may be no poſſible check given to the motion of the cylinder, the two cranks, that is thoſe of the roller and of the cylinder, on the right ſide of the implement, are to be ſet at right angles with the direction of thoſe on the left ſide of it, ſo that when the former are vertical, the latter will be horizontal; as is ſeen to be the caſe in many pieces and ſorts of machinery, as in thoſe of windlaſſes for pits and wells, hand-mills, and ſome others, where two perſons are employed, one at each end of the power which gives the motion.

There is a ſtrong plank, about two inches in thickneſs, and two feet at leaſt in depth, which reaches all acroſs the tool; the whole of it that is above the ſhafts, reſting upon them by means of a ſhoulder at each end. It is ſupported by a ſtrong iron ſtay, as it is a part which muſt be very firm, on account of the whole ſtreſs of the ſhares bearing upon it. All of it that is above the ſhafts, which need not be more than eight inches, ſerves as a foot-board, while that part which is under the ſhafts forms the front part of the ſeed-funnel. A ſtrong wooden ſlip or ſtrap, for a ſupport, ſhould be faſtened firmly, at its upper end, to the ſide of the ſhaft, taking care that it be out of the way of the crank on the axis of the roller. The other end may be fixed as a buttreſs, at the back of the projecting elbow of the above plank or board, ſo as to ſtrengthen and enable it to reſiſt the preſſure occaſioned by the action of the ſhares. The back part of the funnel is formed by a thin deal board, which is ſecured at its upper part to the ſhafts. The ſides of the funnel are cloſed under the ſhafts with moderately thin deal boarding. The funnel, when ready for directing the ſeed, reaches within four or five inches of the ground; it has no bottom, ſo that when the implement is in motion, it will, in this ſtate, ſow broad-caſt with much regularity and exactneſs. When thus employed, however, inſtead of having the chain which hangs in loops, at ſix inches apart, all along the bottom part of the back-board, for the purpoſe of covering in the ſeed, and filling up the little furrows made by the ſhares in the buſineſs of drill-ſowing, a broad but ſhort harrow is to be fixed to, and appended from, the bottom part of the back-board, which, paſſing before the roller, covers the broad-caſt work, which is immediately afterwards compreſſed by the roller coming over it, and finiſhed. It muſt be noticed, that the loops of the chain uſed in drill-ſowing hang in thoſe parts of the back-board that lie over the intervals between the ſmall furrows. This is managed by having a number of tenters, into which a long chain may be looped, as the occaſion may require. The ſhares have each a ſtandard, the latter being long enough to meaſure the whole depth of the front board or plank noticed above. The foot part of theſe ſpreads a little at the heel, ſo that it may ſtand open to about two inches and a half at that part; the length of the ſole part may be five inches, and the inſtep about three inches, the point and the upper part being ſharp. At the back part of each ſtandard are two ſlit-ſprings, which ſerve to keep them tight, when they are put into the groove in the front board or plank. At the top, in the front part, for about eight inches downwards, the ſtandards are furrowed in an horizontal manner, ſo as to form teeth or cogs, which fit into the grooved bar that paſſes all acroſs the tool, whereby the ſeveral ſtandards, and the ſhares that are fixed to them, are capable of being either raiſed or lowered. This is effected by means of the ſmall winch handle. There are two rows of ſtaples driven through the front board or plank, and rivetted firmly within the funnel. Theſe ſtaples ſhould admit the ſtandards to paſs up them from below, when fitting into their places, and ſhould fit them exactly in breadth; but in depth ſome allowances ſhould be made for the play of the two back ſprings. The upper row of ſtaples ſhould be juſt between the ſhafts, the lower one within four inches of the bottom of the board. Great care ſhould be taken to place thoſe in the upper row perfectly in a line with thoſe below; and both lines ſhould be in a correct parallel with the grooved bar, otherwiſe they never will work up and down ſo freely, or in ſo proper a manner, as they ought to do. The ſtandards ſhould be about half an inch in breadth and nearly an inch in depth, from front to back, excluſive of the ſlit-ſprings, which are not to be rivetted, but welded on, that they may not weaken the ſtandards, which muſt alſo be perfectly ſmooth and ſtraight. The number of the ſtaples in each row is ſeventeen; but as it is ſuppoſed that ſix inches will be as ſmall an interval as will ever be wanted in this method of ſowing by means of drills, no more than nine ſhares can ever be required for the purpoſe.

The tabular form and repreſentation which is introduced below will give a clear view of the manner in which the ſhares ſhould be diſtributed in the ſeventeen ſets of ſtaples, which are calculated for ſowing any number of rows in this implement; conſidering always that the tool, in returning, muſt paſs more or leſs diſtantly from its preceding track, according as the vacancies on the right of the row of ſhares may indicate: thus, for inſtance, when ſowing at a foot interval, as both ends of the line will bear ſhares, a foot diſtance ſhould be allowed, as is exemplified in the third column below.

Sowing-Diſtance Table.

Staples.	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	In returning leave a ſpace of
Intervals of ſix inches.	+		+		+		+		+		+		+		+		+	Six inches.
Nine inches.	+			+			+			+			+			+		Six inches.
Twelve inches.	+				+				+				+				+	Twelve inches.
Fifteen inches.	+					+					+					+		Nine inches.
Eighteen inches.	+						+						+					Three inches.
Twenty-one inches.	+							+							+			Twelve inches.
Twenty-four inches.	+								+								+	Twenty-four inches.

It is to be noticed, that the croſſes in the above table ſhew in which of the ſtaples the ſhares ſhould be ſet, in order to ſow at the diſtances expreſſed in the firſt column of it; all the other ſhares may be drawn up, or wholly taken out and removed.

The ſtaples are counted from the left of the implement;

calling that which is neareſt to the winch of the cylinder of it the firſt. The driver is alſo conſidered as beginning on the left of the field, and making up the broken parts, on the right of the numbers, &c. by preſerving about the diſtances ſpecified in the right-hand column of the table, taking the mark of the roller for his guide. In broad-caſt work he muſt return cloſe to his former track.

It remains now to be ſhewn how, or in what manner, the grain is brought into the little furrows made by the ſhares; for this purpoſe, the funnel is divided into ſixteen compartments; and for the very ſame reaſon, to make the ſeed fall equally through the bottom, when the implement may be working on a declivity. But all the partitions are made to ſlide out, they being formed in battened grooves. This is for the purpoſe of introducing the *drill bottoms*, as they are called; one of which is for nine rows, and another for three. Each of them, it is ſaid, is nothing more than a wedge-like block, which being let down into the bottom of the funnel, fits exactly at the edges; and by means of holes of a conical form, which are ſcooped out in it, and correſponding ſmall tin ſpouts below to direct what ſeed they reſpectively receive, in a forward manner, ſhooting it, as it were, under the hollow heel of the ſhare, diſtribute the ſeed into the number of furrows which are made for receiving it.

The middle hole or ſcoop only, however, is of equal extent to the right and left of the tin ſpout; the other two ſcoops are neceſſarily of a ſomething ſhelving or ſlanting form; it being indiſpenſable to allot to each ſpout an equal ſurface on the block; and to ſhelve the ſcooping to the ſpot where its ſpout is fixed.

The drill bottoms may thus be changed at pleaſure; the partitions will keep them duly in their places. But although there are ſixteen compartments in the funnel, no more partitions are to be uſed than may be neceſſary to correſpond with the number of ſcoops and ſpouts in the drill bottom. It is to be remembered, that, as there will be ſeed falling from the whole length of the cylinder into the funnel, and that as there will be occaſionally a portion of the drill bottom parted off, which has no ſpout, ſuch compartment ſhould when neceſſary be emptied, and the ſeed be put into thoſe diviſions only of the cylinder which are over the ſpouts.

The two ſhafts of the tool are connected firmly together by a ſtrong thwart or tie, and which, when the other parts are united with it, render the whole completely ſubſtantial. Under the hinder end or part of the ſhafts, a ſcraper is carried quite acroſs, and is bolted in with the croſs piece, which has an iron edge, and ſerves to diveſt the roller of the adheſive ſoil that would otherwiſe accumulate about it. The upper and under edges in the back part of the thwart are completely rounded off, ſo as to be ſemicircular. This thwart ſhould be inſerted as cloſe as poſſible to the back of the cylinder; becauſe its purpoſe is to aid a ſheep-ſkin wrapper in lapping round under it, thus keeping the ſeed in, when the cylinder ſhould not ſow. The wrapper extends the whole way acroſs, and ſhould be about two feet deep; each edge, that is of the top and bottom, but not of the ſides, ſhould be affixed to a lath, in order to make it draw backward and forward in a ſtraight line. The place ſhould be cut to about half an inch in length, by which means it will, when paſſed under the cylinder with the wool ſide upwards, repel the ſeeds when they attempt to preſs through the perforations. This wrapper ſhould always be paſſed under, while the implement is turning at the ends of the lands; but at other times it draws over the cylinder, the fleſh ſide uppermoſt, and ſerves to keep out wind and rain. There are two little pullies affixed into the ſhafts, cloſe under the fore-board, which ſerve to paſs cords over, ſo that by the aid of the rounded back of the thwart, the wrapper may glide eaſily, either over or under. When brought round under the cylinder, its front lath hitches to two hooks, under the half foot-board, in order to prevent its receding, and to keep it tight to the cylinder. It may be noticed, that it is of more importance to keep the wrapper tighter to the front than to the back part of the cylinder; becauſe the revolution of the latter being againſt that of the ſun, the ſame as that of the roller's when viewed from the left ſide, it is obvious, it is ſaid, the grain will caſt forward, and have a tendency to relinquiſh the hinder part of the cylinder, as it riſes in that part. It is likewiſe ſuggeſted, that although the axis of the cylinder in this implement is made to paſs through the ſhafts, it would ride on them to more advantage, and render it far eaſier to ſhift the drill bottoms and the partitions in the funnel. Indeed, it is thought, that the former might be made to fit in by a flap, made to open at the bottom of the back-board.

There is a ſmall ſtiff bolt affixed to a croſs-piece, for the purpoſe of ſliding into the grooves of the bar near the cylinder, ſo as to keep it fixed, and prevent its turning either way, when preſſed by the action of the ſhares. In ſetting the ſhares to any deſired depth, by turning the winch, the bolt muſt be drawn back, otherwiſe the grooved bar cannot turn; but as ſoon as it is put to the proper depth, the bolt is to be puſhed in again to its oppoſite groove.

The ends of the cranks on the axis of the roller are ſplit like ſpring keys, and have a catch, over which the hind end of the parallel iron ſlides, and is kept in its place. This is more clearly evident in the terminations of the ſame cranks. When the cylinder of the implement is not to turn, as in paſſing from one place to another, &c. the ſprings are to be pinched together, and the parallel iron to be drawn off; which is then to be hitched up to a hook at the ſide of the driver's ſeat, which ſeat is ſupported by the ſtandards which are let into the ſhafts. The ends of the cranks might, it is ſuppoſed, be perforated and keyed, but theſe modes would not be ſo good as the plan which is here adopted.

It will be readily remarked, that by far the greater part of the machinery in this ſowing-roller relates to the drill practice of putting in the ſeed; as when it is made only to broad-caſt, nothing but the cylinder and two thin boards, forming a directing funnel, will be neceſſary. It is alſo ſuggeſted, that the great ſtrength of the fore-board, already noticed, would likewiſe be unneceſſary, as there would be no ſhares, no ſtaples, nor grooved bar; and that there would not be any occaſion for a drill bottom, though an immenſe ſaving of ſeed, and great facility of hoeing the young crops, would ariſe, it is aſſerted, from adopting ſuch a mode of committing the ſeed to the ſoil. The tin ſpouts, in ſuch caſe, it is ſuppoſed, ſhould rather point backwards than forwards; for, if unprotected by preceding ſhares, they might be liable to injury from clods, &c.; their diameter ought to be, it is ſaid, about an inch for white corn, but that for ſmall ſeeds half an inch might anſwer better and in a more perfect manner. The harrow, prepared with a ſufficient number of ſharp tines, ſuited in length to the kind of ſeed, would cover it ſufficiently; and the roller would finiſh the work in a complete manner. Thus, if corn were ſown at nine inches or a foot aſunder, it would, it is contended, be ſo little diſturbed by the harrow, as to come up in rather broad lines, but with interval enough for the free action of a ſix-inch hoe. It is farther alſo to be well noticed, that, as the roller and the cylinder each revolve in the ſame period of time, that the larger the cylinder, the more ſeed will be ſown; unleſs a ſmall one be more pierced, that is, have more holes in it, in proportion as it is ſmaller than the roller. In the proportions which have been made uſe of in the above inſtance, the roller being twenty-eight inches in diameter, its circumference will be more than ſeven feet, whereas the cylinder is but one foot in diameter, therefore little more than a yard in circumference. Conſequently, as the roller will paſs over full ſeven feet of ground, while the cylinder preſents only three feet of revolving ſurface, the latter muſt be ſo much pierced as to allow the ſeed to fall *very freely*, otherwiſe the ground will be but thinly ſown, and the buſineſs, of courſe, imperfectly performed.

The one-foot cylinder has been already conſidered, and ſuggeſted as being the moſt applicable to ſmall ſeeds, and which the conſiderations juſt ſtated ſeem more fully to confirm. They likewiſe ſeem to ſtrengthen the ſuggeſtion, that, for white corn, peas, and other ſimilar ſorts of articles, the cylinder would be more ſuitable, if it were enlarged, according to the number of pecks or other meaſures required to ſow an acre. It is a neceſſary caution that, in ſowing with this implement, the cylinder be never filled too full; it ought indeed, in no caſe, to be more than three-fifths filled, and, if only filled up to the axis of it, ſo much the better. While the ſeed is putting in, which ſhould be done by means of a ſhort, broad, tin funnel, the wrapper ſhould be paſſed under the cylinder to keep it in, as ſeen in deſcribing the tool.

It is ſuggeſted further too, that, by previouſly ſetting the centre ſhares of the implement rather higher than thoſe towards the ſides, which may be eaſily done by taking out the grooved bar, by unkeying the ſtrap by which it is held down into the box near the winch, it may be made to ſow on narrow ridges, which is very neceſſary and deſirable in different ſituations, but it will then require that a ſuitable roller ſhould be uſed; or by ſetting the middle ſhares deep, pulling off thoſe towards the ſides, the implement might be made to work with a common furrow-roller. In either caſe the points and tops of the ſhares ſhould, it is ſaid, form a curve correſponding with the ſhape of the roller, but more eſpecially where the ridges are very narrow, and much raiſed in the crown.

It is obvious, the inventor ſays, that the whole of the above ſowing apparatus is capable of being attached to any common well made *field-roller* which is of a good ſize in the barrel, and fitted into a proper frame, with a ſeat, and other neceſſaries; and that every part of the broad-caſt machinery may be connected with it at very little expence. Theſe are very important conſiderations in ſuch ſorts of tools; but, beſides, the roller will ſtill be a roller, and uſeful as ſuch; while the ſowing part, being only neceſſary when that operation is to take place, may at other times either be left at reſt, or be altogether removed.

It is ſtated in concluſion, that by means of this ſowing-roller, the work of ſowing, harrowing, and rolling may go on all at one time, and that, by a change of horſes once in the day, a field of ten acres may be eaſily ſown and finiſhed in that time. That in hot dry ſeaſons, when farmers are under the neceſſity of catching and taking the advantage of ſmart ſhowers, for the ſowing of their turnip ſeed in particular, a tool that is capable of effecting ſo much cannot but be highly uſeful. The land will not only be better and more expeditiouſly ſown, but be left in a more ſuitable ſtate for preventing the effects of the weather. It will probably too not be much leſs beneficial for the purpoſes and intentions of ſowing in other caſes.

The great power, together with the ready and extenſive application of the roller, hold out to the agricultural mechanic, means which ought not to be overlooked in the conſtruction of tools and machinery of this nature, as they afford prodigious facility in forming and giving them motion.

SOWINS, or Sowings, in the manufacture of linen-cloth, are uſed in a rather coarſe and pretty thick but not over thick ſtate, by weavers, in dreſſing and preparing their yarn of this kind for the loom, or being woven into cloth. It takes away, combines, and hardens the looſe parts of the threads or *ſleeſings*, as they are called, and gives a ſort of body to the whole divided parts of the yarn before the operation of weaving begins to be performed, and conſequently greatly facilitates the work. In this proceſs or practice the beſt flour is likewiſe ſometimes employed in the ſame way, as going farther and anſwering better, eſpecially for fine cloths.

SOWLEE, in *Geography*, a town of Bengal; 17 miles E. of Boglipour.

SOWNE, a term uſed in the exchequer; ſeeming to be a corruption from the French *ſouvenu*, *remembered*.

Such eſtreats and caſualties as the ſheriff by his induſtry cannot get or levy, are ſaid to be eſtreats that *ſowne* not, that is, are not to be remembered, or are not in demand. On the contrary, eſtreats that ſowne, are ſuch as he may gather.

SOWRAY, in *Geography*, a town of Hindooſtan, in the circar of Chanderee; 40 miles S.S.E. of Chanderee.

SOWREE, a town of Hindooſtan, in Bengal; 15 miles N.E. of Jellaſore.

SOXALÆ, or Camelobosci, in *Ancient Geography*, a people of Germany, who inhabited the vicinity of the deſerts. Ptolemy.

SOXINI, or Soccini, Mariano, in *Biography*, denominated the elder, an eminent canoniſt, was born at Siena in 1401. He ſtudied firſt at his native place, and then in Padua, in which laſt univerſity, after he had taken his degree, he was for ſome years profeſſor of the canon law. He then returned to Siena, where he taught as a profeſſor during the remainder of his life. He was very intimate with Eneas Sylvius, afterwards pope Pius II., who has written a panegyric upon him in one of his letters in the moſt magnificent terms, aſſigning to him almoſt univerſal proficiency in ſcience and the arts, with the greateſt excellence of moral character. Soxini was ſent by the ſtate to compliment Sylvius when he aſcended the papal throne, on which occaſion he was nominated conſiſtorial advocate. He died in 1467, leaving behind him a conſiderable reputation for learning and integrity. His works, conſiſting of "Conſultations," "Commentaries on the Books of Canon Law," and tracts upon "Legal Subjects," have been frequently reprinted.

Soxini, or Soccini, Bartolomeo, a celebrated civilian, ſon of the preceding, was born at Siena in 1436. He ſtudied the law under different maſters at Siena and Bologna, and after he had been admitted to a doctor's degree he became profeſſor of the civil and canon law in his native city. He was, in 1473, invited to Piſa, where he taught both branches of law, and in this city he reſided twenty years, with ſome occaſional abſences. He took an active part in the civil diſſentions of Siena, and was, at one time, in the liſt of the baniſhed citizens. He was employed in embaſſies from the Sieneſe to the Florentines, and it is ſaid he engaged in a military attempt to change the conſtitution of Siena. At Piſa the famous Jaſon del Maino was his rival, and they held frequent public diſputations, at one of which Lorenzo de Medici was an auditor. Jaſon being hard preſſed by the arguments of his antagoniſt, quoted, in his own favour, a text which he had invented for the occaſion. Soxini, with equal readineſs, invented

vented another to oppoſe it, and being aſked by Jaſon where he had found it, "Next to that which you have juſt now quoted," he replied. The fame which he had acquired cauſed him to be invited to Padua in 1489, with the offer of a large ſalary, which he determined to accept, but his intentions being known he was detained. For ſome time he was profeſſor at Padua. He died in 1507, having been three years deprived of the uſe of his ſpeech. His works as an author were "Conſultations," "Comments on the Code and Digeſt," the "Rule of Right," and other pieces of a ſimilar kind. He was not eſtimable as a practical moraliſt. He was addicted to gambling, and would ſometimes leave his ſcholars without a leſſon, and paſs whole nights at the gaming table, the conſequence of which moſt deſtructive habit was, that he did not leave money enough behind him to pay the expences of his funeral. He was extremely greedy of money, charged very high for his opinion, which he would ſometimes give to both parties in a ſuit. He was free of ſpeech, ſarcaſtic and jocular. His faults were borne with on account of his high profeſſional character. Angelo Politiano, ſpeaking of his intended correction of the Pandects, ſays, "I muſt have recourſe to the aſſiſtance and advice of that ſingularly excellent doctor of Siena, Bartolomeo Soxini, whom I may boldly denominate the Papinian of our age."

Soxini, Mariano, denominated the younger, grandſon of the firſt Mariano, was born at Siena in 1482: he ſtudied the law under his uncle Bartolomeo, and after taking his degree, taught alternately the civil and canon law at his native city, till he removed to Paris in 1517. Returning to Siena in 1524, he was employed as ambaſſador to the republic of Florence, and alſo to pope Leo X. He was engaged in the following year by the republic of Venice, to occupy a profeſſorſhip at Padua. He remained at that univerſity till the year 1542, when the offer of a higher ſalary drew him to Bologna. Here he continued till his death, though he received the moſt flattering invitations, with the promiſe of large ſalaries, from Coſmo, duke of Florence, the king of Portugal, and other princes and ſtates. He died in 1556, and his German ſcholars in Bologna ſhewed their reſpect for his virtues and talents, by carrying his body on their own ſhoulders to the tomb. He was author of many works, which were once in conſiderable eſtimation, though they are now forgotten.

Soxini, Lelio, ſon of the preceding, was born at Siena in the year 1525. He was deſtined by his father for the legal profeſſion, but having in the courſe of his ſtudies attended to ſcriptural truths, he felt reaſon to queſtion the validity of the doctrines of the Catholic church. For the purpoſe of farther enquiry, he made himſelf acquainted with the languages in which the Old and New Teſtament were written, alſo with the Arabic and other oriental languages. About the year 1546 he joined himſelf to a ſociety attached to the principles of reformation in religion, and the members of which ſpeculated very freely on the myſteries contained in the doctrines of the Trinity, and the atonement. Their objects being diſcovered, ſome were apprehended, and others gladly fled from the iron arm of perſecution. Two of thoſe who fell into the hands of the prieſts ſuffered death as heretics, and thoſe who remained concealed themſelves, or withdrew into foreign countries. The ſubject of this article quitted Italy in 1547, and travelled during the four following years into France, England, Germany, and Poland. He then fixed at Zurich, where he maintained a correſpondence with the reformers in various parts of Europe, by whom he was held in high eſteem, till he ſhewed a leaning to the doctrines of Arianiſm. Calvin, who was ever eager in detecting hereſy, wrote him a letter of admonition, which was followed by a ſtill ſtronger warning, the burning of Servetus, and which was ſufficient to deter Lelio from taking a very active part in propagating the doctrines to which he adhered. On the death of his father, in 1556, he obtained letters of legation from the king of Poland to Venice and Florence, which enabled him to ſettle the affairs of his inheritance. He died in 1562. He was mild and gentle in diſpoſition, averſe from all controverſy, and was evidently led by conſcience to differ from thoſe with whom he lived. Some writings have been attributed to him, but critics are very doubtful as to what he really wrote. Bayle.

SOYDE, in *Geography*, a town of Norway; 36 miles N. of Stavanger.

SOYDPOUR, a town of Bengal; 25 miles S.W. of Silhet.

SOYLAND, a townſhip of the pariſh of Halifax, Yorkſhire. See Halifax.

SOYOLLA, the principal iſland of a cluſter in the Red ſea. N. lat. 14° 2′. E. long. 59° 38′.

SOYON, a town of France, in the department of the Drôme, on the Rhone; 6 miles S. of Valence.

SOZ, a river of Ruſſia, which runs into the Dnieper, 16 miles S. of Bilitzi, in the government of Mogilev.

SOZO, in *Ancient Geography*, a town of Aſia, in the interior of Media. Ptolemy.

SOZOMEN, Hermias, in *Biography*, an eccleſiaſtical hiſtorian, contemporary with *Socrates* (ſee his article), was born of reſpectable parents, as ſome ſay at Salamis, in the iſle of Cyprus, but according to others, at Gaza or Bethelia, in Paleſtine. Having ſtudied the law at Berytus, he practiſed as an advocate at Conſtantinople, devoting his leiſure hours to the compoſition of his eccleſiaſtical hiſtory. This work contains, in nine books, an account of the affairs of the church, from the third conſulſhip of Criſpus and Conſtantine, Cæſars, to the 17th conſulſhip of Theodoſius the emperor, in whoſe time he wrote, and to whom he dedicated his performance; that is, from the year 324 to the year 439, or during a period of 115 years. Cave repreſents him as flouriſhing about the year 440. In his hiſtory, which is written in a more florid and elegant ſtyle, but with leſs judgment, than that of Socrates, he has introduced many eulogiums of a monaſtic life, to which he was attached in conſequence of his education among monks, and he has added many narrations of the actions and manners of the recluſe, and his teſtimony to the early practice of public penance in the Roman church, together with a detail of the particular ceremonies of which it conſiſted. To the orthodox, however, he has given offence by his commendations of Theodore of Mopſueſta, with whom originated the hereſy of two perſons in Chriſt. His hiſtory is chargeable with ſeveral notorious errors in the relation of facts. He is ſuppoſed to have died about the year 450. Sozomen's hiſtory is printed with that of Socrates, and the other Greek eccleſiaſtical hiſtorians. A work of Sozomen, not now extant, containing, in two books, a ſummary account of the affairs of the church, from the aſcenſion of Chriſt to the defeat of Licinius, was written before his hiſtory. In moderation and candour Sozomen reſembled Socrates; and it is true of the former, as well as the latter, that he always ſpeaks with great reſpect of the ſacred ſcriptures. Dupin. Lardner.

SPA, or Spaw, in *Geography*, a town of France, in the department of the Ourte, belonging to the biſhopric of Liege, in Germany, and ſituated in the marquiſate of Franchimont, on a ſmall river which runs into the Ourte. It was formerly a ſmall village, but ſince the diſcovery of its mineral waters, about the year 1326, and the celebrity which they have acquired, it has been conſiderably enlarged; and now conſiſts of two ſtreets, joined by a bridge over the ſtream that runs through it, together with ſeveral ſmaller ſtreets and rows of houſes; thoſe of more ancient date being irregularly arranged, and conſtructed of wood and plaſter, and the more modern built with brick and ſtone. The ſoil about the town is rocky, gravelly, or loamy, intermixed more or leſs with iron ore. The country about it abounds with hills and woods, ſo that it is not fertile in grain, but it has plenty of ſheep, kine, and poultry, and great quantities of game, and the ſtreams furniſh an ample ſupply of various kinds of fiſh. During the ſeaſon in which the waters are uſed, the town reſembles a fair in its variety of booths, toys, &c. Its vicinity affords pleaſant and ſalubrious rides, and many agreeable and romantic walks: and its viſitors are gratified with evening amuſements in public rooms adapted for this purpoſe. Some have ſuppoſed that the medicinal waters of this place are thoſe that are mentioned by Pliny in his "Natural Hiſtory," but others apprehend that thoſe were the waters of Tongrés. Theſe waters were at firſt the property of the community of Spa, but they were afterwards taken poſſeſſion of by a biſhop of Liege, until an appeal was made to the imperial chamber, which reſtored them to the original proprietors, who impoſe a ſmall duty on every flaſk exported under their ſeal. In the year 1794, Spa was taken by the French; 16 miles S.E. of Liege. N. lat. 50° 31′. E. long. 5° 30′. The waters are furniſhed by various ſprings. Thoſe of the Pouhon ſpring have been preferred, by our chief phyſicians, to any others in or near the country of Liege; particularly to the waters of Bru, which they complain have been impoſed on the public, to their and their patients' frequent diſappointment.

However, as the Spa waters are impregnated with different proportions of the ſame ingredients, they may be choſen differently, according to the intentions with a view to which they are uſed. The Pouhon is the ſtrongeſt chalybeate. This is in its moſt perfect and natural ſtate in cold dry weather; but in warm moiſt weather it loſes its tranſparence, appears turbid or wheyiſh, contains leſs fixed air, or carbonic acid gas (ſee CARBONIC *Acid*), and is partly decompoſed. This water, which is colder by many degrees than the heat of the atmoſphere, is ſuppoſed to contain the greateſt quantity of fixed air of almoſt any acidulous water; and in conſequence of this ingredient, it has a remarkable ſprightlineſs and vinoſity, and boils by mere warmth; but this ſoon flies off if the water be left expoſed, though it may, in a great meaſure, be preſerved in well-corked bottles. It is capable of diſſolving more iron than it naturally contains, and of thus becoming a ſtronger chalybeate, on account of the great quantity of fixed air which it contains: and for the ſame reaſon an ebullition is raiſed in it on the addition of acids, which diſengage its fixed air. This water mixes ſmoothly with milk, whether it be cold or of a boiling heat.

The Tonnelet and Geronſterre waters are weaker chalybeates, but briſker and more ſpirituous. The Groeſbeck, Sauveniere, and Wartroz, are ſtill weaker chalybeates, but highly impregnated with calcareous and ſelenitical earths, and contain alſo a greater proportion of the foſſile alkali. The Geromont is likewiſe a weak chalybeate, but contains a great deal of calcareous and ſelenitical earths, and about three times as much alkaline ſalt as any of the others. The four laſt waters, therefore, will be better in diſorders ariſing from an acid cauſe, and as diuretics, particularly the Geromont. The Bru, or Churon water, approaches to the nature of the Tonnelet, and though it has been decried, is ſaid, in conſequence of every trial, not to be inferior to any of the Spa waters.

All the waters that are comprehended under this denomination, abound with fixed air; they alſo contain more or leſs iron, foſſile alkali, and calcareous and ſelenitical earths, together with a ſmall portion of ſea-ſalt, and an oily matter common to all waters. All theſe ingredients are kept ſuſpended, and in a neutral ſtate, by means of the fixed air, on which the virtues chiefly depend; though they are probably rendered more active and penetrating, both in the firſt paſſages, and alſo when they enter the circulation, by means of that ſmall portion of iron, earth, ſalt, &c. with which they are impregnated.

Theſe waters are diuretic and ſometimes purgative; and, like other chalybeate waters, they tinge the ſtools black. They exhilarate the ſpirits much better than wine or ſpirituous liquors, and their general operation is by ſtrengthening the fibres. They cool and quench thirſt much better than common water.

They are found excellent in caſes of univerſal languor or weakneſs, proceeding from a relaxation of the ſtomach, and of the fibres in general, and where the conſtitution has been weakened by diſeaſes, or by a too ſedentary life; in weak, relaxed, groſs habits; in nervous diſorders; at the cloſe of fits of the gout and rheumatiſm; in ſuch aſthmatic diſorders and chronic coughs as proceed from too great a relaxation of the pulmonary veſſels; in obſtructions of the liver and ſpleen; in ſcorbutic and other putrid diſorders; in hyſterical and hypochondriacal complaints; in paralytic diſorders; in gleets; in the fluor albus; in fluxes of the belly; in the gravel and ſtone; in female obſtructions; in barrenneſs; and in moſt other caſes where a ſtrengthening and briſk ſtimulating reſolving chalybeate remedy is wanted: but they are generally hurtful in hot, bilious, and plethoric conſtitutions, when uſed before the body is cooled by proper evacuations; they are alſo hurtful in caſes of fever and heat, in hectic fevers, and ulcerations of the lungs, and of other internal parts, and in moſt confirmed obſtructions attended with fever. The uſual ſeaſon for drinking them is in July and Auguſt, or from May to September. The quantity to be drank is ſuch as the ſtomach can bear without heavineſs or uneaſineſs: but it is adviſeable to begin with drinking a glaſs or two ſeveral times in a day, and ſo increaſe the quantity daily, as the ſtomach can bear; and during the courſe to continue that doſe, and to diminiſh the quantity at the cloſe in the ſame degree as it was augmented at the beginning. Moderate exerciſe is proper after drinking. Previous to the uſe of the water, the firſt paſſages ſhould be cleanſed by gentle purges, and, if neceſſary, an emetic ſhould be given; and during the courſe, coſtiveneſs ſhould be prevented, by occaſionally adding Rochelle ſalts or rhubarb to the firſt glaſſes of water in the morning; and a cooling regimen ſhould be obſerved.

The Spa water is alſo uſed externally, in a variety of caſes, with good ſucceſs. It is uſed as an injection in the fluor albus, and in ulcers and cancers of the womb, and alſo in the gonorrhœa; it is ſerviceable for waſhing venereal aphthæ, and ulcers in the mouth, phagædenic ulcers, by way of gargle for relaxed tonſils, and for faſtening looſe teeth, and in other caſes of relaxation. It is alſo ſaid to cure the itch, and ſimilar complaints, by waſhing and bathing, an internal courſe being obſerved at the ſame time. Elliott's Mineral Waters, p. 201, &c.

The town of Spa being reſorted to by perſons from all parts of Europe, on account of its waters, has always been allowed a neutrality during the hotteſt wars.

SPAAD, or Spalt, *Spatum*, a word uſed in ſeveral different ſenſes; ſometimes for a ſpecies of Engliſh fibroſe talc, or of gypſum; and ſometimes for ſpar.

The various kinds of ſpaad are found pretty frequently in England and Germany, and ſometimes brought from the Levant: they are all ſoft, and eaſily pulverized.

SPACE, Spatium, a ſimple idea, the modes of which are diſtance, capacity, extenſion, duration, &c.

Space, conſidered barely in length between any two bodies, ſuggeſts the ſame idea which we have of diſtance.

If it be conſidered in length, breadth, and thickneſs, it is properly called *capacity*.

When conſidered between the extremities of matter, which fills the capacity of ſpace with ſomething ſolid, tangible, and moveable, it is then called *extenſion*.

So that extenſion is an idea belonging to body only; but ſpace, it is plain, may be conſidered without it.

Space, therefore, in the general ſignification, is the ſame thing with diſtance conſidered every way, whether there be any ſolid matter in it or not.

Each different diſtance is a different modification of ſpace; and each idea of any different ſpace is a ſimple mode of this idea. Such are an inch, foot, yard, &c. which are the ideas of certain ſtated lengths, which men ſettle in their minds for the uſe, and by the cuſtom of meaſuring. When theſe ideas are made familiar to men's thoughts, they can in their minds repeat them as often as they will, without joining to them the idea of body, and frame to themſelves the ideas of feet, yards, and fathoms, beyond the utmoſt bounds of all bodies; and by adding theſe ſtill to one another, they can enlarge their idea of ſpace as much as they pleaſe.

From this power of repeating any idea of diſtance, without being ever able to come to an end, we acquire the idea of immenſity.

Another mode, or modification, of ſpace, is taken from the relation of the parts of the termination of extenſion, or circumſcribed ſpace, amongſt themſelves; and this is what we call *figure*. This the touch diſcovers in ſenſible bodies, whoſe extremities come within our reach; and the eye takes, both from bodies and colours whoſe boundaries are within its view; where, obſerving how the extremities terminate, either in ſtraight lines, which meet at diſcernible angles, or in crooked lines, in which no angles can be perceived; by conſidering theſe as they relate to one another, in all parts of the extremities of any body or ſpace, it acquires the idea we call figure, which affords to the mind infinite variety.

Another mode belonging to this head is that of *place*; which ſee.

Another mode of ſpace is the idea which we get from the fleeting, and perpetually periſhing, parts of ſucceſſion, which we call *duration*.

Space is uſually divided into *abſolute* and *relative*.

Space, *Abſolute*, is that conſidered in its own nature, without regard to any thing external, which always remains the ſame, and is infinite and immoveable.

Space, *Relative*, is that moveable dimenſion or meaſure of the former, which our ſenſes define by its poſitions to bodies within it; and this the vulgar uſe for immoveable ſpace.

Relative ſpace, in magnitude and figure, is always the ſame with *abſolute*; but it is not neceſſary it ſhould be ſo numerically: as if you ſuppoſe a ſhip to be, indeed, in abſolute reſt, then the places of all things within her will be the ſame abſolutely and relatively, and nothing will change its place; but ſuppoſe the ſhip under ſail, or in motion, and ſhe will continually paſs through new parts of abſolute ſpace; but all things on board, conſidered relatively, in reſpect to the ſhip, may be, notwithſtanding, in the ſame places, or have the ſame ſituation and poſition, in regard to one another.

The Carteſians, who make extenſion the eſſence of matter, aſſert, that the ſpace any body takes up, is the ſame thing with the body itſelf; and that there is no ſuch thing as mere ſpace, void of all matter, in the univerſe; but this ſee diſproved under Vacuum.

The Carteſians, who do not allow of any diſtinction between ſpace and matter, were naturally enough led to the opinion, that ſpace or extenſion was a ſubſtance. Others, who admit a vacuum, and conſequently an eſſential difference between ſpace and matter, aſſert alſo that ſpace is a ſubſtance. Among theſe we find s'Graveſande, Introd. ad Philoſ. ſect. 19.

Others put ſpace into the ſame claſs of beings as time and number; that is, they make it to be no more than a notion of the mind. Hence, according to theſe authors, abſolute ſpace, of which the Newtonians ſpeak, is a mere chimera. See the writings of the late biſhop of Cloyne, paſſim.

Space and time, according to Dr. Clarke, are attributes of the Deity, and the impoſſibility of annihilating theſe, even in idea, is the ſame with the neceſſary exiſtence of the Deity. See Watt's Phil. Eſſ. Eſſ. i.

Space, in *Geometry*, denotes the area of any figure; or that which fills the interval or diſtance between the lines that terminate it.

The *parabolic* ſpace is that included in the whole parabola.

The *conchoidal* ſpace, or the *ciſſoidal* ſpace, are what are included within the cavities of the conchoid and ciſſoid. By the new methods now introduced, of applying algebra to geometry, it is demonſtrated, that the conchoidal and ciſſoidal ſpaces, though infinitely extended, are yet finite magnitudes.

Space, *Cycloidal*. See Cycloidal.

Space, *Elliptic*. See Elliptic.

Space, in *Mechanics*, the line a moveable body, conſidered as a point, is conceived to deſcribe by its motion.

SPADA, Lionello, in *Biography*, was born at Bologna in 1576, in a very low condition of life; and when a boy he became the ſervant of the Caracci, and ground and prepared their colours. The conſtant opportunity he poſſeſſed, whilſt with theſe great men, of ſeeing pictures, and hearing diſcuſſions on the principles of the art, rouſed a latent diſpoſition to ſtudy and deſign, which his maſters ſaw and encouraged; and at length they admitted him into their academy, where they had the gratification of ſeeing him become one of their moſt eminent diſciples; though he never arrived at any very great degree of grandeur or purity of invention. His ſtyle is a compound of the Caracci and Caravaggio's manners, and is wrought with great boldneſs. His principal productions are, The Miraculous Draught of Fiſhes, in the refectory of S. Procolo at Bologna, and St. Dominic burning the forbidden Books, for the church of that ſaint, in the ſame city. This laſt is conſidered as his very greateſt work. The latter part of his life was paſſed at Parma, in the ſervice of the duke Ranuccio. He died in the 46th year of his age, in 1622.

Spada, in *Geography*, a cape of the iſland of Candia; 24 miles N.W. of Canea.

SPADE, in *Agriculture* and *Gardening*, a well-known ſort of tool, employed in digging the land. There are ſeveral forms and kinds of them in uſe for different purpoſes, as thoſe of common digging, draining, and making of earth fences,

fences and embankments of different ſorts, as well as many others, in the former of theſe arts. The moſt handy and convenient form of them, for common work, is probably that in which they are made ſtrong in the back, and have a ſlight bend or curve in the handle or ſhaft, as by means of this the labour is performed with greater eaſe and facility. Various forms, ſhapes, and ſizes of ſpades are had recourſe to in performing the operations of draining, mound-fencing, and embanking, according to circumſtances; as well as in particular works of other kinds. See Spade, *Draining*.

The ſpade is alſo an uſeful garden implement, which is uſed for digging and preparing the ſoil for the reception of all ſorts of ſeeds and plants. There are ſeveral ſorts and ſizes of ſpades occaſionally employed in this art, though the common large digging ſpade is, in moſt places, almoſt commonly uſed for all kinds of digging and ſpade-work, which, however, in many inſtances, cannot be ſo conveniently uſed as a middling or ſmall ſpade; it is, therefore, eligible for every garden to be furniſhed at leaſt with three different ſizes of ſpades, to ſuit every department of gardening the more commodiouſly; ſuch as the common large digging ſpade, for all common digging and ſpade-work; a middling and a ſmall ſpade, for digging particular narrow compartments, and between ſmall plants cloſely placed in beds and borders, &c.

The firſt ſort is uſually from fourteen to fifteen inches long in the plate, and nine broad, narrowing gradually half an inch or an inch leſs at the bottom. The ſecond ſort ſhould be about a foot long in the plate, and ſeven or eight inches broad. The ſmall ſpade, which is about eight or nine inches long in the plate, and five wide, is convenient in pointing up or ſlight digging, and in freſh looſening the ſurface between cloſe-placed ſmall plants, in beds and borders, &c. where neither of the two former ſpades can be readily introduced: it is alſo uſeful in planting and potting many ſorts of ſmall plants, taking up ſmall roots, and other light purpoſes.

And other ſorts are likewiſe in uſe for different purpoſes, as a very ſmall narrow ſpade, having the plate about ſeven inches long, by three and a half or four wide, which is very uſeful in ſmall compartments of beds, borders, &c. containing ſome particular cloſe-placed, ſmall plants of flowers, and others, both in occaſionally ſlightly digging, or looſening the earth between them with greater eaſe and effect, than a larger ſized ſpade; alſo ſometimes in ſimilar compartments, in occaſionally trimming round the bottom part of ſome ſtraggling fibrous-rooted plants; and it is alſo often uſeful in taking up and tranſplanting ſmall plants, and taking off root offsets and ſlips, in particular ſorts, in which a larger ſpade would not be ſo convenient. And further, a ſemicircular or ſcooped ſpade is another ſort of a ſmalliſh ſize, having the plate made hollow, like a ſcooped garden-trowel, which is very uſeful in taking up ſmall plants with balls of earth, to preſerve the ball more firmly about the roots.

Proper garden-ſpades have the plates wholly of iron, not above a quarter of an inch thick upward, growing gradually thinner from the middle downward; the tree, or handle, being generally of aſh, about two feet long, and an inch and half thick, with a firm open handle at top, formed out of the ſolid wood, juſt big enough to admit of taking ready hold.

Spade, *Draining*, that ſort which is employed for the purpoſe of cutting out field drains. Spades for this uſe are made of different breadths, ſo as to follow each other, and cut the drains narrow at the bottoms. There are uſually a top or upper, middle, and pointed bottom ſpade made uſe of in this work.

And there is a ſort of ſpade or ſhovel, which is turned up on the ſides, that is uſeful in taking out the ſmall pieces of earth from the bottoms of the drains. Likewiſe a ſpade or tool of the ſcoop kind.

Alſo a wooden ſpade, employed in ſoft peaty ſoils, where the common draining-ſpades cannot be uſed. See Spring and Surface-*Draining*.

Spade, *Paring*, that ſort of ſpade which is made uſe of in removing the ſward from graſs-land. See Paring *Spade*, and Shovel.

Spade, *Turfing*. See Turfing.

Spade alſo denotes any gelded beaſt, or a deer three years old.

Spade-*Bit*, the quantity of earth raiſed by the ſpade in one effort. Hence probably *ſpit*. It alſo ſignifies the broad iron part of the ſpade.

Spade-*Bone*, a term provincially applied to the ſhoulder-bone, probably from its being uſed formerly as a ſpade.

Spade *Land*, *To*, provincially to pare ground, or breaſt-plough it.

SPADICEOUS, or Spathaceous *Plants*, in *Gardening*, thoſe the flowers of which are protruded or produced from a ſort of ſcabbard, or ſheath, which is burſt open. There is a great number of flower, as well as other garden-plants, which are of this ſort, as of the former, the narciſſus or daffodil and jonquil, the lily daffodil, the Guernſey lily, the aſphodel lily, the ſea daffodil, the different varieties of crocus, the meadow ſaffron, the common ſnow-drop, the leucoium, or greater ſnow-drop, and many others; and of the latter, the onion, the leek, the garlick, and ſome others.

Theſe are, for the moſt part, uſeful and valuable plants in either the common or flower-garden.

SPADING, in *Agriculture*, a term applied, in ſome diſtricts, to the practice of taking off the ſward or ſurface of graſs-land by means of the paring-ſpade, in the view of burning it. It is a method which is by no means unuſual in many diſtricts, though the paring-plough mode is by far the moſt cheap and convenient. In the county of Devon, when the ſpading of the ſurface of a field or portion of land is determined upon in this intention, it is pared off, in a clean manner, to the extent of from three-fourths to one inch in thickneſs; the ſlices of which are then ſet up edgeways, and when dry, collected into heaps, or what are provincially termed beat-barrows; and by the aſſiſtance of furze, fern, heather, hedge-row, and copſe faggots, or ſome other ſimilar material, the whole pared ſubſtance ſet fire to and reduced to a maſs of aſhes, which, when cool, are ſpread, either with or without being mixed with other matters, ſuch as lime, good mould, or the ſcrapings of roads, as the circumſtances of the caſes may require, over the land in an equal and exact manner. In this way coarſe graſs-lands are ſometimes brought into a ſtate of cultivation, and wheat, as well perhaps as ſome other crops, in different inſtances, well prepared for and got into the ground. See Paring and Burning, and Sod-*Burning*.

It is, however, a tedious and laborious method of cultivating and preparing land, which can probably be only practiſed in particular ſituations and circumſtances.

The paring-plough, which is deſigned to be introduced in the place of the tool employed in this ſort of work, and which is much ſuperior in the facility, expedition, and manner in which it performs it, has a wide-winged flat ſhare, that meaſures about fourteen inches from the land-ſide to the angular point of its right ſide, or cutting wing. In the beam part of this implement, and preceding a ſharp comb, which is welded on to the coulter-margin of the ſhare, is a ſliding-foot, fixed in ſuch a manner as to regulate the exact thickneſs of the ſlice which is meant to be pared off, with great preciſion. And the ſhare and comb of the tool being kept very ſharp by frequent grinding, enable it to perform the paring of the graſſy, or other ſurface, in a very perfect manner. This implement is held in an horizontal manner when at work, ſo as to cut a ſmooth and even furrow at the bottom part; whereas the tool uſually made uſe of is held in an oblique direction, ſo as to cut the ſpine or green ſward to a feather-edge on the furrow ſide, the whole of which is to be gradually lifted up, and turned, with its green ſide, perfectly underneath. The work is performed, in theſe caſes, by what is commonly called ſplitting or dividing. See SPLITTING.

SPADIX, in *Botany* and *Vegetable Phyſiology*, a flower-ſtalk, whether ſimple or branched, included within a *Spatha*, or Sheath. Such occurs in the natural order of *Palmæ*, which tribe Linnæus principally had in view in the technical uſe of this term. Indeed the word, which is Greek, σπαδιξ, *palmes* of the Latins, is almoſt excluſively applied by the ancients to the very ſame thing, the branched fruit-ſtalk of the date-palm. Linnæus, however, extends it to the *Arum* family, by a very fair analogy, though in that tribe it is unbranched; and by a further ſtretch of analogy, to *Acorus*. In ſome of the *Liliaceæ*, compoſing his *Spathaceæ*, though he uſes the term *Spatha*, he does not employ that of *Spadix*. Juſſieu and his followers have perhaps done well in excluding the *Spatha* itſelf from making a part of the generic character, in the natural family laſt-mentioned, though they retain it, as well as *Spadix*, in the *Palmæ*. The *Spadix*, like other flower-ſtalks, is ſolely deſtined to bear the flowers and fruit, and when the latter is perfected, the part in queſtion withers and falls off. See FRUCTIFICATION, CALYX, PALMÆ, and SPATHA.

SPADO, among the Romans, differed from an eunuch only in this, that the latter was deprived both of the penis and teſtes, but the ſpado of the teſtes only.

SPAFFORD, in *Geography*, a townſhip of America, in New York, ſituated in the S.W. extremity of Onondaga county, 13 miles S. of Onondaga; bounded N. by Marcellus and Otiſco, E. by Tully, S. by Preble in Cortlandt county, W. by the Skeneateles lake, or the county of Cayuga. It was erected in 1811, from the N.W. quarter of the military townſhip of Tully, and its population is included in that of Tully. Its area is about five miles ſquare; the central part has an extenſive valley of fine land, extending N. and S., the eaſtern and weſtern extremes being hilly. The ſoil is chiefly a ſtrong and productive loam; the timber, maple, beech, baſs or tilia, butter-nut, and a variety of other kinds. It is well watered by ſprings and brooks, and has ſome ſmall ſtreams for mills, the largeſt of which is the inlet of Otiſco lake. The firſt ſettlements were made about the year 1806, and the inhabitants are farmers from the eaſtern ſtates. Here are two or three mills, and as many ſchool-houſes, in which are alſo held the meetings for worſhip. Spafford compriſes as much of the military townſhip of Sempronius as lies E. of Skeneateles lake.

SPAGIRIC, an epithet given to chemiſtry; which is called the *ſpagiric art*, or *medicina ſpagirica*; and to chemical phyſicians, who are alſo called *ſpagiriſts*.

It is chiefly reſtricted to that ſpecies of chemiſtry which works on metals, and is employed in the ſearch of the philoſopher's ſtone.

Voſſius derives the word from σπαω, *to extract*, and αγειρειν, *congregare, to collect*; which are the two principal offices of chemiſts. Paracelſus firſt introduced the word.

SPAGIRICAL PHYSICIANS. See PHYSICIANS.

SPAGNOLETTO, IL, in *Biography*, the cognomen of a Spaniſh painter, a native of Xativa, in Valencia, whoſe real name was Joſef Ribera. He ſtudied for a ſhort time under Ribalta; but, before he was ſixteen, determined upon viſiting Italy, to cultivate his taſte, and exerciſe his talents in the art he had ſolicited for ſtudy, although he had no other means of ſupport than what he could obtain by the exerciſe of his juvenile powers. It was in the 17th year of his age, in 1606, that he arrived at Naples, where he was captivated by the ſtriking and powerful ſtyle of M. A. Caravaggio, whoſe favour he courted and obtained; and by whom he was encouraged and inſtructed during his reſidence in that city. From Naples he went to Parma, to ſee and ſtudy the works of Correggio, and thence to Rome, attracted by the reputation of Raphael and Michael Angelo; and although the influence of the ſtyle of Caravaggio ſtill predominated in his productions, yet it was not without conſiderable refinement in feeling, obtained by contemplation of the works of thoſe great men.

After a ſhort reſidence at Rome, he returned to Naples, where his proſpect of employment was much more favourable, partly from the number of excellent artiſts then practiſing in the former city, and probably more from the connection between the court of Naples and that of his own country, and its natural partiality to Spaniards. He was there taken under the protection of the viceroy, and employed in ſeveral conſiderable works, which were ſent into Spain. The principal among thoſe detained at Naples are, the Martyrdom of St. Jannarius, in the royal chapel; St. Jerome and St. Bruno, in the church of the Trinita delle Monache; and the taking down from the Croſs, at the Carthuſians.

The ſubjects he choſe for the employment of his pencil are generally of a ſevere or gloomy nature, and his colouring and execution correſpond with their character; being free and bold in ſtyle, and dark and ſtrong in hue and arrangement of light and ſhade. He died in 1656, at the age of 67. He ſometimes indulged himſelf in engraving, and has left about twenty plates of etchings, executed in very much the character of his pictures.

SPAHIS, from the Perſian *eſpawhee*, q. d. *horſeman*, called alſo *Spaogians*, horſemen in the Ottoman army; chiefly raiſed in Aſia.

The great ſtrength of the grand ſeignior's army conſiſts in the janizaries, who are the foot, and the ſpahis, who are the horſe. The aga, or commander of the ſpahis, is called *ſpahilar agaſi*. See AGA.

The ſpahis are the flower of the Turkiſh cavalry, and make a part of the grand ſeignior's guard. They are compoſed of young men brought up in the ſeraglio, of ſoldiers taken from among the janizaries, and others who have diſtinguiſhed themſelves. The ſpahis are ſpread over all the towns, and more particularly in the country places; they are almoſt all married and ſettled; they exerciſe different profeſſions, or ſometimes apply themſelves to the culture of the land; they receive a daily pay, have their appropriate officers, and aſſemble at the firſt order, armed and equipped, under the colours of their diſtrict. Theſe are a more ancient corps than the janizaries; their pay is greater; and they are underſtood to be the ſons of Muſſulmans in a certain degree of affluence; they fight under the ſame enſigns as the ziamets and timariots, and ought to ſucceed them in the poſſeſſion of their fiefs, if the regulations of the firſt ſultans were more reſpected, or the national intereſt a little more conſulted. Under the firſt ſultans, the ſpahis formed the principal ſtrength of the Ottoman armies. Almoſt always in the field, familiarized to military exerciſes, hardened to the fatigues of war, ſtimulated by intereſt, glory, religious fanaticiſm, and the example of the ſultan, it is not ſurpriſing that nothing ſhould withſtand their arms, and that the modern Greeks, enervated by luxury and riches, ſolely occupied by intrigues and idle ſpeculations, ſhould be as ſoon ſubjugated as conquered. The "Timari-ſpahis," who are much more numerous, ſerve in conſequence of their poſſeſſing a "timar," or fief, on condition of bringing into the field a certain number of men, in proportion to the ſtrength of it. Theſe poſſeſſions deſcend to their children or heirs, when of an age to ſerve; otherwiſe, they are given to others, and ſometimes, as a recompence, to old ſoldiers. See Timar, and Timariots.

SPAID, or Spayd, a term uſed by ſportſmen for a red male deer three years old.

SPAIN, in *Geography*, a country of Europe, ſituated between the 36th and 44th degrees of N. lat., and having its weſtern extremity about 9° W. long. from London. Its greateſt length from weſt to eaſt is about 600 miles, and its breadth from north to ſouth is more than 500; ſo that it forms, if Portugal be included, almoſt a compact ſquare, and is ſurrounded on all ſides by the ſea, except where the Pyrenæan range of mountains preſents a grand natural barrier againſt France. The preciſe weſtern boundary is formed by the river Bidaſoa, and the iſle of Pheaſants is near its mouth. The laſt town in Spain is Irum, near the Bidaſoa. Excluding *Portugal* (which ſee), the boundaries betwixt theſe two kingdoms depend more on artificial conventions than on rivers or mountains. The ſuperficial contents of Spain have been eſtimated at about 148,000 ſquare miles. It lies between the fifth climate on the ſouth, and half-way between the ſixth and ſeventh on the north; the longeſt days are, therefore, 14½ hours in the ſouthern part, and 15½ in the northern.

The firſt known diviſion of Spain, into Hiſpania Citerior and Ulterior, took place under the Romans; but theſe were ſoon denominated Luſitania, Bœtica, and Tarraconenſis. (See Hispania.) Luſitania comprehended the eaſtern part, and extended as far as the Atlantic ocean: its limits were marked on the north by the Duero, on the ſouth by the Guadiana, and from one to the other by a ſtraight line drawn from Simancas to Puente de l'Arzobiſpo, and from thence as far as the country of the people called Oretani, in which the town of Almagro at preſent ſtands. It included in its extent the towns of Avila, Salamanca, Coria, the territory of Plaſencia, Truxillo, Merida and Portugal, the kingdom of Leon, and part of Eſtremadura. See Lusitania.

Bœtica was almoſt ſurrounded on two of its ſides by the Guadiana, bounded on the ſouth by the Mediterranean and the ocean, and terminated on the eaſt by a line drawn from Murgis or Muxacra, a village near the ancient promontory of Charidemus, now called the Cape de Gatte, to the territory of Caſtulo, which was nearly in the ſame ſituation as the modern Cazlona, and to the country of the Oretani. It formed what is called Andaluſia, containing the kingdoms of Seville, Jaen, Cordova, and Granada; it alſo included a part of modern Eſtremadura, and extended as far as Badajoz, which was within its boundaries. See Bœtica.

Hiſpania Tarraconenſis comprehended all the other parts of Spain, and was the ſame with that called Citerior Spain. See Hispania.

The diviſion of Spain, now ſtated, underwent ſome alterations under the laſt Roman emperors, and was totally changed after the invaſion of the northern nations. It was ſubjected by the Vandals about the year 415, after the Romans had maintained poſſeſſion of it for about five centuries; and the Viſigoths, under Euric, ſubdued the whole of Spain, excepting Galicia, which was held by the Suevi, who had entered into the country with the Vandals. With this conqueſt, which occurred A.D. 472, commence the modern kingdom and hiſtory of Spain. The Arabs, or Moors, began their conqueſt A.D. 709, and ſoon extended it over the whole of Spain, except the mountains of Aſturias, where, as well as in Biſcay, king Pelagius maintained a limited dominion. The deſcendants of Pelagius, who fixed the royal reſidence at Oviedo, which was built in 761, defended their own ſmall territory, and recovered Galicia, and part of Leon and Caſtile. In the year 914, the kings, as their territory extended towards the ſouth, began to reſide at Leon, from which they took their title; and in the 11th century, *viz.* A.D. 1117, that of Caſtile was added, the kings of Caſtile having become kings of Leon and the Aſturias A.D. 1037. In 1162 the county of Barcelona was transferred to the king of Aragon, whoſe royalty commenced A.D. 1035. The ſmall kingdom of Navarre, the capital of which was Pampeluno, commenced, as ſome ſay, A.D. 857, or, according to others, under Fortunio I. A.D. 880. The reign of Alphonſo the Wiſe began A.D. 1252, and was diſtinguiſhed by the protection which it afforded to the arts and ſciences. Nevertheleſs, the Moors muſt be regarded as the chief poſſeſſors of Spain, until the middle of the 13th century. Their government in Spain was conducted by governors deputed by the caliphs, until the year 756, when Abdoulrahman ſeized the ſceptre of Spain, and became the Mooriſh king of Cordova. This dynaſty, under which Spain extended its commerce, and acquired very conſiderable wealth and power, continued until the year 1098, when the caliphate expired, and the Mooriſh governors of ſeveral provinces uſurped the royal ſtyle, in Cordova, Seville, Valencia, and Granada, and rivalled the ſmall Chriſtian kingdoms, till the middle of the 13th century, when the latter became predominant, and Spain reſumed her ſituation among the ſtates of Chriſtendom. The laſt of the Mooriſh royalties which was ſubdued, was the kingdom of Granada; and the crowns of Caſtile and Aragon were united in the perſons of Iſabella and Ferdinand V. A.D. 1474. Charles V. emperor of Germany, having married the heireſs of Aragon and Caſtile, eſtabliſhed the Spaniſh monarchy on its preſent baſis, A.D. 1516; and in conſequence of the acceſſion of American wealth, the power of Spain arrived at its zenith. In 1580 Portugal was added to Spain by Philip II., the ſon of Charles V.; but it revolted under Philip IV. A.D. 1640, and became a ſeparate kingdom. The Auſtrian dynaſty terminated at the death of Charles II., who died without iſſue, A.D. 1700; and this event was ſucceeded by the acceſſion of Philip V. of the houſe of Bourbon.

From the preceding abſtract of the principal epochs of Spain, it appears that this kingdom aroſe from the union of the provinces of the two crowns of Aragon and Caſtile; the number being four for that of Aragon, and twenty-two for Caſtile, without including the lordſhip of Biſcay and Navarre. The provinces of the crown of Aragon conſiſt of the kingdom of that name, the kingdom of Valencia, the principality of Catalonia, and the kingdom of Majorca:

thoſe of the crown of Caſtile conſiſt of the kingdom of Galicia, the provinces of Burgos, Leon, Zamora, Salamanca, Eſtremadura, Palencia, Valladolid, Segovia, Avila, Toro, La Mancha, Murcia, Guadalaxara, Cuença, Jaen, Granada, and Seville. Although this diviſion of Spain is the moſt ancient, and ſerves as the baſis for the impoſition and levying of the taxes, for the municipal laws, and the nature of privileges, the modern diviſion of Spain, with reſpect to the adminiſtration, is limited to thirteen provinces, kingdoms, or lordſhips, all of which have a captain-general, except Navarre, the intendant of which has the title of viceroy.

The *population* of Spain conſiſted originally of Celts from Gaul, and of Moors from Africa; the latter of whom, being more warlike, expelled the former. Towards the eaſt, it received large colonies of Carthaginians, and afterwards of Romans. In the fifth century it was conquered by the Vandals, and next by the Viſigoths, from whom ſeveral ancient families pretend even now to deduce their origin. The Mahometan Moors were ſo totally expelled, that they may be conſidered as almoſt extinct; and few families of Arabian extract now remain. We may, therefore, regard the modern Spaniards as deſcended from the African Iberians, the Celtiberian or German Gauls, the Romans, and the Viſigoths. The population of this country has varied much at different periods. In the time of Julius Cæſar it has been ſaid, that it contained at one period 40,000,000 of people, and at another period 52,000,000. This eſtimate, though apparently exaggerated, derives ſome degree of probability from the conſideration of the numerous armies which Spain furniſhed for a ſeries of years, during the Punic wars, in the time of the Romans and Carthaginians. The population of the towns ſeems to give us a very high idea of that part of the country in which they were ſituated. Merida afforded a garriſon of 80,000 infantry and 10,000 cavalry; and at the ſame period, the population of Tarragona amounted to about 2,500,000 inhabitants. The population of Spain ſuſtained but little diminution under the dominion of the Goths; but it very ſenſibly decreaſed during the Mooriſh dynaſty, on account of the multitude of victims that fell a ſacrifice to the ſanguinary ſword of the conquerors, and of thoſe who voluntarily exiled themſelves, in order to avoid oppreſſion. Spain, however, was again repeopled by the Chriſtians, who retook from the Moors the lands which they had rapaciouſly ſeized. Navarre, which formed a ſeparate ſtate, contained about 800,000 inhabitants; and near the ſame period, the ſtates dependent upon the crown of Aragon, which conſtituted the kingdom of that name, with thoſe of Valencia and Catalonia, furniſhed a very powerful army; and the town of Tarragona alone contained 80,000 families, or 350,000 inhabitants. The kingdom of Granada, ſubjugated by the Moors, had, at the ſame era, a numerous population. The city of Granada comprehended 70,000 houſes, occupied by 250,000 perſons, and furniſhed 50,000 ſoldiers. The kingdom, of which it was the capital, reckoned the number of its inhabitants at 3,000,000, on an extent of territory 70 leagues long by 30 in breadth. After the union of the different parts of the Spaniſh monarchy, in the reign of Ferdinand V. and Iſabella, its population is ſaid to have been 20,000,000; but as this eſtimate is exaggerated, it ſhould be reduced at leaſt one-third. In the year 1688 it amounted to no more than 12,000,000; and on the death of Charles II. and acceſſion of Philip V., in the year 1700, its numbers were reduced to 8,000,000. During the civil wars, which deſolated Spain in the firſt 13 or 14 years of that monarch's reign, it ſuffered a ſtill greater diminution, ſo that the population of the whole kingdom could not then have exceeded 6,000,000. Under the pacific reigns of the princes of the Bourbon family, the number of people in Spain greatly increaſed. The enumeration made by royal mandates, in the years 1767 and 1768, reported the population at 9,307,804 perſons; and by a new cenſus, taken in 1788 and 1789, by order of the king, the returns preſented 10,061,478. The lateſt eſtimate, formed in the year 1797, contains a much higher number, and is ſaid to have exceeded 12,000,000.

The ſtate of the Spaniſh population, in the year 1788, is exhibited in the following table.

According

SPAIN.

According to a ſtatement publiſhed at Madrid in 1802, the whole population of Spain appears to be 10,409,879; and thoſe who conſtitute the different claſſes as as follow:

Men	5,204,187
Women	5,205,692
	10,409,879

Out of this number, the calculation gives

Of ſingle men, religious, and widowers	3,257,022
Of nuns, widows, &c.	3,262,196
Total	6,519,218
Married perſons	3,890,661

As to the proportion between the extent of territory and the number of inhabitants, no eſtimate ſufficiently accurate has ever been made in Spain. For want of a more exact eſtimate, we ſhall here ſubjoin that of Haſſel, publiſhed at Brunſwick, in the "Statiſtique Européenne," which is ſuppoſed to be pretty accurate. According to this, Spain contains 25,145 ſquare leagues, of 25 to a degree, and 10,730,000 inhabitants, which will allow 425 inhabitants for every ſquare league. It will hence be eaſy to aſcertain the other numbers, by calculating after the proportion of 9 to 25. The equatorial degree is 25 French leagues, and 15 German miles; then reckoning their ſurfaces as the ſquares of their ſides, 9 ſquare German miles are equal to 25 ſquare leagues of France.

	Square German miles.	Inhabitants in general.	Inhabitants by ſquare Miles.
The whole of Spain	9053	10,730,000	1185
Kingdom of Caſtile	6628	7,278,000	1098
Provinces of Madrid, Toledo, Guadalaxara, Cuença, and La Mancha	1731	1,162,000	602
Burgos, Segovia, Soria, and Avila	740	915,000	1236
Leon, Valencia, Toro, Zamora, Valladolid, and Salamanca	805	939,000	1042

Lordſhip of Biſcay, compriſing Alava, Guipuzcoa, and Biſcay	280	300,000	1071

Others have ſtated the population of Spain at 11,000,000, and allow 74 perſons to a ſquare mile. Of its ancient population, numerous veſtiges exiſt in various parts of the country. And among the cauſes of its depopulation we may reckon the contagious fevers frequent in the ſouthern provinces, inceſſant inteſtine wars, the emigrations to America, the invaſion of the country by the Moors, the want of encouragement to agriculture, the multitude of detached farms, the effect of the *meſta*, (which ſee,) or wandering flocks, the number of unmarried clergy and monks, and, more eſpecially, that fanatic and miſtaken zeal, which proſcribed, on account of their religious tenets, two claſſes of wealthy and induſtrious people, the Jews and the Moors. Theſe were peculiarly valuable, on account of their intimate acquaintance with agriculture, arts, trade, and commerce. An edict iſſued at Granada, March 30, 1492, againſt the advice of the miniſtry, and many members of the ſupreme council, ordained, that every Jew who did not profeſs Chriſtianity within ſix months, ſhould be conſtrained to quit all countries under the government of the Catholic kings. Another equally impolitic edict was publiſhed in the year 1614, by which numbers of Moors, who, after having been ſubdued, had remained peaceably in Spain, were expelled the country. About 100,000 Jewiſh families pretended to be converted, and in the iſſue became victims to the inquiſition. More than 800,000 Jews left the kingdom, and migrated to France, Italy, Africa, and the Levant, and carried with them the wealth and other ſpecies of property which they had acquired by induſtry and trade. All the Moors, to the amount of 2,000,000, departed, leaving their towns and villages deſerted. We might add, as another collateral cauſe of the depopulation of Spain, the depredatory cruiſing of the Barbary pirates, for the ſpace of 300 years, by which they made numerous captives, both at ſea and by incurſions on the coaſts.

Towards the end of the 8th, and commencement of the 9th century, Spain was inhabited by four principal nations; *viz.* the natives, then known by the name of Romans; the Goths, comprehending the remains of the Suevi, Alani, and Vandals, ſeveral of whom were confounded with the natives and Moors, though a conſiderable part had taken refuge in the Aſturias and Navarre; the Moors, with whom the natives of Africa were mingled; and the French, who occupied a great part of Catalonia, Navarre, and the Pyrenees. Each of theſe nations brought with it its own genius, manners, laws, and cuſtoms; and beſides, the expulſion of the Moors from Spain was ſucceeded by the formation of ſeveral independent ſovereignties, each of which had its own laws and particular form of government. Hence reſulted a diverſity of genius, temper, manners and cuſtoms; which, though in ſome degree modified by the preſent uniformity of government, ſtill ſubſiſts; ſo that there are no two provinces exactly reſembling each other in manners and character. Some cuſtoms, however, and ſome traits of character, correſpond to one another in all the provinces. The national pride is every where the ſame, and this the Spaniard energetically expreſſes by his geſtures, words, and actions. In many caſes this is the pride of virtue, or a natural dignity of ſentiment, which ſoars above vice and folly. With this pride, which is diſcernible in all ranks of life, and in all claſſes of ſociety, the Spaniards combine, in a very eminent degree, temperance and valour. Of their valour in more remote ages, Thucydides, Diodorus Siculus, Livy, Strabo, and Lucius Florus, furniſh a variety of inſtances; nor have they altogether loſt this diſtinguiſhing quality of their anceſtors. In this reſpect, ſome ſhades of difference have been obſerved among the military of different provinces. The Galicians are accounted the beſt ſoldiers in Spain. Strabo has ſaid of them, that they were warlike, and that it was difficult to ſubjugate them. The valour of the Catalonian is ſaid to be the moſt intrepid; that of the Aragoneſe the moſt conſiderate; that of the Andaluſian the moſt preſumptuous; that of the Caſtilian the cooleſt; and that of the Biſcayan more active amongſt rocks than on the plain. The Spaniards are reckoned to be, in general, very grave and reſerved; and in their addreſs, cold and repulſive; but blended with their gravity, they manifeſt a degree of gaiety, particularly ſince the acceſſion of the houſe of Bourbon, which is frank and lively. Notwithſtanding this occaſional vivacity, the Spaniard is very tardy and ſlow in all his operations, reſpecting not only buſineſs and politics, arts and ſciences, but even their amours and pleaſures. That indolence and hatred of labour which prevail in their national character, have produced an averſion for agriculture and commerce, the effects of which have been nationally injurious. It has been obſerved, however, that this kind of apathy and indiſpoſition to labour, ſolely, or principally, prevail in thoſe parts where induſtry is without a ſpur, activity without an object, and commodities without a vent. The provinces near the ſea are all induſtrious; the inland provinces, deſtitute of canals and navigable rivers, and, till of late, of roads, and poſſeſſing no cheap or eaſy mode of communication, have no means of ſupporting induſtry.

The Spaniards were formerly very jealous of their wives and miſtreſſes; the women were ſhut up in their own houſes as in a kind of priſon, where thick lattices concealed them from the obſervation of impertinent curioſity. They received few viſits in the apartments to which they were confined, and which no man could enter without great difficulty and many precautions. They were placed under the guardianſhip of one or more duennas, and could not take a ſingle ſtep, either in their own houſes or abroad, which was not ſubject to their inſpection. Whenever they went out, a veil concealed the face from every paſſenger.

Times are greatly altered; huſbands are now much leſs ſuſpicious—more reaſonable, or more eaſy—and women much more acceſſible. Lattices and jealouſy have diſappeared; duennas only exiſt in romances; veils, under the name of *mantelas*, have become an ornament which gives effect to beauty; all houſes are thrown open; the men, gallant and amorous as ever, are become leſs captious; the women have recovered a liberty by which they are, perhaps, leſs tempted to go aſtray than formerly, when their virtue was entruſted to locks and grates, and to a ſuperintendance often faithleſs, and eaſy to be corrupted.

Both the men and women have gained by the change; the former have become leſs moroſe, more frank and agreeable; the women more attractively diſcloſe the many eaſy graces with which they were endowed by nature.

Several of the games, diverſions, and public ſpectacles of the Spaniards, are derived from the Moors, and to the ſame origin we may trace many of their cuſtoms, and even that kind of dreſs and mode of living which were long prevalent in this country. After the expulſion of the Moors, the Goths and native Spaniards, blended together and forming one nation, adopted the ſame coſtume and manners. On the acceſſion of Philip V. the Spaniſh habit was neglected and diſuſed, and the French, which ſtill prevails, ſubſtituted for it. The Spaniards are now as luxurious in their dreſs as they were formerly ſimple; they make uſe of the richeſt ſtuffs and ſilks, as well as of embroidery in ſilk, gold, and ſilver. The moſt varied and conſpicuous colours have ſucceeded to black, which was, for ſeveral centuries, the national coſtume. The common people, however, in ſeveral of the provinces, retain their ancient mode of clothing, with ſome diverſity in different parts of the country. Different profeſſions have their peculiar coſtume in Spain. Uniforms are very numerous, and are not confined to the military. The Spaniſh nobility have an uniform for the holy week; they wear it at court and in town, and the king and royal family wear the ſame. The coat is of black velvet, lined with crimſon ſatin, with gold, or gold embroidered buttons, and facings of gold brocade on a crimſon ground, or of ſatin of the ſame colour embroidered with gold. The waiſtcoat is the ſame as the facings, and the breeches are black. This dreſs is handſome and dignified. Among the amuſements of the Spaniards we may reckon the feſtivals of the church, which in ſeveral of the provinces, particularly in Aragon, are attended with very brilliant and magnificent decorations; the fire-works, which are very common in Spain; the maſquerades, which were formerly much in faſhion in Spain during the carnival, particularly in Aragon; and the bull-fights, which were the true national ſpectacle; but this amuſement was ſuppreſſed ſeveral years ago. The amuſements of people of rank chiefly conſiſt in dancing and cards; and the theatre is much frequented, though the plays and muſic do not correſpond in excellence with the national refinement.

The origin of nobility in Spain cannot be preciſely aſcertained. Of this order of perſons no traces appear, whilſt the country continued under the dominion firſt of the Carthaginians, and afterwards of the Romans. The rudiments of it firſt manifeſted themſelves under the Gothic kings; but it was almoſt totally annihilated by the Saracenic invaſion. After the expulſion of the Moors, a regular order of nobility began to grow up in the newly eſtabliſhed kingdoms of Spain, with peculiar modifications in different ſtates. The only method of acquiring nobility in this country is by a royal grant, as it is not attached to the exerciſe of any office, civil or military: and the price of a patent of nobility varies in the different provinces. Of late years a diſtinction has been taking place, between the titled and untitled nobility. The former are ſo called becauſe they have obtained from the king the title of grandee, of duke, of count, of marquis, or of viſcount. Theſe titles of nobility are hereditary in the families of thoſe to whom they have been granted, and deſcend firſt to the males, according to ſeniority, and then to the females, who have a right to transfer them to their huſbands and to their children. The titled nobility, unleſs they have been advanced to the dignity of grandee, enjoy few privileges above thoſe that are entitled. The grandees, of whom there are ſeveral claſſes, are at the head of the Spaniſh nobility, and at court take precedence of all ſecular dignities, except thoſe of conſtable and admiral of Caſtile. The moſt valued privilege belonging to the grandees is that of being covered in the royal preſence. The number of titled nobility in the year 1787 was as follows; 129 grandees, 535 marquiſes, counts, and viſcounts; of theſe latter, 142 habitually reſided at court, and the reſt in the provinces.

The military orders in Spain were formerly eleven, all of which are become extinct. At preſent there are ſeven different orders, *viz.* thoſe of the Golden Fleece, of San Jago, or St. James of the Sword, of Calatrava, of Alcantara, of Monteſa, of Charles III., and of Maria Louiſa. Of theſe, the firſt has paſſed by ſucceſſion to the Spaniſh crown, the four next are the military orders properly ſo called, and the two laſt are of modern inſtitution. (See GOLDEN *Fleece*, *St.* JAMES *of the Sword*, CALATRAVA, ALCANTARA, *St.* GEORGE *of Alfama.*) For the four laſt named military orders the qualifications at preſent neceſſary are eight years of active ſervice in the Spaniſh army, and proofs of nobility of four degrees, on the ſide of both father and mother. The only advantage that accrues of neceſſity, on admiſſion into any of theſe four orders, is the honour of wearing the croſs, beſides a few unimportant privileges: the commanderies are places of pecuniary profit, belonging to thoſe who have taken the vow of combating the infidels, of fidelity towards the ſovereign, and of conjugal charity. The order of Calatrava has 20 of theſe, valued at 71,250*l.* ſterling; that of San Jago has 87, valued at 81,250*l.*; that of Alcantara has 37, worth 39,000*l.*; and that of Monteſa 13, at 12,588*l.* To each of the orders belong monks, and ſeveral convents of nuns. The order of Charles III. was founded by the king of that name, on the 19th of September, 1771, and placed under the immediate protection of the Holy Virgin, under the title of the Conception. Of this order the ſovereign is chief; he alone nominates the grand croſſes and knights. The order is compoſed of ſixty grand croſſes, two hundred penſioned knights, and an indefinite number of others; of a grand chancellor and miniſter, who is always the patriarch of the Indies; of a ſecretary, a maſter of the ceremonies, and a treaſurer.

The croſs of this order is of eight points, ſurmounted by a royal crown, with a figure of the conception in the middle; it is worn hung to a ribband of three equal ſtripes, the two outer of which are blue, and the inner white. The grand croſſes wear this ribband much broader than the knights, ſaltierwiſe from the right ſhoulder to beneath the left arm, with a conception of ſilver embroidery on the left ſide of the habit and cloak. On days of ceremony they wear a long cloak, and a collar, the links of which are formed alternately of the king's cypher and the arms of Caſtile. The knights wear the croſs hung from the button-hole by a narrow ribband. The penſions of the knights (of which there are 200) are each fixed at the ſum of 4000 reals: they are given to military men, to men of letters, to lawyers, to gentlemen, and to thoſe employed in the miniſterial departments. This order has a ſupreme council, compoſed of the ſovereign, of the grand chancellor of the order, who is alſo vice-preſident, of a ſecretary, a fiſcal, an accomptant, and ten counſellors.

The order of Maria Louiſa is very modern, having been eſtabliſhed in 1792, by Charles VI., who named it after the queen his wife. Only ladies are admitted into this order. The grand-maſterſhip is veſted in the queen, and the number of ladies is thirty. The croſs of the order is a medallion, with a portrait of the queen, hung to a violet ribband, divided in the middle by a white ſtripe, and worn ſaltierwiſe.

In Spain there is a deſcription of perſons denominated "Mayorazgos." The term, derived from the word *mayor*, or firſt-born, implies, ſtrictly ſpeaking, the right poſſeſſed by the eldeſt-born of a family, to inherit certain property, on the condition of tranſmitting it entire and undiminiſhed to thoſe who may be poſſeſſed of the ſame right on his deceaſe.

The import of this term has, however, been much extended by uſe; for, though it properly means only the right of ſucceſſion to a perpetually entailed eſtate, in virtue of primogeniture, yet it now ſignifies, in addition, the cauſe which produces the right, the property which is the object of it, the actual poſſeſſor of the property, and the perſon who ſtands next in ſucceſſion.

Of theſe mayorazgos there are five claſſes or kinds, diſtinguiſhed by certain circumſtances incident to the deſcent or transfer of property. Many diſadvantages have attended the extenſive multiplication of mayorazgos; eſpecially when the ſucceſſion deſcends to females. Inſtead of perpetuating families, for which purpoſe the inſtitution was intended, it very much contributes to their extinction; it injures the general progreſs of agriculture, and it encourages idleneſs, to which the Spaniards are very much addicted.

Literature, Sciences, the Arts, and Language.—The ſtate of ſcience in Spain, before the time of the Romans and Carthaginians, is wholly unknown; but when the Romans introduced with their arms the arts of civilization, the Spaniards began to cultivate literature and the ſciences, and produced ſeveral writers who attracted diſtinguiſhed notice: ſuch were L. A. Seneca, a native of Cordova; the geographer M. Pomponius Mela, of Andaluſia; and J. M. Columella, of Cadiz, whoſe works on agriculture and rural economy are even now held in high eſtimation. Under the Goths, when literature was reſtrained and oppreſſed, Spain furniſhed perſons no leſs diſtinguiſhed by their virtues than by their talents and writings. To this claſs we may refer Hoſius, biſhop of Cordova; Gregorius Boeticus, biſhop of Elvira; S. Ildefonſo, archbiſhop of his native place, Toledo; S. Iſidore, a native, and afterwards archbiſhop, of Seville; Priſcillianus of Galicia; Petrus of Saragoſſa, a diſtinguiſhed orator; Aurelius Prudentius, of Calahorra, an eſteemed poet; and Aquilius Severus, who wrote an account of his travels in Africa. The invaſion of the Moors introduced a period of barbariſm; but at this time we find, without mentioning perſons of leſs note, king Alphonſo IV. of Caſtile and X. of Leon, who was celebrated for his acquirements in various departments of literature and ſcience; who was a legiſlator, orator, hiſtorian, poet, mathematician, and aſtronomer; and who merited the appellation of "El Sabio," the ſage, which was conferred upon him by general conſent. Although the native Spaniards were plunged in ignorance, the Moors united with the moſt romantic bravery, a paſſionate love of ſcience and the arts. Beſides their theatres, public ſhows, and tournaments, they eſtabliſhed public ſchools in every town under their dominion, of which thoſe of Seville, Cordova, and Granada, obtained a high degree of reputation. They eſtabliſhed in various places colleges and academies, as well as libraries, for the promotion of ſcience and literature. The ſciences cultivated by them with eminent ſucceſs were, geography, experimental philoſophy, optics, botany, chemiſtry, medicine, natural hiſtory, geometry, and other branches of the mathematics. When the Moors were expelled, the fortunate and brilliant reign of the Catholic ſovereigns Ferdinand and Iſabella was the era in which knowledge revived, and its boundaries were enlarged during the reigns of Charles V. and Philip II. During the inauſpicious period that ſucceeded the reign of Philip II., ſeveral perſons of diſtinguiſhed genius and attainments exerted themſelves for the protection and encouragement of ſcience; and it would be tedious to mention even the names of thoſe who excelled in various branches of learning. We cannot, however, forbear mentioning Benedict Feyjoo, a Benedictine monk, who died at Oviedo in 1762, and who did honour to his country at a time when literature, ſcience, and the arts, were almoſt wholly neglected and unknown. To him Spain was indebted for the reſtoration of literature, good taſte, and the love of ſtudy. We might alſo enumerate among its diſtinguiſhed poets and hiſtorians, Quevedo, Cervantes, Saavedra, Lopez de Vega, Guevara, Mariana, Granada, Solis, Herrera, &c.

The number of univerſities, or rather academies, in Spain, was formerly twenty-four, but the following ſeventeen are all which now remain, *viz.* that of Pampeluna, in Navarre; of Oviedo, in the Aſturias; of San Jago, in Galicia; of Seville, and of Granada, in the provinces of the ſame name; of Hueſca and Saragoſſa, in Aragon; of Avila, Oſma, and Valladolid, in Old Caſtile; of Toledo, Siguenza, and Alcala de Hamarez, in New Caſtile; of Cervera, in Catalonia;

lonia; of Orihuela and Valencia, in Valencia; and of Salamanca, in the province of Leon. Several of theſe ſcarcely deſerve notice. Thoſe of Saragoſſa, Alcala, and Cervera, retain ſome degree of importance; but the moſt ancient and moſt celebrated is that of Salamanca; for an account of which ſee that article. The moſt popular univerſity at preſent is ſaid to be that of Valencia. The conventual ſchools are numerous; and Spain has four military ſchools, *viz.* at Barcelona, Zamora, Cadiz, and Segovia. Public libraries are alſo numerous.

The native tongue of the ancient Spaniards was utterly loſt during the domination of the Romans, whoſe language in the corrupt form of the middle ages became that of Spain. The Goths brought into the country their own Teutonic dialect; and as the natives continued to ſpeak Latin, their language became at length a mixture of Latin and Teutonic. The Arabs, in their turn, introduced the ſpeech of their country, veſtiges of which remained after their expulſion. Hence it appears, that the Spaniſh language was compounded from three different ſources: the Latin prevailed over the other two, and the Gothic ſtill preponderates over the Mooriſh. Within the laſt two or three centuries the Spaniſh language has undergone conſiderable alterations; it ſtill, however, preſerves the ſame roots, the ſame turn of phraſe, and the greater number of its words, but altered in their inflections and terminations. The Spaniards themſelves boaſt, among other excellencies, of the facility with which it is pronounced; it is ſounded, they ſay, exactly as it is written, but this aſſertion is too general In ſome reſpects this language is very rich; it abounds in compound words, in ſuperlatives, derivatives, augmentatives, diminutives, and frequentative verbs; it has many quite ſynonimous words, and others which well expreſs the different ſhades of meaning. In the technical terms of arts and ſciences, it is, however, extremely poor; a few of theſe it has borrowed from the Latin, and almoſt all the reſt from the French.

On the whole, the Spaniſh is one of the fineſt of the European languages. It is dignified, harmonious, energetic, and expreſſive; and abounds in grand and ſonorous expreſſions, which unite into meaſured periods, whoſe cadence is very agreeable to the ear. It is a language well adapted to poetry, but it alſo inclines to exaggeration, and its vehemence eaſily degenerates into bombaſt. Though naturally grave, it eaſily admits of pleaſantry. In the mouth of well educated men it is noble and expreſſive; lively and pointed in that of the common people; ſweet, ſeductive, and perſuaſive when uttered by a female. Amongſt the orators it is touching and impoſing, though rather diffuſe; at the bar and in the ſchools it is barbarous; and is ſpoken by thoſe about the court in a conciſe and agreeable manner.

The Spaniards articulate ſtrongly, and ſometimes with a kind of guttural ſound, which greatly impairs the grace and dignity of their ſpeech, but the pronunciation differs materially in different provinces. In Catalonia it is harſh and conſtrained; harſh alſo and dry in Aragon; quick and lively in Biſcay; agreeably modified in the kingdom of Valencia; boaſtful and mouthing in Andaluſia; ſofter, ſweeter, and more natural in Caſtile.

The Spaniſh language is not ſpoken with the ſame purity in all parts of the kingdom. Beſides the old provincial dialects, which ſtill prevail in many parts, the Baſque is ſtill ſpoken in Biſcay; and the language is mixed with French in Navarre, with Portugueſe in Galicia, and with Arabic in Murcia and Andaluſia. It is in New Caſtile, and eſpecially in the ancient kingdom of Toledo, that it is beſt ſpoken; and there that a ſtranger ought to learn it who deſires to become acquainted with all its delicacies and beauties. The ancient Limouſine or Provençale forms the baſis of the dialects of Catalonia and Valencia.

Baſque is ſpoken in the lordſhip of Biſcay, in Guipuſcoa, and in the greateſt part of Alava. This language is very ancient; it differs entirely from the Spaniſh, either ancient or modern; it exiſted before the arrival of the Romans, and was then unlike what was ſpoken in the other parts of Spain; it is mentioned by Strabo, Seneca, and Pomponius Mela. It has been preſerved to our days almoſt without alteration or corruption, particularly in the more mountainous parts. It is very difficult to ſtrangers, and appears to thoſe who do not underſtand it a coarſe and barbarous tongue, deſtitute of elegance and expreſſion; but ſuch as are verſed in it account it very ſweet and expreſſive.

The Spaniards, abhorring the Moors, diſdained to apply themſelves to the arts which they exerciſed; and hence proceeded a general contempt for artiſans, which has been perpetuated to the preſent time, and has greatly retarded their progreſs in Spain. The arts which are employed in manufactures are much advanced in Spain. The 16th century was the moſt brilliant period of the arts in Spain, as well as of the ſciences, of literature, and of the power and grandeur of the monarchy. Many able architects appeared at once under Charles V. and Philip II., who erected numerous edifices, that will immortalize the reigns of thoſe princes and the names of the artiſts, ſuch as John de Herrera, Cepedes, Pedro de Uria, and John Baptiſt Monegro of Toledo, the latter of whom aſſiſted in the building of the Eſcurial, and of the church of St. Peter at Rome. The ſtructures of this age are the fineſt in Spain. Architecture, however, very much declined in the 17th century; but about half a century ago it began again to be cultivated with ſucceſs. Spain juſtly boaſts of a number of ſculptors of diſtinguiſhed merit, among whom we might mention Paul Cepedes of Cordova, and Alonzo Cano of Granada. Of all the liberal arts, painting is that which has been moſt cultivated in Spain; and though the Spaniſh ſchool is little known, it deſerves notice, as occupying a middle place between the Italian and Flemiſh ſchools, being more natural than the firſt, more noble than the ſecond, and participating the beauties of both. It has particularly excelled in ſacred ſubjects. Moſt of the painters of Spain are of the 17th or the end of the 16th century. In the 18th century painting was almoſt totally annihilated in Spain; but the Spaniſh ſchool was recovered about the middle of the ſame century by Antonio Raphael Mengs. Spain now poſſeſſes an academy of painting at Seville, and two academies of the fine arts, one at Madrid, and the other at Valencia; and public, gratuitous ſchools for drawing have not long ago been eſtabliſhed in various places. The Spaniards have a taſte for muſic, and have cultivated it with ſucceſs. They prefer the Italian to the French muſic, the latter being in their opinion too languid and monotonous. The Moors were the firſt in Spain who cultivated muſic ſcientifically, and who eſtabliſhed ſchools for teaching it: and the Spaniards have been led to imitate them. The Mooriſh muſic conſiſted chiefly of ſoft and tender airs, ſung by one or more voices, and accompanied by the lute: and the modern Spaniards have alſo their national muſic, reſembling that of the Moors, and confined to detached airs, which are ſung by one or more voices, and accompanied by the guitar. Spain has alſo adopted the muſical inſtruments generally uſed among other nations, and it has ſome that are peculiarly its own. Different provinces have their appropriate inſtruments. For the hiſtory of Spaniſh muſic, ſee the ſequel.

We have already mentioned dancing as one of the amuſements to which the Spaniards are much addicted. Beſides thoſe dances which are provincial, they have three which are national; *viz.* the fandango, the bolero, and the ſequidilla. The fandango is very ancient; it is probably referred to by Martial, and it is defined by Baretti to be a regular and harmonious convulſion of all parts of the body. The bolero, which is quite modern, is an imitation of the former, but ſhortened and modified, and ſtripped of all thoſe acceſſaries, which give to the fandango ſo very free a character. The ſequidilla is an imitation of the ſteps of the two others formed into a ballet. Theſe dances are uſually performed to the ſound of the guitar, accompanied by the voice of the player. The women very correctly mark the time with the heel, a motion which adds a new grace.

Climate, Soil, and Agriculture.—The climate of Spain is equal, if not ſuperior, to that of any country in Europe; it is in general very dry, and irrigation is rendered difficult by the chains of mountains that interſect it. The climate is various in different provinces, and in thoſe that lie to the ſouth the heat is inſalubrious, and ſometimes occaſions epidemic diſeaſes that are very fatal. Theſe are partly owing to ſtagnant and undrained marſhes, and to the neglect of proper culture. The chains of mountains that interſect the country at various diſtances from E. to W. ſerve to temper the climate, and ſupply cooling breezes. In the ſouth the ſea-breeze, commencing about nine in the morning, and continuing till five in the afternoon, moderates the heat of ſummer: and the ſeverity of winter in the northern provinces is allayed by the gales of the ocean, at no great diſtance. It has been obſerved, that the temperature of Spain is influenced by its peculiar configuration, and by the ſingular height of this country above the level of the ſea, inſomuch, that although from the N.E. it gradually becomes lower, yet the high plain, or table land of the Caſtiles, has an elevation of upwards of 300 fathoms. According to the obſervations of Humboldt, the interior of Spain is an elevated plain, and the higheſt of any of the ſame kind in Europe, which occupies a large extent of country. The mean height of the barometer at Madrid, obſerved by Don Felipe Bauza, ſhews that capital to be elevated at 309⅗ fathoms above the level of the ocean, allowing the barometer on the coaſts to be at 338 and 24 lines. Hence it appears that the elevation of Madrid is 15 times greater than that of Paris, three times greater than that of mount Valerian, and alſo three times greater than that of Geneva, which is 188 fathoms above the level of the ſea. This height of the plain of the Caſtiles has an obvious effect upon its temperature. The mean temperature of Madrid appears to be 59° of Fahrenheit, while that of Peterſburgh is 39° 52′ 30″; that of Berlin, 46° 57′ 30″; that of Paris, 53° 56′ 15″; that of Marſeilles, 58° 33′; that of Toulon, 61° 15′; that of Naples, 63° 30′; and that of the countries ſituated under the equator and on the level of the ocean, from 79° to 81°. Genoa is four degrees more to the north than Madrid, and yet the temperature of Genoa raiſes the glaſs almoſt two degrees higher than that of the capital of Spain. Such is the influence of local cauſes, of the elevation of ſcite, the proximity to the ſea, a chain of mountains which keeps off the cold northerly winds, and a great number of little circumſtances, the combination of which moderates the temperature of places.

If the mean temperature of the elevated plains of Spain is 59° of Fahrenheit, that of the coaſts from the 41ſt degree of latitude to the 36th, is between 63½° and 68° Fahrenheit. Thus we ſee banana-trees, heliconias, and ſugar-canes, growing upon theſe coaſts in ſituations that are ſheltered from the cold winds.

Upon the whole, the face of the country is in moſt ſeaſons delightful, abounding with excellent and fruitful paſturage, vineyards, and groves of orange-trees; and the hills ſtocked with wild thyme and other odoriferous plants. The rivers and ſtreams are numerous; and the chains of mountains afford a great variety to the proſpect. The moſt northern of theſe chains is regarded as a continuation of the Pyrenees, paſſing on the S. of Biſcay and the Aſturias into Galicia; and it is variouſly denominated, as the mountains of Biſcay, the Sierra of Aſturias, and the mountains of Mondonedo in Galicia. It is alſo known by the names of the mountains of Santiliana, of Vindo, and of the mountains of Oea. We here obſerve that the term "Sierra," peculiar to Spain, denotes a chain of mountains, the ſucceſſive peaks of which preſent the reſemblance of a *ſaw*. The gypſeous and argillaceous mountains of this country rarely exhibiting any ſupreme elevation, like thoſe in the granitic chains, naturally ſuggeſted this appellation. The ſecond chain of Spaniſh mountains extends from near Soria on the N.E., and purſues a S.W. direction towards Portugal. This chain is called that of Urbia, or Guadarama, and alſo the Montes Carpentanos. The third is that of Toledo, or Guadalupe, running nearly parallel with the laſt. Theſe two central chains ſeem to contain great quantities of granite. Next towards the S. is the Sierra Morena, or brown mountains, which are followed by the moſt ſouthern ridge, that of the Sierra Nevada. On the E. there is a conſiderable chain, which connects the two central ridges, and advances towards the Mediterranean in the N. of Valencia. There are alſo conſiderable ranges of hills in this part of the kingdom, generally running from N. to S. Near Barcelona is a remarkable ſolitary mountain, at a diſtance appearing like a ſugar-loaf, and on a nearer approach jagged like a ſaw, with pyramidal rocks; compoſed of ſarcilite or pudding-ſtone, formed of limeſtone gravel united by calcareous cement; and ſo high, that from its ſummit may be ſeen the iſlands of Majorca and Minorca, at the diſtance of 50 leagues. The circumjacent region conſiſts of argillaceous ſchiſtus, with clay and ſand. Not far from this mountain, called Montſerrat, near the village of Cardona, is a hill three miles in circumference, which is a maſs of rock-ſalt, uſed in the dry climate of Spain for vaſes, ſnuff-boxes, and trinkets, like our Derbyſhire ſpar.

According to the deſcription of the ingenious obſerver, Mr. Townſend, the northern ſide of the Pyrenees (which ſee) is chiefly calcareous, ſurmounted with argillaceous ſchiſtus; but the ſouthern is granite, and of courſe barren. The hills to the S. of Gerona are alſo granitic. The higheſt ridge in Spain, near Daroca, from which originate the Tajo and the Ebro, ſeems to be compoſed of argillaceous ſchiſtus, and free-ſtone, probably reſting on granite. Near Anchuala the mountains are limeſtone with ſhells, and in ſome places contain beds of red gypſum, with cryſtals of the ſame colour. In general, gypſum is as abundant in Spain as chalk is in England; and the gypſum produces cryſtals of ſea-ſalt and Epſom ſalt, and abundance of nitre. The mountains on the N. of Madrid, forming part of the central chain, are granite. Thoſe to the N. of Leon are chiefly marble or limeſtone, on a baſis of argillaceous ſchiſtus, riſing in bold and rugged rocks, which afforded a barrier to the remains of Spaniſh liberty. In returning towards the S. the ſoil of La Mancha is ſandy, the rock gypſum. The higher regions of the Sierra Morena are granite: the lower, argillaceous ſchiſtus with gypſum and limeſtone. The granite is of two kinds, the red and the white. Near Cordova the higheſt hills are

are covered with rounded maſſes of granite, grit, and limeſtone. Near Malaga are branches of the Sierra Nevada, or ſnowy chain, an appellation which might be extended to the central range between Old and New Caſtile, which, according to Mr. Townſend, may at ſome times be viſible at the diſtance of 100 miles: theſe branches preſent limeſtone and marble, ſurmounted by argillaceous ſchiſtus. Near Alhama, S.E. of the city of Granada, are found rocks, which, on a baſis of ſhingle or round gravel, preſent ſand-ſtone with ſhells, ſurmounted with ſarcilite; but in general the rocks are gypſeous, with ſtrata of the ſame ſubſtance cryſtallized. Mr. Townſend ſuppoſes that the power of the ſun contributes to impregnate chalk with vitriolic acid, thus forming gypſum. The S.E. part of Spain ſeems to be equally calcareous, and the cathedral of Murcia is built with piſolite, a ſort of free-ſtone, reſembling the roe of fiſh. The aventurine is found in the mountain of Gata, towards the frontiers of Portugal; the Cape de Gata preſents alſo ſome ſingularities, and appears to ſome travellers to have been volcanic.

The foreſts, or rather chaces of Spain, are numerous. They are little cultivated, and are partly reſerved for the pleaſures of hunting; ſuch is that of the Pardo, which is barren of trees, and extends about 30 miles. Some of the foreſts are haunted by ſmugglers and banditti, who rob travellers, and often commit murders.

Spain, including the whole country S. of the Pyrenees, in relation to botany, and its vegetable productions, has been divided into the ſea-ſhore, the high mountains, the lower ones, the arable lands, the grazing tracts and marſhes along the rivers, and the vicinity of Liſbon and Oporto. The ſea-ſhore, with reſpect to its vegetables, reſembles for the moſt part the northern coaſts of the Mediterranean; the flat ſandy tracts being occupied by the ſea-daffodil, the ſhrubby glaſs-wort, and the ſalſola ſoda and ſativa; and of the latter there are extenſive plantations in the vicinity of Alicant and Barcelona, the aſhes of which yield the barilla, of which ſome thouſand tons are annually manufactured: the rocks on the coaſt are chiefly calcareous, and abound with ſeveral vegetables, and particularly with the ſtipa tenaciſſima, or eſparto graſs, uſed in making ropes, mats, chair-bottoms, &c. The high mountains of Spain are covered with ſnow only for a few weeks in the year, and in theſe elevated regions are found the fineſt timber trees, and other vegetable productions of the ſame kind with thoſe that are met with in the north of Europe. The long ranges of hills that occupy the greateſt part of Spain, conſiſt either of extenſive arid tracts of ſand, arenaceous ſand-ſtone, and ferruginous rubble forming the heaths, of dry calcareous diſtricts forming the ſheep-walks, or of moiſt rough granitic and marble ridges, with a ſhallow ſoil, forming the woodlands. The Spaniſh heaths are gayer and richer with plants than thoſe of any other European country. The ſheep-walks are for the moſt part open downs, with little ſhelter, excepting occaſionally groves of cheſnut-trees or evergreen oaks. In the wood-lands the trees are neither ſo large nor ſo ample in their foliage as thoſe of the German and Engliſh foreſts. The maritime provinces of Spain abound with wood; but in the interior provinces trees are rare, and plantations are not ſufficiently encouraged. Portugal and Spain are deficient in reſpect of water; the rivers flow through rocky channels, and therefore the marſhes and bogs are infrequent. The vicinity of Liſbon and Oporto, and of a few other towns on the coaſt, afford a number of Indian, African, and American plants.

In zoology, Spain is celebrated for its horſes and mules, the latter however being more regarded than the former, which are ſaid to degenerate, and particularly for its ſheep, which are ſuperior to thoſe of other countries with reſpect to the delicacy of the mutton and the beauty of the fleece.

In mineralogy, Spain was formerly more diſtinguiſhed than it has been in later times. Pliny, Strabo, and Polybius, ſpeak in high terms of commendation of its precious metals; ſo that Britain and other maritime regions received their gold and ſilver from Gaul and Spain, in return for cattle, hides, and other products. At preſent the ſilver-mines are almoſt wholly confined to Guadalcanal in the Sierra Morena, though rich veins of the ſame metal, in a fuliginous ſtate, exiſt in many places. The quickſilver mines of Almadan in La Mancha furniſh America with mercury for refining its more precious metals. Calamine, cobalt, antimony, copper, tin, and lead, are found in Spain; its iron is valuable; and coals are obtained in the diſtrict of Villa Franca, in Catalonia, where alſo occur gold, ſilver, copper, and lead. Amber and jet are found in the territory of Betonica, in the Aſturias. The other minerals it is needleſs to enumerate. Murcia produces a fine red earth, called "almagra," which is mingled with the Spaniſh ſnuff. The aventurine of Spain is a felſpar ſprinkled with golden mica.

Few of the mineral waters of Spain are much celebrated. The hot ſprings near Oviedo reſemble thoſe of Bath; and thoſe near Alicant are warm ſprings of a chalybeate nature, riſing like the fumes among calcareous hills.

We ſhall now advert to the *agriculture* of Spain. The ſoil in Spain is generally light, and repoſes on beds of gypſum; nor is any country in Europe upon the whole ſo fertile as this, or poſſeſſing equal advantages at all ſeaſons of the year. It was, indeed, in this region that the ancients fixed the ſcite of the Elyſian fields, and the gardens of the Heſperides. When the Romans firſt entered Iberia, they were aſtoniſhed at the productive and flouriſhing ſtate in which many parts of it were found; and they encouraged the exiſting induſtry, ſo that Spain became the granary of their empire, and the nurſery of their armies. The northern nations, when they took poſſeſſion of the country, parcelled out the lands, and turned their attention to the improvement of agriculture. They conſtructed ſubterraneous buildings, or granaries, in uſe before their time, for the preſervation of corn, and encouraged the formation of canals and ſluices, for the irrigation of the land. Under the Moors agriculture was in a ſtill more flouriſhing ſtate; and the era of their expulſion deſignates the epoch of the decline of agriculture. The Spaniards, deprived of their aſſiſtance, poſſeſſed neither talents, activity, nor perſevering induſtry, for the cultivation of their lands; and though they had an excellent ſoil, and numerous rivers to counteract its aridity, and nothing but induſtry and labour were wanting, ſcarcely two-thirds of the country were under cultivation: ſo that they have been under a neceſſity of importing a large quantity of corn from foreign countries. Many attempts were made by ſucceſſive Spaniſh monarchs to rouſe the ſpirit and invigorate the ſyſtem of agriculture; but they proved, from various impeding cauſes, in a great degree ineffectual. A variety of circumſtances contributes to diminiſh the number of perſons that are inclined to labour, as well as to contract the portion of time that may be employed for this purpoſe. Although Spain has a population of 10,143,965 perſons, yet of theſe, the women, children, and old and infirm men, conſtitute five-eighths of the whole, and reduce the population to about 3,803,981 men. From this number muſt be ſubtracted the ſecular and regular clergy, military and navy, nobility, ſtudents, counſellors, ſcriveners, domeſtics, and tax-gatherers, amounting to 1,221,799 perſons; ſo that the number of thoſe who might be actively employed in agriculture, ſubject to a ſtill further reduction, amounts to conſiderably leſs than 2,582,592. The number of working days is much leſſened by the multiplicity of feaſts and holidays. The want of good roads and of convenient markets, the high price of labour, and the "meſta" (which ſee), very much impede agricultural improvement. Under all theſe diſadvantages, ſo fertile is the ſoil and ſo favourable the climate, Spain produces a very conſiderable quantity of various ſorts of grain; but different provinces are more or leſs diſtinguiſhed in this reſpect. Flax, hemp, ſugar-canes, madder, ſoda, ſaffron, broom, honey, palms and dates, cork-trees, kermes or gall-inſects, and different kinds of fruit, almonds, nuts, figs, carob-beans, olives, vines and dried raiſins, may be reckoned amongſt its productions. The common courſe of huſbandry about Barcelona, as Mr. Townſend informs us, begins with wheat; which being ripe in June is immediately ſucceeded by Indian corn, hemp, millet, cabbage, kidney-beans, or lettuce. In the ſecond year theſe crops ſucceed one another as before. In the next year they ſow barley, beans, or vetches, which being taken off the ground before Midſummer, are followed, as in the former year, by other crops, changing them according to the ſeaſon, ſo as to have on the ſame ſpot the greateſt variety. Wheat produces a ten-fold crop, and in rainy ſeaſons fifteen for one. Near Carthagena, the courſe is wheat, barley, and fallow. For wheat they plough thrice, and ſow from the middle of November to the beginning of December; in July they reap from 10 to 100 for one, as the ſeaſon happens to be humid. The Huerta, or rich vale of Alicant, yields a perpetual ſucceſſion of crops. Barley is ſown in September, reaped in April; ſucceeded by maize, reaped in September, and by a mixed crop of eſculents which follow. Wheat is ſown in November, and reaped in June; flax in September, pulled in May. In the vale of Valencia wheat yields from 20 to 40; barley, from 18 to 24; oats, from 20 to 30; maize, 100; rice, 40. In the more ſouthern provinces, the land is almoſt equally fertile: and the ſugar-cane is ſucceſsfully cultivated near Granada. The Spaniſh plough is generally light, and is drawn by oxen with the yoke over the horns. All the provinces of Spain produce wine. The eaſtern and ſouthern provinces contain a vaſt number of vines; but the northern and weſtern not ſo many. But the wines vary in reſpect of quality in the different provinces, and in the ſeveral diſtricts even of the ſame province. The ordinary wines of the country are red wines; but many diſtricts of Spain produce excellent ſweet wines. The old ſherry wine, "Xerez ſeco," is the ſherry ſack of Shakſpeare. The dried grapes or raiſins form in the kingdom of Valencia, where they annually produce 88,461½ cwt. and uſually export 36,538 cwt., and particularly in that of Granada, the environs of Malaga furniſhing annually 288,461½ cwt. and exporting 240,577 cwt., a very conſiderable article of commerce. In the latter province, they are ſimply dried in the ſun, without any other preparation; in the former the grapes are ſteeped in boiling water, ſharpened with a ley made of vine-ſtems, and then expoſed to the air and ſuſpended in the ſun, till they are ſufficiently dry. Thoſe of Malaga are of a ſuperior quality, in greater eſtimation, and obtain a higher price than any other. They are naturally larger, and of a more delicate flavour than any others. The cultivation of ſugar-canes prevails on an extenſive ſcale on the ſide of Granada, where enough is grown to ſupply a conſiderable manufacture of ſugar. Formerly they had no fewer than twelve ſugar-mills between Malaga and Gibraltar, the four principal of which were at Madrid, near which place the beſt canes were produced. But the cultivation of cotton has been ſubſtituted there in the place of ſugar. Olive-trees thrive in almoſt every part of the country. The olives grown in the diſtricts of Alcala and Guadayra, in the kingdom of Seville, are larger and finer than any in Europe, and the beſt adapted for pickling. The greateſt quantity of oil is produced in the kingdom of Valencia; *viz.* 88,000 quintals, or 84,615 cwt. annually. Wood is ſcarce in the two Caſtiles, Eſtremadura and Leon. The cables of the Spaniſh veſſels are often made of eſparto from Murcia.

In Spain ſeveral economical ſocieties have been lately eſtabliſhed, particularly at Valencia and Saragoſſa, with a view to the encouragement of agriculture; and in connection with the ſociety of the latter place is a charitable bank in favour of diſtreſſed farmers. Money is advanced ſufficient to defray the expences of harveſt, and two years are allowed for returning, by inſtalments, the ſums thus advanced. This eſtabliſhment commenced its operations in June 1805, and it then diſtributed 458*l.* 2*s.* ſterling to 110 huſbandmen; and in the month of Auguſt following it had furniſhed ſixty-two horſes to an equal number of other indigent farmers. The principal economical inſtitution for the promotion of agriculture is that at Madrid.

Manufactures and Commerce.—Spain, celebrated in remote periods for the fertility of its ſoil, and the variety of its productions, was equally ſignalized by the induſtry of its inhabitants. The Greeks and Romans found this country farther advanced in all kinds of uſeful arts than they could poſſibly have imagined. It was in the city of Zoela, in the diſtrict of Tarragon, that the firſt linen ſtuffs were manufactured; and the cloths of Xativa, or San Felippo, the ancient Sœtabis, were famous through Greece and Italy. At Carthagena very fine ſtuffs were fabricated from the bark of trees; and the manufacture of woollen cloth had arrived at a high degree of perfection, and the Spaniards poſſeſſed the art of dyeing cloth of a very beautiful purple colour, which they learned of the Phœnicians, ſo that they ſupplied all Italy with this article. The Celtiberians knew the method of tempering ſteel, and nothing could reſiſt the force of their ſwords. The manufactures of Spain, however, were injured by the invaſion of the northern nations; and were again revived by the Moors, who exhibited to the Spaniards an example of genius, activity, and induſtry. The two nations, *viz.* the Moors and the Spaniards, divided between them the manufactures of Spain: thoſe of leather, linen, ſilk, &c. were almoſt wholly in the hands of the Arabs; and thoſe of arms, and articles fabricated of wool, were in the hands of the Spaniards. When the Moors were expelled in 1614, the manufactures which had flouriſhed under their direction ſunk into decay and ruin. The hiſtory of Spaniſh manufactures may be divided into three periods. The firſt commences with the re-union of all parts of the monarchy, under the reign of Ferdinand and Iſabella, in the year 1475; and extends down to the death of Philip II. in the year 1598. The ſecond compriſes the reigns of Philip III. Philip IV. and Charles II., that is to ſay, during the whole of the 17th century. The third includes the 18th century; but ſtrictly ſpeaking, it did not begin till the year 1720.

The firſt was a brilliant period for Spain; manufactures of every kind were much increaſed, and for a time they became very famous. The ſecond period witneſſed their decline and decay, and their fall was as rapid as their elevation. Spain then no longer employed foreign merchandize. The third period furniſhes an intereſting index of the efforts which were uſed for a ſeries of time to reinvigorate the national manufactures. During the firſt, Spain was in a flouriſhing ſtate; but it had not then arrived at that high degree of improvement deſcribed by the greater part of modern writers; who have affected to believe that the country then had attained the acmè of its wealth and ſplendour.

During the whole period that elapſed, from the commencement of the 14th to the cloſe of the 16th century, Spain was perfectly independent of foreign nations; manufacturing the greateſt part of its ſilk and wool, and exporting more manufactured than raw articles. But during the progreſs of the 17th century, the manufactures of cotton, linen, and hempen cloths, gloves, and ſwords, entirely vaniſhed, and by the cloſe of this century, ſcarcely the ſmalleſt veſtiges remained, ſo that Spain was abſolutely deſtitute of trade. When Philip V. aſcended the throne, the inteſtine wars during the firſt fourteen years of that monarch's reign, and the low ſtate of the national finances, prevented the government from paying any attention to the ſtate of the country in this reſpect. Some meaſures were adopted for the revival of the manufactures, when tranquillity was reſtored. Ferdinand VI. did more for this purpoſe than any of his predeceſſors, and his ſucceſſor Charles III. followed his example. The manufactures of Catalonia were the firſt that revived ſubſequent to the war waged reſpecting the right of ſucceſſion. In a ſhort period manufactures were eſtabliſhed, and by a ſpirit of rivalry quickly multiplied. By degrees new branches of manufacture were adopted in various places, and the different ramifications are numerous at the preſent day. Theſe are ſo numerous in the different provinces and towns of the country, that our limits will not allow an enumeration of them in this place. Some account of them occurs under the names of the reſpective provinces and towns, in the courſe of this work. The ſtate of Spaniſh manufactures in the 15th and 16th centuries, will lead us to conclude that commerce was then in a flouriſhing condition; and its ramifications extended to all parts of Europe. Almeria, Valencia, and Barcelona, no leſs important, in a mercantile view, than the Hanſeatic towns, puſhed their commercial concerns into Syria, Egypt, Barbary, and the Archipelago. The trade of the country, however, was at this time very much, if not wholly, in the hands of the Jews; while the Spaniards were either engaged in war, or indulging themſelves in a ſtate of peace. The Moors conducted their agricultural and manufacturing concerns, and the Jews became their merchants and bankers. The expulſion of the Jews, in the year 1492, deprived Spain of its moſt active merchants; this was followed by the expulſion of the Moors, in 1614; ſo that commerce was deprived of its active and intelligent agents, and ceaſing to be nouriſhed by the produce of the ſoil, manufactures inſtantaneouſly diſappeared. The Barbary pirates likewiſe infeſted the Mediterranean ſea, and ſeized all the Spaniſh ſhips which ſailed from the ſouthern parts; and Spain being unable to defend commerce on the coaſt, the whole trade was carried on in foreign bottoms. The government alſo had adopted a ſyſtem peculiarly calculated to paralyze commerce: it had reſtricted the colonial trade to entering by one port only on the continent, Seville firſt, and Cadiz afterwards. Moreover, during the war about the ſucceſſion, Philip V. prohibited the exportation of all the produce of the country to the nations with which he was at war. The country at different times made fruitleſs attempts for reviving its commerce. Philip was ſcarcely in quiet poſſeſſion of the throne, before he turned his attention to the revival of commerce; he encouraged manufactures, and conferred honorary rewards on trade; he granted premiums to merchants, and inſtituted commercial boards. Charles III. permitted a general trade, and moderated the duties impoſed upon imported merchandize. In 1764 he eſtabliſhed packets, which ſailed regularly every month to the Havanna and Porto Rico, and others every two months for Rio de la Plata; and allowed every packet-boat to take out half a cargo of Spaniſh produce, and return half freighted with the productions of America. The Spaniards themſelves diſplayed a ſpirit of activity and enterpriſe, of which they were thought to be altogether incapable. About the year 1728, the Caraccas company of Guipuſcoa was eſtabliſhed, and this company produced prompt and extenſive advantages. This company was ſuppreſſed about the year 1781 or 1782. In the year 1784, a new company was formed, under the firm of "the Philippines;" and the ſhips belonging to this concern ſailed from Cadiz; but though its commencement was promiſing, many unfavourable circumſtances occurred, and it ſuſtained very heavy loſſes; nevertheleſs, at the cloſe of the year 1796 it derived a profit of nearly 229,166*l.* 13*s.* 4*d.* ſterling. The internal trade of Spain is very inconſiderable, for want of ſufficient means of communication; but it carries on a foreign trade with every country in Europe. The principal tranſactions, however, are with England, Holland, Italy, France, and its American colonies. The principal articles of foreign commerce are wine, brandy, oil, ſoda, barilla, fine wool, tobacco, dried raiſins and figs, nuts, dates, ſumac, anchovies, rice, kermes, ſalt, madder, bar-iron, and anchors. Although Spain exports immenſe quantities of its agricultural productions, it ſends abroad none of its manufactured articles, but all thoſe it receives from foreign countries. The following articles are imported into Spain, *viz.* from Holland, tapes, linen-drapery, common lace, cutlery goods, and paper;—from Sileſia, linen-drapery;—from Germany, particularly Hamburgh, quantities of haberdaſhery;—from England, calicoes, iron and ſteel goods, fine cloth, cod-fiſh, and ling; —from France, calicoes, linen-drapery, ſilk-ſtockings, ſilks, camblets, and other kinds of worſted ſtuffs, fine cloths, gilded articles, jewellery, iron goods, ſteel goods, haberdaſhery, and perfumery: and Spain carries on a conſiderable trade with her American colonies. Biſcay is the only province of Spain that is interdicted a free trade with the colonies. The colonies ſupply Spain with coffee, ſugar, ſome cotton, tobacco, cocoa, leather, and particularly gold and ſilver, both in ingots and coined into money.

The manufactures and commerce of Spain are conſiderably checked by the royal monopolies, which comprehend the following articles; *viz.* broad-cloth, at Guadalajara and Brihuega; china, at the palace of the Buen Retiro; cards, at Madrid and Malaga; glaſs, at St. Ildefonſo; paper, in Segovia; pottery, at Talavera; ſaltpetre, at Madrid and various other places; ſtockings, at Valdemoro; ſwords, at Toledo; tapeſtry, at Madrid; and tiſſue, at Talavera. The king has alſo the monopoly of brandy, gunpowder, lead, quickſilver, ſealing-wax, ſalt, ſulphur, and tobacco. Moſt of the royal manufactures may be regarded as monopolies, as no private capital can vie with the treaſury.

Government, Military, and Revenue.—Spain was never governed by a king who was not of foreign origin. Monarchs either of a Gothic or Mooriſh race, French or Auſtrian, or of the royal houſe of France, have occupied the Spaniſh throne from the year 411 till the preſent day. The Goths reigned in Spain from the year 411 till 711; the Moors from 711 till 716 in part of the Aſturias, till 820 in Catalonia, till 750 in Sobrarba, till 923 in Leon, till 1073 in different parts of the two Caſtiles, till 1118 in Aragon, till 1236 in Cordova and Jaen, till 1248 in Seville, till 1264 in Valencia, till 1265 in Murcia, and even ſo late as 1492 in Granada. During the wars againſt the Moors, the Goths reigned

reigned in the Aſturias, Galicia, and finally in the kingdom of Leon till 1038.

The houſe of Navarre deſcended from the French houſe of Bigorre, which had previouſly reigned in Caſtile for ten years, united with it the crown of Leon till the year 1126. This was ſucceeded by the family of Bourbon, deſcended from the royal family of France, which reigned over theſe countries till 1555. The houſe of Charlemagne, a French family deſcended from that prince, ruled over Catalonia from the year 802 till 1132. The French family of Bigorre firſt reigned in Sobrarba, and afterwards in Aragon, from the year 750 to 1162; at that period the French family of Barcelona ſucceeded to the government, and united to the crown of Aragon that of Catalonia, and afterwards the kingdom of Valencia, over which it reigned till the year 1430. Theſe parts of Spain then came into the poſſeſſion of the princes of the French branch of Navarre, which reigned in Caſtile, and continued in their deſcendants to 1515; at which time the different ſtates of the Spaniſh monarchy were under the government of Joanna the Fooliſh, who reigned over them till her death, which happened in 1555. The Auſtrian family then poſſeſſed the throne of Spain till 1700, ſince which time it was occupied by a branch of the houſe of Bourbon, till the late revolution, which placed the crown upon the head of Joſeph I., brother of Napoleon Buonaparte, emperor of the French; but this revolution has terminated in the reſtoration of Ferdinand VII., who ſucceeded on the abdication of his father in 1808.

The Spaniſh government, which was of a limited nature, during the dynaſties of the kings of Caſtile and Aragon, afterwards became an abſolute monarchy.

Philip V. ſuppreſſed the ſtates-general, their laſt meeting having been held at Saragoſſa in the year 1720; and ſince that period no further power is left to the Cortes of Caſtile and Aragon, but the privilege of ſending deputies to the ſtates-general, whenever they are ſummoned by the monarch. The whole authority centres at preſent in the king and his miniſters; and the national affairs are conducted by the different councils appointed by the crown, which deliberate and form their plans in the capital: ſome of them poſſeſs both legiſlative and executive power, and exerciſe the double function of adviſing the king and adminiſtering the juſtice. The council of Caſtile, in this diſtribution of power, is paramount; its decrees being deciſive in the courts, but its judgments are under the controul of the king. The chief councils in Spain are, 1. That of diſpatches, called alſo the Junto, or cabinet council, being compoſed of the king and his miniſters of ſtate. 2. The council of ſtate, in which the king preſides, and of which the archbiſhop of Toledo is always a member. 3. The royal council of finances, called the Hazienda. 4. The ſupreme council of war. 5. The ſupreme council of Caſtile. 6. The ſupreme council of Aragon. 7. The ſupreme council of the inquiſition. 8. The royal council of the orders of knighthood. 9. The royal council of the Indies. 10. That of the cruſade, compoſed of a commiſſary-general, a member of the council of Caſtile, and another of that of Aragon, who manage the ſale of little papal bulls, granting certain indulgences to the purchaſers. In Spain there are five miniſters of ſtate; correſponding to our foreign ſecretary, ſecretary for the home department, ſecretary at war, firſt lord of the admiralty, and chancellor of the exchequer, or prime miniſter.

The laws of Spain are contained in ſeveral ancient codes; and recourſe is alſo had to the civil and canon law. The "Eſcrivanos," or attorneys, are numerous, but inſtead of explaining the codes, they often impede the adminiſtration of juſtice. Miſtaken mercy frequently retains criminals in long durance, ſo that when they are executed their offence is forgotten, and the example of puniſhment has no effect.

With reſpect to the military of Spain we may obſerve, that when Philip V. aſcended the throne, there were not 15,000 troops in the kingdom, and it had not a ſingle ſhip of war fit for the ſea. This prince directed his attention to military arrangement and diſcipline; and his ſucceſſors, by following the ſame courſe, have obtained a reſpectable army; and by the increaſe and ſtrength of its naval inſtitutions, Spain has alſo become a maritime power. In the year 1807 the army ſtaff included 5 captains-general, 5 inſpectors, 87 lieutenant-generals, 128 field-marſhals, and 213 brigadier-generals, beſides military intendants, military commiſſioners, treaſurers of the army, military judges, &c. The military eſtabliſhment of the royal houſehold conſiſts of four companies of life-guards, a company of halbardiers or ſpearmen, a regiment of infantry called the Walloon guards, and a regiment of cavalry called the royal carabiniers. The life-guards are divided into four companies, the Spaniſh, the American, the Italian, and the Walloon; and each conſiſts of natives of theſe reſpective countries. The militia is diſtinguiſhed by the appellations of milices provinciales, or provincial militia, divided into 42 battalions, and diſtributed through the different provinces, and the milices urbanas, or civic militia, which neither receive pay nor are liable to be called away from their homes. The Spaniſh troops all wear a red cockade, except the Walloon and Swiſs guards; that of the former being red and black, and that of the latter red and yellow. The whole military force of Spain, in time of peace, is computed at about 60,000. The naval forces of Spain conſiſt of a marine ſtaff, a corps of marine officers, a corps of naval cadet-guards, and three corps of engineers, artillery, and infantry, appropriated entirely to the ſervice of the navy. The ſhips of the line can ſcarcely now be computed at more than 50.

The revenues of the king of Spain, on the continent, conſiſt in monies ariſing from his own landed eſtates, cuſtoms, all kinds of taxation, &c.; which revenues amount at preſent, for the whole of Spain, to 8,097,813*l.* 6*s.* 4*d.* ſterling, without including various conſiderable ſums from different ſources, which cannot be aſcertained, for want of accurate information. The king of Spain alſo derives conſiderable revenues from the two Indies; but the expence of collecting, &c. is ſo great as to abſorb nearly two-thirds. The total revenues of the Spaniſh colonies amount to 27,000,000 piaſtres fortes; and deducting expences, ſcarcely more than 9,000,000 piaſtres arrive at the royal treaſury. The revenue of Spain has been ſtated by ſome writers at 5,500,000*l.* ſterling, ſo that each perſon pays 10*s.* to government for protection. For the nature of the taxes we may refer to Laborde and Townſend's tables. The gabel is one of the moſt productive; and the clergy pay about 15,000,000 of rials. The expenditure now equals, or exceeds the income; and the national debt gradually enlarges. The colonies, as ſome of the beſt judges have eſtimated them, do not yield above 1,000,000*l.* ſterling, excluſive of the duties. Bourgoing computes the revenues of Spain at 616,295,657 rials, and its money in circulation he ſtates at 80,000,000 of dollars; eſtimating the rial at 5 ſous of France, and the dollar at 20 rials.

Religion and eccleſiaſtical Government.—The religion of Spain is the Roman Catholic, profeſſed with a degree of fanaticiſm which exceeds that of any Italian ſtate, or even the Papal territory. The inquiſition, eſtabliſhed in 1480, by Ferdinand and Iſabella, and lately reſtored with the return of the preſent ſovereign, after its abolition, has produced the moſt injurious effects; and the number of monks, under the obligation of celibacy, but under the influence of exiſting paſſions, has been very detrimental and even deſtructive to morals. The number of the Spaniſh clergy has been variouſly ſtated by different writers. Mr. Townſend ſtates it at 188,625; others compute the clergy at 400,000. Laborde, in a table drawn up from the enumeration of them in 1788, reckons the ſecular clergy at 60,238, the miniſters of churches at 15,834, the monks of 1925 convents at 49,238, and the nuns of 1081 convents at 22,347; and reckoning the population at 11,000,000, the clergy of Spain form one-ſixty-ninth of the whole. Spain is divided into eccleſiaſtical provinces, over which preſides an archbiſhop, with the rank of metropolitan: theſe provinces are again ſubdivided into dioceſes, each of which is governed by a biſhop. The archbiſhoprics are eight in number, and the ſuffragan biſhoprics are forty-four. The archiepiſcopal ſeat of Toledo is the firſt in rank, and the wealthieſt in Spain: it confers on its poſſeſſor the title of primate, and a revenue of about 125,000*l.* ſterling. The Moſarabic ritual, adopted in Spain, on the expulſion of the Arabs, declined after the introduction of the French princes, and was finally ſuperſeded by that of the Romiſh church. It ſtill ſubſiſts, however, at Salamanca and Toledo, where are two chapels ſerved by a numerous body of clergy, in which public worſhip is performed according to this ancient form.

The Spaniſh nation recognizes no authority or juriſdiction of the pope in the temporal concerns of eccleſiaſtical benefices. No briefs nor bulls are received, publiſhed, or executed in Spain, unleſs they have been examined by the chamber of Caſtile, and have received its *exequatur*, or licence.

In conſequence of the ſame concordat, and of various briefs and royal edicts founded upon it, the king at preſent nominates not only to thoſe benefices, the patronage of which belongs to the crown, but alſo to all the benefices in the patronage of the church, which become vacant during any of the eight months formerly reſerved by the pope, as well as to all thoſe that become vacant, in conſequence of the former incumbents having been promoted by the king: the crown alſo iſſues licences, to enable thoſe who are nominated to take poſſeſſion of their preferments. The revenues of conſiſtorial benefices, during their vacancy, go to the crown, on condition of their being applied to charitable uſes. The annates, demi-annates, and quindennes, belong to the king, who alſo has the right of granting penſions on the archbiſhoprics and biſhoprics, to the amount of one-third of their entire revenue.

The pope, however, ſtill preſerves in Spain two very important privileges, namely, the ſupreme adminiſtration of the *contentious juriſdiction* over all caſes that are brought before the eccleſiaſtical tribunals, and the free and independent nomination to fifty-two of the beſt benefices. The impoſts of various kinds and denominations, payable by the clergy of Spain, amount annually to about 437,840*l.* 18*s.* 2*d.* ſterling, excluſively of ſome other charges. Burgoing. Townſend. Fiſcher. Laborde. Pinkerton.

Hiſtory of the Muſic of Spain.—It ſeems as if a late muſical hiſtorian had placed the Spaniards lower among European muſicians, in the 15th and 16th centuries, than in equity they ought to have been, by imagining Morales the firſt practical muſician of eminence in that country, and Salinas the only theoriſt that was produced there during the 16th century. (See MORALES.) Indeed we know but little of the ſtate of muſic in the interior parts of that kingdom, during this period; but, if we may judge by the muſicians it furniſhed to the Papal chapel, both compoſers and ſingers, we may conclude, that the richeſt and moſt powerful nation in Europe, as Spain then was, would not breed muſicians as the Africans do ſlaves, or the Circaſſians women, merely to tranſport them for the uſe or pleaſure of others; they could doubtleſs then have afforded to keep a few for their own amuſement.

The Spaniards, ſo far from neglecting muſic, ſeem to have taken it very early into the circle of the ſciences, in their univerſities; for Salinas tells us, that the muſical profeſſorſhip, which was conferred upon him at Salamanca, had been founded and endowed by Alphonſo, king of Caſtile, ſurnamed the Wiſe. And Bartolomeo Ramis, the opponent of Franchinus, in 1482, was public profeſſor of muſic at Toledo, and afterwards at Bologna. Of Guillerm de Podio, a prieſt, we have likewiſe a work, entitled "Ars Muſicorum, ſive Commentarium Muſicæ Facultatis," publiſhed 1495; and another written in the Spaniſh language, by Franceſco Trovar, "Libro di Muſica Pratica," Barcelona, 1519; "Arte di Canto Llano," del Alfonſo de Caſtillo, Salamanca, 1504; "El Maeſtro o Muſica de Viguela de Mano," by Don Ludovicus Milan, a nobleman of Valentia, 1534; "Silva di Sirenas," or a treatiſe on the vitruela, or viol, by Henrico de Valderrabano, Valladolid, 1547; "Arte de la Muſica," by Melchior de Torres, alcala de Herrares, in New Caſtile, 1554. At the ſame place likewiſe was publiſhed, in 1557, "Tratado de Cifra nueva para Tecla, Harpa y Vieguela Canto Llano, de Organo y Contrapunto," by Lud. Venegas de Hineſtroia. There was likewiſe publiſhed at Alcala, by Cyprian de la Huerga, a Ciſtertian monk, who died 1560, a treatiſe "De Ratione Muſicæ et Inſtrumentorum Uſu apud veteres Hebræos;" and at Granada, 1555, "Libro de la Declaration de Inſtrumentos," by Joan Bermudo.

All theſe writers on the ſubject of muſic, and many more, appeared in Spain before Salinas; of whom an account is given under his biographical article.

Many more names of Spaniſh theoriſts and practical muſicians might be enumerated here; but as we have neither ſeen nor heard any of their productions, we are unable to eſtimate their worth. In 1613, however, a work was publiſhed in Spaniſh, by Cerone, in folio, which contains more information concerning every part of the art and ſcience then known, than any other elementary book which we have ſeen in any language. The title of this treatiſe is the following: "El Melopeo y Maeſtro. Tractado di Muſica teorica y pratica," Napoli, 1613. See CERONE.

Andres Lorente was author of a treatiſe, now become very ſcarce, entitled "El Porque del la Muſica," 4to. 1672. For a farther account of this book, ſee LORENTE, and *Dr.* WORGAN.

Pablo de Zaragoça Naſſarre was author alſo of a treatiſe on muſic, in Spaniſh, entitled "Fragmentos Muſicos," in four parts, a diſtinct treatiſe, 4to. Madrid, 1700. For a further account of this work, ſee NASSARRE.

About the middle of the laſt century was publiſhed at Madrid, in Spaniſh, "An Eſſay on Church Muſic," by Feyjoo. We have never ſeen the book in the original, but an anonymous tranſlation into Engliſh appeared in 1778. The author begins with a heavy complaint againſt the corruption and degeneracy of muſic, ancient and modern; joining with Plutarch in aſſerting, that muſic was at firſt only uſed in the temples of Greece; but paſſing to the theatre, a new and lighter ſtyle was invented, which being adopted in the temple, rendered it unfit for the ſerious ſervice of religion. It was not till the latter end of the 17th century, that ſecular muſic, by additional refinements in ſinging, and improvements in inſtrumental muſic at the opera, was thought worthy of being introduced, on great feſtivals, into the church, in Roman Catholic countries: on other days, canto fermo, and maſſes ſet alla Paleſtrina, were continued, and are ſtill continued in the cathedrals of Italy; though, even in the 16th century, maſſes *concertati*, or accompanied with a band of inſtruments, according to Montaigne, (Journal d'un Voyage,) were common throughout Italy and Germany.

We know not what the ſtate of eccleſiaſtical muſic may be in Spain at preſent; but we have always underſtood that the muſic, *à capella*, in Spain, was more ſolemn and learned than elſewhere. The poet Yriarte, whoſe judgment and taſte are correct and elegant, and who has no prejudices, except in favour of good muſic of every kind and country, ſpeaks highly of the muſic of the church in Spain.

But Feyjoo's Eſſay is conſtant complaint and cenſure. Yet from the time of Charles V., an excellent muſician himſelf, the Spaniſh monarchs have patronized muſic in a more diſtinguiſhed manner, both in the church and the theatre, than any other ſovereigns in Europe, till the late Charles VI., an *amouſos*, who ſucceeded Ferdinand IV., and who turned Farinelli out of the kingdom, whoſe good conduct merited equal praiſe with his talents. See FARINELLI.

The author before us aſks, whether all the muſic of the church ſhould not be grave? We anſwer, no; not invariably. Are there not days and pſalms of jubilation and thankſgiving, as well as of penitence, ſorrow, and ſupplication! As the Calviniſts confine all muſic to ſyllabic pſalmody, this pious Spaniard would have no other muſic tolerated in the church than canto fermo.

We own the impropriety, and have cenſured it, in the admiſſion of ſecular muſic in our cathedrals during the reign of Charles II. and his ſucceſſors; when, in the compoſitions of Weldon and Dr. Greene, the diviſions and ritornels wanted due gravity and dignity, and were manifeſtly introduced to diſplay an active throat and a lively finger, for want of judgment and decorum in the compoſer, who forgot the place and occaſion of the performance.

The Spaniſh writer very juſtly cenſures the admitting into the church the productions of inſipid pretenders to compoſition, without genius or ſcience; and finds, as is found every where elſe, that the number of bad compoſers and bad performers ſo far exceeds the good, that men of true genius and due cultivation are phenomena that rarely appear. Don Feyjoo has celebrated a Spaniſh compoſer, Don Antonio de Literes, whoſe name has never penetrated into other parts of Europe, in the higheſt terms of panegyric.

The Eſſay on Church Muſic was written about the middle of the laſt century, when the general ſtyle of Italy was frivolous, and that of Germany rude, pedantic, and inelegant; but ſo many great compoſers have appeared ſince in both countries, that Don Feyjoo's ſtrictures have loſt their force. There have been bad compoſers in all ages, but perhaps never more good ones at any period of time, than within the laſt 30 years.

Duron, the author, we ſuppoſed, meant Durante, was not only one of the greateſt maſters of harmony himſelf, but formed diſciples of the greateſt abilities that have ever iſſued from the Neapolitan ſchool; but we find in Yriarte, that there had been among the maſters of former times a Spaniſh compoſer of the name of Duron.

The reſt of this Eſſay is exaggeration of invective, either to mortify Farinelli, and the great Italian compoſers and ſingers whom he engaged for the court of Spain, or to flatter the ſucceſſor of Ferdinand, who hated muſic, and expelled all the Italian muſicians from his court.

The ſame anonymous gentleman has given us a tranſlation of a letter of the learned Benedictine on the ſubject of muſic, entitled "The wonderful Effects of Muſic, and a Parallel between ancient and modern Muſic."

Here the author relates all the old ſtories of the miraculous powers of ancient muſic. He, however, doubts of the facts; and relates, *per contra*, what we have been told of the power of modern muſic over diſeaſe and the paſſions.

No new materials appear in this letter, or ingenious conjectures to determine the diſpute, whether the ancients or the moderns had cultivated muſic moſt ſucceſsfully; and the author leaves the ſubject juſt as he found it, without clearing up his own doubts, or thoſe of his readers. He is always, however, inclined to give the preference to ancient muſic, without any thing to guide him but his prejudice, his determination to allow nothing that is new in muſic to be right, and the aſſertions by writers in favour of ancient counterpoint, that have been long ſince clearly confuted.

The laſt writer on muſic in Spain, that has come to our hands, is the ingenious and agreeable poet, Yriarte, of whoſe charming poem, "La Muſica," we but lately procured the beautiful third edition, printed at the royal preſs in Madrid, in 1789, with elegant deſigns well engraved.

As this is a work but little known in our country, and does honour to the author, and to the art of practical muſic in all its branches, we ſhall be ſomewhat diffuſe in our account of it.

D. Tomas de Yriarte writes like a man of the world, with an enlarged taſte, and extenſive knowledge of the ſubject. He has illuſtrated his doctrines from the moſt eminent moderns. Canto I. gives an outline of the general hiſtory of the muſical art; calls on muſic itſelf to inſpire and aſſiſt him, without applying to Apollo and his nine attendants, or even repeating old fabulous accounts of the miracles performed by Orpheus, Amphion, Linus, Terpander, or Olympus.

He deſcribes the importance of *tone* and *time*. The firſt includes the formation of the ſcale, and its diviſions into intervals; the ſecond, the time-table, or muſical characters for meaſuring the duration of ſounds.

II. Muſical expreſſion; its uſe in the church, the theatre, the chamber, and to man alone; its powers over the paſſions.

III. The dignity and uſe of muſic, particularly in the temple, the theatre, in ſociety, and in ſolitude; enumeration of celebrated ancient Spaniſh compoſers.

IV. Uſe of muſic in the theatre reſumed; Jomelli; dancing, architecture, painting, poetry, decorations; modern compoſers for the lyric theatre celebrated.

V. Uſe of muſic in private ſociety; eulogium on ſilence at concerts, and invective againſt thoſe who attend not with due reſpect for the art and for talents; of opera ſcenes in concerts; of inſtrumental muſic proper for a concert-room; ſonata, concerto, duo, trio, quartetto, ſymphony; neceſſity of variety and foreign muſic to keep off languor, and excite attention; praiſe of the German compoſers of inſtrumental muſic, particularly Haydn for invention; of the utility and delight which muſic affords in ſolitude, as well to thoſe that are ignorant, as thoſe that are learned in the art; of the ſtudy neceſſary for a good compoſer in examining the ſcores of celebrated authors, to detect errors and plagiariſm, as well as to diſcover how good effects are produced; cenſures the pedantry of dry fugues and canons, that have no other merit than the difficulty of compoſing them; extraneous modulation; confuſion of multiplied parts in different ſtyles and movements, which deſtroy the effect of each other; recommends the avoiding of all exceſſes of all kinds, as harmony, literally and figuratively, implies *juſt proportion;* celebrates the good taſte which is manifeſt in the Royal Academy at Madrid, in the public diſtribution of premiums to artiſts in painting, ſculpture, architecture, and engraving; to which have been added poetry and eloquence. It is propoſed, in addition to all theſe arts, to eſtabliſh an academy, or ſcientific body of muſic.

In the courſe of this laſt canto there is an animated eloge on Haydn.

> " Sólo á ta múmen, Háyden prodigioſo," &c.
>
> " To thee alone the muſes have conſign'd
> A genius ever fertile and refin'd;
> So new thy ſtrains, ſo copiouſly inſpir'd,
> That curioſity is never tir'd;
> Thy works a thouſand times repeated, ſtill
> With rapture new experienc'd ears can fill.
>
> To ſooth, to calm, or noble deeds inſpire,
> Thy fancy ſtill is fed with heaven's own fire.
> In every trait a judge profound can find
> Some grace or beauty of a higher kind;
> Expreſſion touching, modulation new,
> In themes which none but gifted men purſue.
>
> Surrounded by thy countrymen renown'd,
> In thee alone the liſtening world has found
> A power to intereſt, and render dear
> Each ſweet vibration of th' enraptur'd ear.
> To diſtant climes the happy means convey,
> As light and heat ſent forth from ſolar ray.
> And while theſe inſpirations wide expand,
> Conferring honours on thy native land."

SPAITLA, a town of Africa, in the kingdom of Tunis, anciently called " Sufetela," repreſented by Dr. Shaw as one of the moſt remarkable places in Barbary for the extent and magnificence of its ruins. Here are found a triumphal arch of the Corinthian order; a pavement of large black ſtone, with a breaſt-high parapet on each ſide, which leads from the arch to the city; a beautiful portico at the end of the pavement, opening into a ſpacious court; the ruins of three contiguous temples, of which the columns, pediments, and entablatures are entire, &c. &c. Spaitla is pleaſantly ſituated upon an eminence, ſhaded all over with juniper-trees; 110 miles S.W. of Tunis. N. lat. 35° 10′. E. long. 9° 10′.

SPALATRO, a ſea-port of Dalmatia, ſituated on a peninſula, with a good harbour; the ſee of an archbiſhop. The harbour is large and deep, and well frequented by foreign veſſels, which come for merchandize from Boſnia, ſuch as iron, hides, wrought copper, wool, blankets, bees-wax, orpiment, ſilk, cotton. Spalatro is built on the ruins of Diocleſian's palace, for an account of which ſee SALONA. Without the walls is a ſulphureous ſpring, of conſiderable ſervice in chronical diſeaſes. N. lat. 43° 22′. E. long. 16° 45′.

SPALDING, an ancient and reſpectable market-town in the wapentake of Elloe, parts of Holland, and county of Lincoln, England, is ſituated 8 miles W. from Holbeach, 41 miles S.E. from Lincoln, and 101 N. from London. Being in the midſt of a fenny diſtrict, and almoſt encompaſſed by the river Welland, and an ancient drain called the Weſtlode, and having numerous other drains in its vicinity, Spalding has been, with ſome degree of propriety, compared to a Dutch town. Though thus ſituated, and not apparently congenial to healthfulneſs, its claim to antiquity is teſtified by many remains diſcovered in and about the town. That it certainly exiſted before the foundation of Croyland abbey, is evinced by king Ethelbald's charter to that monaſtery, deſcribing its bounds as extending " uſque ad ædificia Spaldeling." Prior to the Conqueſt the manor was the property of Algar, earl of Mercia; but was granted by the conqueror, with the whole of the diviſion of Holland, to his nephew, Ivo Tailbois, who erected a caſtle here, of which the moat was to be diſtinguiſhed in 1746, in that part of the Caſtle-fields called Coney Garth. In the year 1051, Thorold de Bukenhale founded and endowed a priory here, and made it a cell to Croyland; but the inhabitants were forced to abandon it after the Conqueſt, through the oppreſſion of Tailbois, who about 1074 gave the church and manor to the abbey of St. Nicholas at Angiers, whence ſome Bendictine monks were ſent over, and it became an alien priory. It was in ſucceeding times a monaſtery of great conſequence. From this place Egelric, abbot of Croyland, made a firm cauſeway, named Elrick-road, through the marſh called Arundel foreſt, to Deeping, being an extent of twelve miles. It was formed by driving in piles of wood, which were covered with gravel. This road is now diſtinguiſhed by the name of " The Gravel." The conventual church not being ſufficiently large, the prior pulled it down in 1284, and built the preſent pariſh church, which is a light ſtructure, with a handſome ſpire, having crockets at the angles: the porch appears to have been added about the end of the 15th century. A free grammar-ſchool was erected in the reign of Elizabeth, by the will of John Blanch. Another, called the Petty ſchool, was founded in 1682, by Thomas Welleſley; here is alſo a blue-coat charity-ſchool. An alms-houſe for twenty-two perſons was founded in 1590; and another for eight widows in 1709.

For many centuries Spalding has been the principal ſeat of juriſdiction for the diviſion of Holland. In the Saxon times the courts of law were held here by the earls; and ſubſequent to the Norman Conqueſt, the priors were inveſted with the judicial authority: even capital offences were cognizable in the conventual court. But at the diſſolution of religious houſes, the power of deciding on life and death was removed from all ſuch inferior courts. Since that time a court of ſeſſions has been held here; for which purpoſe a town-hall, or court-houſe, was erected, at the expence of Mr. John Holſtan, at the north-weſt end of the market-place; the upper rooms are uſed for the quarter-ſeſſions, the courts-leet and baron, and the courts of requeſt and ſewers; the lower part of the building is let out for ſhops, and the rents appropriated to the uſe of the poor, conformably to the will of the donor. Spalding, ſince the river Welland has been made navigable to the town, has had a good carrying and coaſting trade. Barges of about 40 tons burthen come up to the centre of the town, where are quays and ſpacious ſtore-houſes: but veſſels requiring a larger draught come only to Boſton Scalp, nine miles diſtant. Attempts have been made to introduce manufactures into Spalding, but without ſucceſs: the town derives its chief ſupport from agriculture, and the extenſive grazing carried on in its neighbourhood. Wool conſequently forms a very prominent article in its trade; and ſome of the manufacturing towns of Yorkſhire and Norfolk are ſupplied from hence. A market is held on Tueſdays, and five fairs annually, beſides two ſtatutes for hiring ſervants. In the population return of the year 1811, the number of houſes was ſtated to be 951; the inhabitants 4330.

A literary ſociety was eſtabliſhed at Spalding in the beginning of the laſt century, under the auſpices of Mr. Maurice

Johnſon, an eminent native of this town, on the principle of that of the antiquaries of London; to which tranſcripts of the minutes and records were regularly ſent for upwards of forty years, till the death of Mr. Johnſon, which happened in 1755.

In the vicinity of Spalding is Ayſcough Fee-Hall, the reſidence of Maurice Johnſon, D.D., a deſcendant of Mr. Johnſon above-mentioned. The manſion was built about 1420, but having been altered at different times, exhibits ſcarcely any thing of its original architecture. The preſent poſſeſſor has, however, endeavoured to reſtore it to its ancient character.

At Pinchbeck, about three miles north of Spalding, are ſome conſiderable remains of an ancient manſion, formerly called Pinchbeck-Hall, from a family of that name. Being afterwards poſſeſſed by the Otway family, it acquired the appellation of Otway-Hall. It appears to have been an extenſive ſtructure, and to have been built about the time of Henry VIII. It was moated round, and ſome of the windows have pointed lights with ſquare heads. The chimnies are ſingularly lofty, and the gable ends have at the ſides and centres, ſpire-ſhaped ornaments, crowned with ornamental balls. Beauties of England and Wales, vol. ix. Lincolnſhire, by J. Britton, F.S.A.

SPALES, Cross-spales, in *Ship-Building*, are deals or fir-planks, nailed in a temporary manner to the frames of the ſhip, at a certain height, and by which the frames are kept to their proper breadths, until ſome of the deck-knees are faſtened. The main and top-timber-breadths are the heights frequently taken for ſpaling the frames, but that of the gun-deck ports is much better; yet this may be thought too high, if the ſhip is long in building.

SPALETHRA, or Spalathra, in *Ancient Geography*, a town of Greece, in Theſſaly. Steph. Byz. Scylax ſtates it to be a maritime town of Magneſia.

SPALMADORI, in *Geography*, a ſmall iſland in the Grecian Archipelago, between the iſland of Scio and the continent of Aſia. N. lat. 38° 36′. E. long. 26° 7′.

SPALT, a town of Bavaria, in the biſhopric of Aichſtat; 16 miles E.S.E. of Anſpach. N. lat. 49° 7′. E. long. 10° 52′.

SPAN, a meaſure taken from the ſpace between the thumb's end and the tip of the little finger, when both are ſtretched out.

The ſpan is eſtimated at three hands' breadths, or nine inches.

Span, in *Rigging*, a ſhort rope, having a block, thimble, or eye, ſpliced into each end: the middle is hitched round a maſt, yard, gaff, cap, or ſtay, from whence the ends branch out. Spans are ſometimes faſtened at both ends, and a block, &c. in the bight. They are uſed to lead ropes through, which paſs through blocks or thimbles, to increaſe power, or to prevent their ſwinging about. *Spanning of booms*, is confining them by ſeveral turns of rope. *Spanning of runners*, is taking ſeveral turns with ſmall rope round both runners, abaft the maſt, and frapping the turns.

Span-*Shackle*, a bolt having a large ring in the head of it.

SPANANTHE, in *Botany*, a genus of umbelliferous plants, received by Jacquin from the Caraccas, and ſo named by him, from σπανος, *rare*, and ανθος, *a flower*, becauſe of the ſcarcity of this tribe in tropical countries.—Jacq. Coll. v. 3. 248. Sprengel Umbellif. Prodr. 34.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Umbelliferæ*.

Gen. Ch. *Cal.* Umbel ſimple, of ſeveral rays; involucrum of ſeveral lanceolate leaves; perianth of five ovate, acute, permanent leaves. *Cor. Univerſal* uniform; all the flowers perfect and fertile; *partial* of five lanceolate, inflexed petals, channelled at the back. *Stam.* Filaments five, awl-ſhaped, erect, about as long as the petals; anthers roundiſh, of two lobes. *Piſt.* Germen inferior, ovate, rather compreſſed, with two lateral furrows, prominent, blunt and divided at the ſummit; ſtyles two, awl-ſhaped, divaricated, ſhorter than the ſtamens; ſtigmas ſimple. *Peric.* none; fruit ovate, ſolid, tranſverſely diviſible into two parts. *Seeds* two, five-ribbed, contracted at their conjunction, convex at their ſides.

Eſſ. Ch. Umbel ſimple. Involucrum of many leaves. Perianth of five permanent leaves. Petals undivided. Fruit oblong-ovate, ſolid. Seeds five-ribbed; contracted at their conjunction; convex at the ſides.

1. S. *paniculata*. Panicled Spananthe. Jacq. Coll. v. 3. 247. Ic. Rar. t. 350. (Hydrocotyle Spananthe; Willd Sp. Pl. v. 1. 1363. Ait. Hort. Kew. v. 2. 118.)—Native of the Caraccas, according to Jacquin. It was alſo found in moiſt places near Lima, by Dombey, one of whoſe ſpecimens, under the name of *Phellandrium ciliatum*, was given to the younger Linnæus. We received a living one from the ſtove at Kew, in October 1790, an earlier period by five years, than is marked for the introduction of this curious plant by Mr. Aiton. The *root* is biennial, conſiſting of many fibres. *Stem* from one to three feet high, erect, branched, leafy, round, ſtriated, ſmooth, hollow; ſometimes partly zigzag. *Leaves* alternate, on long ſtalks, ſimple, triangular, or ſomewhat heart-ſhaped, from one to three inches broad, pointed, copiouſly ſerrated; entire at the baſe; reticulated with numerous veins, which, on the upper ſide eſpecially, bear a greater or leſs number of briſtly hairs; the under ſide is paler and nearly ſmooth. The inſertion of the *footſtalk* is marked with a tuft of briſtly hairs. *Stipulas* oblong, membranous, fringed, united to the baſe of the footſtalk. *Umbels* ſimple, ſmall, on long ſtalks, variouſly collected into branched panicles, or ſometimes irregular compound umbels, accompanied by ovate, or lanceolate, ſerrated *bracteas*. *Petals* white, inflexed, and partly heart-ſhaped; by no means ſo flat and ſpreading as in Jacquin's figure, from whence his deſcription ſeems to be taken. We have not ſeen the ripe *fruit*, and have therefore been obliged to form our deſcription thereof from Jacquin and Sprengel. The latter, in the *Prodromus* of his new arrangement of the *Umbelliferæ*, of which we hope to ſpeak hereafter, in its proper place, has widely ſeparated this plant from *Hydrocotyle;* and we have already, ſee Hydrocotyle, n. 13, hinted a doubt on this ſubject, which was ſuggeſted by the very different habit of *Spananthe*. But ſurely the learned author laſt named has widely erred, in claſſing *Hydrocotyle* among the genera with compreſſed flat fruit, like *Tordylium*, *Heracleum*, &c. Its fruit indeed is compreſſed, but tranſverſely, not laterally, ſo as not to differ in that reſpect from the preſent genus; which, however, appears to us ſufficiently marked by its large and permanent *perianthium*, to ſay nothing of the more oblong, and not ſemi-orbicular, ſhape of its *ſeeds*. If we were furniſhed with theſe in a perfect ſtate, we ſhould probably find other diſtinctive characters.

SPANCEL, in *Rural Economy*, a term ſignifying a rope to tie a cow's hinder legs while milking, &c.

SPANDAU, in *Biography*, a very pleaſing and extraordinary performer on the French horn, in the ſervice of the ſtadtholder at the Hague in 1772, who in 1773 came to England, where he was heard with the greateſt pleaſure. He contrived in his performance ſo to correct the natural imperfections of the horn, as to make it a chamber inſtrument. He played in all keys, with an equality of tone, and as much accuracy of intonation in the chromatic notes, as could be done on a violin ; by which means, and his delicacy, taſte, and expreſſion, he rendered an inſtrument which, from its force and coarſeneſs, could formerly be only ſupported in the open air, in theatres, or ſpacious buildings, equally ſoft and pleaſing with the ſweeteſt human voice. In 1783 ſome exquiſite pieces for the horn of his compoſition were circulated in MS. from the German and Dutch muſic-ſhops ; but we believe they were never printed.

SPANDAU, in *Geography*, a town of Brandenburg, in the Middle Mark, ſituated on the Havel, at its union with the Spree. This town, though not large, is both flouriſhing and populous, with a conſiderable foundery of arms ; 11 miles N.E. of Potſdam. N. lat. 52° 33′. E. long. 13° 11′.

SPANDEN, a town of Pruſſia, in Oberland ; 14 miles E. of Holland.

SPANDONCEA, in *Botany*, a genus ſo called by profeſſor Deſfontaines, in honour of M. van Spaendonck, botanical draughtſman at the Royal Garden of Paris. This genus had previouſly been named in Italy *Panciatica*, and originally by Forſkall *Cadia ;* which laſt appellation, though of Arabian origin, has been retained. See CADIA.

SPANDRIL, in *Architecture*, the open ſpace between the outward moulding of an arch, from its impoſt to the horizontal member or line which ſurmounts it.

SPANGENBERG, in *Geography*, a town of the principality of Heſſe Caſſel ; 17 miles S.E. of Caſſel. N. lat. 51° 8′. E. long. 9° 36′.

SPANGLES *for Paper-hangings*. See PAPER-*hangings*.

SPANHEIM, FREDERIC, in *Biography*, an eminent theological profeſſor, was born in 1600, at Amberg, in the Upper Palatinate, where his father held an office in the electoral court. He ſtudied at Heidelberg and Geneva, and in 1621 engaged himſelf as preceptor in the family of the governor of Ambrun, in Dauphiné, where he remained three years. From thence he paſſed to Paris, and afterwards paid a viſit to England, and returning to Geneva, he obtained a chair of philoſophy in the college in 1626. Soon after this he was admitted a miniſter, and in 1631 he ſucceeded M. B. Turretin in the profeſſorſhip of theology at Geneva. The reputation which he acquired in the exerciſe of this office procured him various invitations, and having accepted one from the univerſity of Leyden, he removed thither in 1642. In this ſituation he augmented his former reputation, as well by his lectures and ſermons, as by the works which he compoſed. He paſſed a very laborious life, and died in the 50th year of his age. He was ſuppoſed to have ſhortened his days by the greatneſs of his labours, which are thus deſcribed. " He gave public lectures in theology four times a week, and private lectures of different kinds to his pupils ; he examined candidates, and preached in two languages, *viz.* the German and the French : he was accuſtomed frequently to viſit the ſick, wrote a vaſt number of letters, and would compoſe, at the ſame time, two or three books on different ſubjects : he aſſiſted every Wedneſday at the prince of Orange's council at the Hague, and was rector of the univerſity. Amidſt all theſe various occupations, he found leiſure to keep the accounts of his houſe, which was always well filled with boarders." Spanheim was a man of great learning and capacity, and he is thus characterized by Saumaiſe, who felt no love for him. " He had a ſtrong head, well filled with erudition : he was fitted for buſineſs, firm, ardent, and induſtrious. He was a rigid opponent of all that he regarded as innovation in doctrine ; and readily entered into controverſy, not only with the enemies, but with the friends of the church, when he ſuſpected that they deviated from orthodoxy." He never, it is ſaid, ſuffered philoſophy to intrude into the myſteries of theology, but exerted all efforts to keep the latter uncontaminated. His works were very numerous, and on divers ſubjects : ſome were political, as " Le Soldat Suedois," compoſed at the requeſt of the Swediſh ambaſſador ; " Mercure Suiſſe ;" " Commentaire hiſtorique de la Vie et de la Mort de Chriſtople, Vicomte de Dhona ;" " Memoires ſur la Princeſſe Louiſe Juliane, Electrice Palatine." Theſe were all publiſhed without his name : of his theological works, the principal is one on " Univerſal Grace ;" " Dubia Evangelica ;" " Epiſtola ad Buchananum de controverſiis Eccleſiæ Anglicanæ ;" " De Autore Epiſtolæ ad Hebræos."

SPANHEIM, FREDERIC, ſecond ſon of the preceding, was born at Geneva in 1632, was likewiſe a profeſſor of theology of high reputation. He ſtudied under his father at Leyden, and began his career as a preacher in 1652, and by his overbearing eloquence, excited the jealouſy of Alexander More, then famous in the United Provinces. Receiving an invitation from the elector-palatine to occupy the chair of theology at Heidelberg, he took the degree of D.D. at Leyden in 1655, and then took poſſeſſion of his poſt. He acquired the eſteem and confidence of the elector ; and it is to the honour of both, that he did not forfeit them when he was the only perſon who ſtrongly and firmly oppoſed that prince's deſign of divorcing his wife, and remarrying. He received invitations from ſeveral other univerſities, and accepted that from Leyden in 1670, when he was made profeſſor of theology and ſacred hiſtory, in performing the duties of which he acquired a very high reputation. His life was diſquieted by ſome controverſies in which he engaged, and into which none ſhould enter who have not ſtrong nerves, that will bear to be aſſailed by the weapons of an enemy. For ſeveral years before his death he was allowed to omit his duties as lecturer, in order that he might devote his whole time to learned writings. Theſe were ſo numerous, that when collected, they filled three volumes in folio, which were printed at Leyden in 1701-3 ; in the former of theſe years the learned profeſſor died. Among his works the moſt eſteemed is a ſummary of eccleſiaſtical hiſtory of the 16th century.

SPANHEIM, EZEKIEL, an eminent ſcholar and ſtateſman, eldeſt ſon of Frederic, was born at Geneva in 1629. He accompanied his father to Leyden in 1642, when he was already far advanced in the knowledge of the learned languages, and he ſoon acquired the eſteem both of Saumaiſe and Helvetius, who at this period were reſidents in that univerſity. In 1651 he was nominated profeſſor of the belles lettres at Geneva, and in the following year was admitted into the great council. His high reputation cauſed him ſoon after to be invited by the emperor to ſuperintend the education of his only ſon, and in this ſituation he applied himſelf to gain a thorough knowledge of the public law of Germany. Having obtained leave to travel into Italy, he was charged by his maſter to watch over the political intrigues of the Catholic electors at Rome ; and at the ſame time he made himſelf acquainted with the ſcience of medals and claſſical antiquity. While out on this tour he was introduced to the celebrated CHRISTINA (ſee her article), then reſiding at Rome, who favoured him with a gracious reception, and alſo to the ſtill more illuſtrious lady Sophia, electreſs of Hanover, who brought him back with her to Heidelberg in 1665. The elector-palatine, then engaged in various other projects, permitted Spanheim to enter into the ſervice of the elector of Brandenburg, for whom he reſided nine years in the quality of envoy-extraordinary. On his return to Berlin he was made one of the miniſters of the ſtate, and at the peace of Ryſwick, he was deputed again to France. The elector, being now acknowledged king of Pruſſia, conferred upon M. Spanheim the title of baron, and ſent him in the character of extraordinary miniſter to queen Anne of England. He was received at her court with all the reſpect and honour due to his merit, and was, on account of his talents, elected fellow of the Royal Society. He died in this country, at the age of 81. It is ſaid of this author, that he filled his diplomatic character as if he were entirely detached from letters, and his literary character as if he had no concern with politics. His erudition was ſolid and extenſive, of which he gave various proofs in his writings. The earlieſt of theſe were either theological or juridical; but he is beſt known as an antiquarian and critic. "His work," ſays his biographer, "entitled 'De Uſu et Preſtantia Numiſmatum Antiquorum,' in two volumes folio, is accounted one of the beſt treatiſes that ever appeared on the medallic ſcience." His tranſlation into French of the "Cæſars," of the emperor Julian, with illuſtrations; his edition of the ſame work, with a preface and notes; and his obſervations on Callimachus and other authors, with ſome diſſertations on ſubjects of antiquity in the collection of Grævius, are reckoned extremely valuable contributions to critical literature. The wife of this learned profeſſor, who died the year before him, was worthy to be his partner, from her extraordinary acquiſitions, being miſtreſs of various languages, and well acquainted with the philoſophy of the ancients.

SPANIARD's Bay, in *Geography*, a bay on the E. coaſt of the iſland of Cape Breton.—Alſo, a bay on the N. coaſt of the ſame iſland. N. lat. 46° 15′. W. long. 60° 20′.

SPANIEL, Hispaniolus, or *Canis Avicularius* of Linnæus, a variety of the *Canis familiaris*, a ſpecies of dog uſed in fowling. See Dog.

From the name, it may be ſuppoſed that we were indebted to Spain for this breed. There are two varieties of this kind; the firſt formerly uſed in hawking to ſpring the game, the ſame with our ſtarters; the others uſed only for the net, and formerly called *index*, or *ſetter*. This kingdom has been remarkable for producing dogs of this ſort, particular care having been taken to preſerve the breed in the utmoſt purity. They are diſtinguiſhed by the name of Engliſh ſpaniels; ſo that, notwithſtanding the derivation of the name, it is more than probable they are natives of Great-Britain.

The pointer, which is a dog of foreign extraction, was unknown to our anceſtors.

The aquaticus, or finder, in Dr. Caius's ſyſtematic arrangement (ſee Dog), was the ſame with our water ſpaniel, and uſed to find or recover the game that was loſt.

The ſpaniel is of great uſe, but ſubject to many diſtempers; among theſe the mange is a very frequent one, and is the moſt pernicious of all others to his quiet and his beauty; and is very apt, when one dog has it, to ſpread to others that come in its way. As a remedy for this diſeaſe, ſome have recommended a decoction of a large quantity of brimſtone, with ſome common ſalt and wood-aſhes, in water and urine, of each equal quantities: this is to be uſed three or four times a day, waſhing the creature well with it before the fire, or in the warm ſun. If this is not ſtrong enough, the ſame ingredients, with the addition of a conſiderable quantity of wood-ſoot, are to be boiled in ſtrong vinegar, and the liquor uſed in the ſame manner; but this muſt never be uſed in cold weather, as it would then endanger the creature's life.

When this diſeaſe is not in a violent degree, it may be cured by the herb agrimony internally taken. The method is to pound the roots, leaves, and ſeeds of this plant in a mortar, and mix them with a large quantity of wheaten-bran; they are to be then made into dough in the common way, and baked in an oven; the dog is to have no other bread but this for ſome time, but he is to eat of this as often and as much as he will: this, without any further care, has cured many. See *Diſeaſes of Dogs*, under Dog.

Another very troubleſome diſorder in this creature, is what is called the *formica:* this infeſts only the ears, and is cauſed by flies, and by the dog's ſcratching for them. The beſt medicine for the cure of theſe is this: take a quantity of pure and clean gum tragacanth, infuſe it in white-wine vinegar; let as much vinegar be uſed as will ſerve to ſoften it, and when it has lain a week in it, let it be taken out and ground on a marble, as the painters grind their colours, adding to it rock-alum and galls, reduced to powder, of each two ounces; all this is to be well mixed together, and the matter, if it grows too ſtiff in the grinding, is to be moiſtened with ſome of the vinegar in which the gum was ſoaked: when all is thoroughly mixed, and ground fine, it is to be put in a gallypot, and a ſmall quantity of it applied to the creature's ear every night, till the complaint is removed.

The ſwelling of the throat is another diſeaſe very common to ſpaniels, but the cure of this is eaſy; there needs only to bathe it well with oil of chamomile, and afterwards waſh it with a mixture of vinegar and ſalt; this done night and morning, will, in a few days, wholly remove the complaint. Spaniels will ſometimes, when they have much reſt and good food, loſe their ſenſe of ſmelling, but this is recovered by a briſk purge and repeated airings; a very common doſe, on this occaſion, is a drachm of jalap, and two drachms of ſal gem, mixed up into a bolus with oxymel of ſquills: this is to be rubbed over with ſome butter, and will be got down in that manner pretty eaſily, and will work briſkly.

Spaniel, *Gentle*. See Lap-dog.

SPANISH *Academy*, *Bible*, *Black*, *Brown*, *Coinage*, *Coins*, *Epocha*, *Inquiſition*, *Language*, *Meaſures*, *Order*, *Plough*, *Silk*, *Soap*, *Wax*, and *White*. See each article, and Spain.

Spanish, or *Liſbon*, *Bean*, in *Agriculture*, the common name of a particular ſort of bean, which is ſmaller than the long pod kind, but which ripens about the ſame time, and is very productive. See Bean.

Spanish *Broom*, in *Botany*. See Spartium.

Spanish *Cheſnut*, in *Planting*, a tree of the deciduous timber kind. See Chesnut-*Tree*.

This is a moſt valuable ſort of tree, as it affords, in a quick, ſpeedy, and abundant manner, the beſt ſort of hop-pole that has yet been met with, and which far ſurpaſſes that of the aſh, being conſiderably more durable.

Spanish *Elm*, in *Botany*. See Cordia.

Spanish *Flies*. See Cantharides.

Spanish *Juice*. See Liquorice.

Spanish *Potatoes*, in *Gardening*, the common name of a plant producing white, tuberous, eatable roots, ſomewhat like large kidney potatoes of the ſame colour, and of a ſweetiſh taſte. They are uſually brought here from Spain. See Convolvulus.

Spanish *Sheep*, in *Agriculture*, a breed of very fine ſhort-woolled ſheep, originally imported into this country from Spain. See Sheep.

Spanish *Windlaſs*. See Windlass.

Spanish *Wool*. See Sheep and Wool.

Spanish *Cove*, in *Geography*, a creek at the weſtern extremity of the county of Cork, Ireland, between Crookhaven and Mizen Point.

SPANISH *Creek*, a river of Florida, which runs into the river St. Mary.

SPANISH *Main*, that part of the Atlantic ocean which waſhes the N. part of South America, from the Leeward iſlands to the iſthmus of Darien. The term is alſo applied to the coaſt.

SPANISH *Point*, a cape on the N.E. coaſt of the iſland of St. Vincent. N. lat. 13° 24′. W. long. 61° 12′.

SPANISH *River*, a river and ſettlement on the iſland of Cape Breton.

SPANISH *Town*, or *St. Jago de la Vega*, a ſea-port town of Middleſex county, and capital of the iſland of Jamaica, ſituated on the banks of the river Cobre, about ſix miles from the ſea, and containing between 500 and 600 houſes, and about 5000 inhabitants, including free people of colour. It is the reſidence of the governor, or commander-in-chief, who is accommodated with a ſuperb palace; and here the legiſlature is convened, and the court of chancery and the ſupreme court of judicature are held. N. lat. 18° 1′. W. long. 76° 44′. See JAMAICA.

SPANISH *Town*, or *Virgin Gorda*, one of the Virgin iſlands in the Weſt Indies, called alſo Penniſton, belonging to the Engliſh, and having two good harbours. N. lat. 18° 20′. W. long. 63° 48′. See VIRGIN *Iſlands*.

SPANN, in *Commerce*, a corn-meaſure of Sweden; two ſpanns being equal to a *Tunna*; which ſee.

SPANNBERG, in *Geography*, a town of Auſtria; 5 miles S. of Ziſterzdorff.

SPANNER, in *Rural Economy*, the name of a wrench or nut ſcrew-driver, which is often very uſeful for the farmer.

SPAR, in *Mineralogy*, a name given by working miners in England to all cryſtallized minerals which have a ſhining luſtre: it is ſynonimous with *ſpath*, from the German.

The obſervation that ſpar is continually formed at this time in caves and grottoes under ground, has given birth to many different conjectures as to the origin of that ſubſtance. We have accounts from Switzerland, and other places, that the ſnow, by long lying on the earth, and being ſubject to repeated freezing, is at length hardened into ſpar: this is much of the nature of that opinion of the ancients concerning cryſtal, that it was water frozen by ſevere colds to a ſort of ice, much harder than the common kind: both are equally erroneous and abſurd. But more rational conjectures, as to its original, are, that it is produced either by effluvia alone, or by the joint force of effluvia iſſuing up from the depths of the earth, and mixing with water oozing out of rocks into their cracks and cavities, or by the ſame water or effluvia paſſing through beds of this ſparry matter contained in clay. In the firſt place, we are to obſerve, that ſpar is capable of being diſſolved either by water or vapour, and ſuſpended imperceptibly in either; and that though it remains ſuſpended a long time, yet there are occaſions of its ſeparating itſelf from either of theſe vehicles; ſuch are long ſtanding ſtill, and evaporation. What is called the growth and formation of ſpar, therefore, is properly perhaps only the change of place in this ſubſtance; and all that theſe agents, waters and vapours do, is only to waſh it out of the ſtrata of earth or ſtone, in which it lay in ſcattered particles, and bring it together into the cracks and crevices of ſtones, where it may again ſeparate itſelf, and become more pure and perfect.

The operation of nature, in this caſe, is very like that of art in extracting of ſalts from the various bodies they are mixed with; and ſpar, in its two ſtates, when blended in the ſtrata of ſtone, &c. and when pure, and in form of cryſtals in the cracks, may be compared to alum, for inſtance, in its bed, and when purified. The alum, in the common ſtones from which it is made, is not perceptible to the eye, but lies in ſcattered particles; water being added to this, takes up the ſalt, and when it has been managed by evaporation and reſt, yields it again purified and alone, and it forms ſuch cryſtals on the ſides of the veſſel as the other does on the ſides of the fiſſures of ſtone, which are the veſſels where the water, out of which it was formed, was ſet to evaporate, and to reſt a proper time.

That ſome ſpars grow from vapours alone is evident, from the ſtalactitæ, or ſtony icicles, hanging down from the roofs of our caverns, which, though they grow downwards, yet have many times little plants of the ſame ſubſtance growing out at their ſides, and ſtanding upwards, contrary to the growth of the other, and evidently formed of the matter ſeparated from the vapours in their aſcent, as the ſtalactitæ themſelves are from ſuch as have aſcended to the roof, and there been condenſed into water, and ſent down again in drops. Nor is the ſparry matter alone thus raiſed in vapour, for even the metals, and other bodies as little likely as thoſe to be thus raiſed, yet are found to form ſtalactitæ.

The mundics, in general, though they never form regular ſtalactitæ, yet often are found adhering to the ſides of them, and the metals, particularly iron and lead, form regular ſtalactitæ; the iron ones very common and very perfect; the lead leſs perfect and more rare; and Dr. Brown gives us abundant inſtances of ſpars growing entirely from vapours in the baths of Buda in Hungary.

Mr. Beaumont is of opinion, that earth by degrees will ripen into ſpar; but this is an error. He founds his opinion on certain ſtalactitæ, and ſtalagmitæ, found in caverns, partly earth, and partly ſpar, and ſuppoſes that the whole would in time become ſpar; but there is nothing in nature to warrant this conjecture. Phil. Tranſ. N° 129.

M. de Juſſieu has given us, in the Memoirs of the Paris Academy, a very remarkable account of the recryſtallization, or reproduction, of the parts of ſpar, after ſolution. Mem. Acad. Paris, 1719.

The denomination of ſpars, ſays the editor of the Chemical Dictionary, is given to many ſtones of different properties and appearances, which do not poſſeſs conſtantly any one common character or mark, by which they may be certainly diſtinguiſhed from other ſtones. In general, we may obſerve, that they are moſt frequently found in mines, and that they generally conſiſt of ſmooth and ſhining plates or laminæ; that ſome are tranſparent, and others opaque; that ſome are colourleſs and others coloured; that they are cryſtallized in various determinate figures, or poſſeſs no determinate ſhape; and, laſtly, that they differ ſo much in hardneſs, denſity, degree of fuſibility, and in their moſt eſſential chemical properties, that they cannot be conſidered as forming a diſtinct claſs of foſſile ſubſtances.

The ſeveral ſtones to which the name of ſpar has been given are, the calcareous, the gypſeous, the fluors, and feltſpar. Calcareous ſpars are ſoft heavy ſtones, which have the common chemical properties of calcareous earth. The texture is laminated, ſome of them have no determinate figure, and others from their form are called rhomboidal. Some ſpars, called dog's-tooth ſpars, have a pyramidal figure; but when theſe are broken, their fragments ſhew that they alſo conſiſt of rhomboidal particles. Some rhomboidal ſpars are tranſparent, others are opaque; ſome are colourleſs, and others are coloured; and ſome of them have a property of doubly refracting the rays of light: this ſpar has been called refracting ſpar, or iſland cryſtal. Its figure is that of an oblique parallelepiped, contained within ſix parallelogrammic ſides, and eight ſolid angles. Each of the obtuſe angles of the parallelograms is 101° 52′; and each of the acute angles is 78° 8′. Theſe calcareous ſpars may be diſtinguiſhed from others by effervescing with acids.

The gypſeous, or ſelenitic ſpars, are gypſeous earth, diſtinctly cryſtallized. The form of the cryſtals is rhomboidal. They are alſo called ſelenites and glacies Mariæ. Theſe ſpars ſometimes aſſume other forms, and are very heavy.

Mr. Margraaf has ſhewn, that under this claſs are to be comprehended thoſe white opaque ſpars, which by calcination with inflammable matters are capable of receiving a phoſphoric quality, ſimilar to that of the Bolognian ſtone, which he alſo ſhews is a gypſeous ſpar. For the ſpars called fluors, ſee Fluor.

The feltſpar, or *ſpatum ſcintillans*, differs from all the preceding, in being ſo hard as to be capable of ſtriking ignited ſparks from ſteel. For which reaſon it is referred by Cronſtedt to the ſiliceous claſs of earths, and by him called rhombic quartz, becauſe the particles of which it conſiſt ſeem to be parallelepipeds, each of which is contained within ſix rhomboidal ſides. Its colours are various, white, grey, and red.

Several other foſſile ſubſtances conſiſt of large plates, and are, therefore, ſaid to have a ſparry texture. Such are ſome kinds of talcs, of hornblende, of quartz, of amianthus, and ſome calciform ores of metals.

Spars, in *Medicine*, have from the earlieſt times been recommended in nephritic complaints. Some have uſed one kind, ſome another, as the lapis judaicus, the ſparry incruſtations of caverns, petrified oyſter-ſhells, and water in which large quantities of ſpar are ſuſtained. After all, the nephritic virtues of ſpar want ſufficient proof; ſome even ſuſpect its uſe to be more hurtful than beneficial. See Crystal.

SPARADRAP, Sparadrápum, in *Pharmacy*, &c. an ancient name for a kind of ſear-cloth; or a linen-cloth ſmeared on both ſides with ſome kind of plaſter, or unguent.

The ſparadrap is ſometimes alſo called *tela Gualteriana*, or *tela Gualteri*; ſometimes *tela emplaſtica*.

It is prepared by melting a ſufficient quantity of ſome plaſter or unguent, and dipping a linen-cloth therein, till ſuch time as it hath imbibed its fill. It is then taken out, cooled, and poliſhed on a marble.

SPARAGUS, or Asparagus, *Sperage*, in *Botany*. See Asparagus.

SPARAXIS, ſo named by Mr. Gawler, now Ker Bellenden, from σπαραξις, *a tearing*, or *plucking*, in alluſion to the torn appearance of the ſheath, which makes a principal part of the generic character.—Ker in Sims and Kon. Ann. of Bot. v. 1. 225. Ait. Hort. Kew. v. 1. 85.—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Enſatæ*, Linn. *Irides*, Juſſ.

Gen. Ch. *Cal.* Sheath inferior, of two membranous, dry, unequal, claſping valves, torn and ſhrivelled at the extremity. *Cor.* of one petal, ſuperior; tube funnel-ſhaped, ſlender at the baſe; limb dilated, in ſix ſegments, either regular or irregular, ſpreading or partly erect. *Stam.* Filaments three, inſerted into the upper part of the tube, thread-ſhaped, ſtraight, a little inclining, rarely aſcending, much ſhorter than the limb; anthers oblong, incumbent. *Piſt.* Germen triangular; ſtyle thread-ſhaped; ſtigmas three, ſpreading, recurved, oblong, downy. *Peric.* Capſule roundiſh-oblong, full of unequal ſwellings, thin, of three cells and three valves. *Seeds* numerous, globoſe.

Eſſ. Ch. Sheath of two valves, membranous, dry, jagged. Corolla tubular. Stigmas three, oblong, recurved. Capſule roundiſh-oblong, tumid.

Obſ. The character of this genus chiefly depends on its *ſheath*, which is large, and exhibits its diſtinctive marks, as above deſcribed, ſufficiently clearly. The limb of the *corolla* is either regular and ſpreading, or converging downwards, or two-lipped, with an erect hood; in which laſt caſe the *ſtamens* and *ſtyle* are upright, otherwiſe ſpreading, or inclining. The *bulb* is ſolid, ovate, pointed, clothed with reticulated ſcales. The *ſtem* moſt frequently bears axillary bulbous buds. *Leaves* from ſix to ten, ſword-ſhaped, with fine parallel ribs. *Flowers* rather large, and ſomewhat diſtant from each other; never crowded or numerous. *Ker.*

1. S. *anemoniflora.* Large White Sparaxis. Ker n. 1. (Ixia amemoniflora; Willd. Sp. Pl. v. 1. 200. Jacq. Ic. Rar. t. 273.)—Stem ſingle-flowered, as tall as the leaves. Corolla regular; its ſegments obovate, four times as long as the tube.—Native of the Cape of Good Hope. Cultivated by Jacquin. The *ſtem* is about a foot high, ſimple, oblique, with five or ſix *leaves* at the bottom only, which are linear and glaucous, the longeſt of them nearly equal to the ſtem. *Flower* two inches in diameter, pure white, with yellow anthers; its tube equal to the *ſheath*, which meaſures about a quarter of an inch.

2. S. *fragrans.* Sweet Yellow Sparaxis. Ker n. 2. (Ixia fragrans; Willd. Sp. Pl. v. 1. 197. Jacq. Ic. Rar. t. 274.)—Stem uſually two-flowered, ſhorter than the recurved leaves. Corolla regular; its ſegments elliptic-lanceolate, thrice as long as the tube.—Native of the Cape. Cultivated by Jacquin. *Stem* a ſpan high, leafy. *Leaves* linear, narrow, green, about twice the length of the ſtem, all more or leſs recurved. *Flowers* about half the ſize of the foregoing, yellow, with white many-cleft *ſheaths*.

3. S. *tricolor.* Three-coloured Sparaxis. Ker n. 3. Ait. n. 1. (Ixia tricolor; Curt. Mag. t. 381. Schneevogt. Ic. t. 39. Redout. Liliac. t. 129.)—Stem two or three-flowered, taller than the erect lanceolate leaves. Corolla regular; its ſegments obovate, twice the length of the tube. Sheath corrugated, ſpotted.—Native of the Cape, from whence it was introduced into the Dutch gardens, and thence into ours. It flowers, like the reſt of its family, in the frame or greenhouſe, about May. The *foliage* is green. *Flowers* peculiarly ſplendid, as large as the firſt ſpecies; their tube and baſe of the limb yellow; middle of the limb marked with an angular, or arrow-ſhaped, dark purple, or chocolate-coloured, ſpot; all beyond it of an orange ſcarlet. The *ſheaths* are wrinkled, furrowed, brown, copiouſly dotted with a darker tint.

4. S. *galeata.* Hooded Fleſh-coloured Sparaxis. Ker n. 4. (Gladiolus galeatus; Jacq. Coll. v. 4. 167. Ic. Rar. t. 258. Willd. Sp. Pl. v. 1. 212, excluding moſt of the ſynonyms.)—Corolla irregular; its upper ſegment ſpreading. Leaves elliptic-oblong.—Native of the Cape: cultivated by Jacquin. The *ſtem* is leafy, a ſpan high. *Leaves* equitant, vertical, broad, many-ribbed, and obtuſe. *Flowers* about three, fleſh-coloured or pale purpliſh; the lower lip yellow: the upper ſegment, or hood, is remarkably divaricated. Perhaps the irregularity of the *corolla* would rather authorize the referring this and the following, as moſt authors have done, to *Gladiolus*, near our fourth ſpecies of that genus. See Gladiolus.

5. S. *bicolor.* Purple and Yellow Sparaxis. Ker n. 5. Ait. n. 2. (Ixia bicolor; Ker in Curt. Mag. t. 348. Gladiolus bicolor; Thunb. Diſſ. n. 16. t. 2. f. 1. Willd. Sp. Pl. v. 1. 216. Jacq. Ic. Rar. t. 240.)—Corolla irregular; its ſegments converging. Leaves lanceolate.—From the ſame

country. Introduced at Kew in 1786, by Mr. Maſſon. The *leaves* are narrower, and more acute, than in the laſt. *Flowers* three or four, with ſpotted *ſheaths*; their tube, and two lateral ſegments, pale yellow, or whitiſh; hood purple; lip deep yellow.

6. S. *grandiflora*. Large-flowered Sparaxis. Ker n. 6. Ait. n. 2. (Ixia grandiflora; De la Roche Diſſ. 23. Curt. Mag. t. 541. Redout. Liliac. t. 139. I. ariſtata; Thunb. Diſſ. n. 15. Ait. ed. 1. v. 1. 57. Willd. Sp. Pl. v. 1. 203. Andr. Repoſ. t. 87. I. foliis gladiolatis, &c.; Mill. Ic. t. 237. f. 3. I. uniflora; Jacq. Ic. Rar. t. 283. I. holoſericea; Jacq. Hort. Schoenbr. v. 1. 9. t. 17.)

β. Curt. Mag. t. 779.

Corolla regular; its ſegments obovate-oblong, four times the length of the tube. Stamens and ſtyle inclining. Sheath with many awl-ſhaped ſegments. Leaves erect, lanceolate. —Native of the Cape. Long ſince cultivated in the gardens of Europe. The *ſtem* is about a foot high, bearing uſually three or four handſome *flowers*; ſometimes but one. *Leaves* equitant, ſcarcely glaucous, uſually much ſhorter than the ſtem. *Sheaths* ſtriated, ending in many lax taper ſegments, of their own length. *Corolla* full two inches wide; uſually of a rich deep ſatin-like purple, edged with white, and paler beneath; but in the variety β, it is whitiſh, or ſulphur-coloured, with ſome central ſpots, on the upper ſide; violet beneath. It muſt be allowed that authors have multiplied figures of this ſpecies in a moſt blameable manner.

7. S. *bulbifera*. Bulb-bearing Sparaxis. Ker n. 7. Ait. n. 4. (Ixia bulbifera; Linn. Sp. Pl. 51. Willd. Sp. Pl. v. 1. 204. Andr. Repoſ. t. 48. Curt. Mag. t. 545. Redout. Liliac. t. 128. Ixia foliis linearibus glabris, caule folioſo bulbifero; Mill. Ic. t. 236. f. 2.)—Corolla regular; its ſegments elliptical, acute, four times the length of the tube. Stamens inclining. Sheath deeply torn. Leaves erect, lanceolate. Stem bulbiferous, ſomewhat branched.—From the ſame country as the laſt, and known as long in our gardens. It is taller than that ſpecies, with paler *leaves*. The *ſtem* is generally branched and leafy, bearing a few bulbs at each joint, by which the plant may be increaſed. Each branch uſually bears two diſtant *flowers*, rather ſmaller than the foregoing, but with the ſame ſilky aſpect, though their colour is an uniform pale yellow, or white; and their ſegments are more acute.

8. S. *fimbriata*. Fringed Sparaxis. Ker n. 8. (Ixia fimbriata; Lamarck Dict. v. 3. 339. I. foliis gladiolatis nervoſis, &c.; Mill. Ic. t. 237. f. 1, 2.)—Corolla regular; its ſegments elliptical, obtuſe, four times as long as the tube. Stamens erect? Sheath deeply torn. Leaves erect, bluntiſh, about as tall as the ſimple, zigzag, three-flowered ſtem.—Native of the Cape of Good Hope. Cultivated by Miller. We adopt this ſpecies, (though omitted by Mr. Dryander in Ait. Hort. Kew.) on the authority of the authors quoted, for we have had no opportunity of inveſtigating it. Its humble growth, and the abruptneſs of the *leaves*, ſeem to indicate a ſpecific difference from the two laſt. The *ſtem* bears no bulbs, and is quite ſimple; leafy at the baſe only. *Flowers* large; white or yellowiſh above; tinged with violet beneath. Miller repreſents both *ſtyle* and *ſtamens* erect, but we dare not implicitly rely on this. The *ſheaths* are ſplit into numerous very long and ſlender ſegments.

Mr. Ker merely mentions an eighth ſpecies, under the name of *S. lacera*, ſeen by him in ſir Joſeph Banks's herbarium, with which we are unacquainted.

SPARENBERG, in *Geography*, a town and citadel of Weſtphalia, in the county of Ravenſberg; 2 miles S.E. of Bielefeld.

SPARGANIUM, in *Botany*, σπαργανιον of the Greeks, a very expreſſive ancient name, derived from σπαργανον, *a fillet*, or *bandage*, and alluding to the long flat linear form, and pliant texture, of the ribband-like foliage—Linn. Gen. 480. Schreb. 621. Willd. Sp. Pl. v. 4. 199. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 961. Ait. Hort. Kew. v. 5. 235. Brown Prodr. Nov. Holl. v. 1. 338. Purſh v. 1. 33. Juſſ. 26. Tourn. t. 302. Lamarck Illuſtr. t. 748. Leers Herborn. t. 13. f. 11. Gærtn. t. 19.—Claſs and order, *Monoecia Triandria*. Nat. Ord. *Calamariæ*, or rather *Piperitæ*, Linn. *Typhæ*, Juſſ.

Gen. Ch. Male flowers numerous, collected into a head. *Cal.* Perianth of three linear, coloured, erect, deciduous leaves. *Cor.* none. *Stam.* Filaments three, capillary, longer than the calyx; anthers oblong.

Female, *Cal.* as in the male. *Cor.* none. *Piſt.* Germen ovate, tapering into a ſhort awl-ſhaped ſtyle; ſtigma oblique, undivided, downy, channelled along the upper ſide, permanent, uſually ſimple, rarely double. *Peric.* Drupa dry, turbinate, pointed; angular at the baſe. *Seed.* Nut hard, oblong-ovate, angular, uſually ſolitary; occaſionally there are two.

Eſſ. Ch. Male, Calyx of three leaves. Corolla none. Female, Calyx of three leaves. Corolla none. Drupa dry, with a ſolitary nut.

1. S. *ramoſum*. Branched Bur-reed. Hudſ. 401. Fl. Brit. n. 1. Willd. n. 1. Purſh n. 1. Curt. Lond. faſc. 5. t. 66. Engl. Bot. t. 744. Bauh. Theatr. 228. Ger. Em. 45. (S. erectum; Linn. Sp. Pl. 1378.)—Leaves triangular at the baſe; concave at the ſides. Common flower-ſtalk branched. Stigma linear.—Common in ditches, and about the banks of ponds and rivers, throughout Europe; more rare, according to Mr. Purſh, in North America. It appears to be the σπαργανιον of Dioſcorides, being the only ſpecies Dr. Sibthorp obſerved in Greece. It is perennial, flowering in July and Auguſt. *Root* creeping. *Stem* erect, about a yard high, round, leafy, ſmooth, alternately branched at the top in a panicled manner. *Radical leaves* triangular at the baſe, with concave ſides; their upper part erect, ſword-ſhaped, ſmooth, much taller than the ſtem; *ſtem-leaves* gradually ſhorter, flat, claſping at their baſe. *Partial flower-ſtalks* racemoſe, many-flowered; zigzag in the lower part. *Heads* alternate, ſeſſile, globoſe; the lower ones female, brown; upper male, cloſer and more numerous, with yellow *anthers*. *Calyx-leaves* ſpatulate, brown. *Germen* of two cells. *Stigma* elongated, linear, uſually ſolitary; when there are two ſtigmas, there ſeem to be two ſeeds alſo. The *Sparganium* of Moriſon, ſect. 8. t. 13. f. 2, ſeems an *Aliſma* or *Sagittaria*.

2. S. *ſimplex*. Unbranched Upright Bur-reed. Hudſ. 401. Fl. Brit. n. 2. Willd. n. 2. Purſh n. 2. Curt. Lond. faſc. 5. t. 67. Engl. Bot. t. 745. (S. erectum β; Linn. Sp. Pl. 1378. S. n. 345.* Linn. Fl. Lapp. ed. 1. 271. ed. 2. 280. S. non ramoſum; Bauh. Theatr. 231. S. latifolium; Ger. Em. 45. S. alterum; Bauh. Hiſt. v. 2. 541. Lob. Ic. 80.)—Leaves triangular at the baſe; flat at the ſides. Common flower-ſtalk ſimple. Stigma linear.—Native of ponds throughout Europe, eſpecially on a gravelly ſoil, flowering in July and Auguſt. More frequent in North America, according to Mr. Purſh, than the *ramoſum*, from which Hudſon and Curtis firſt well diſtinguiſhed this ſpecies. It is a ſmaller plant, and never branched or panicled. The lowermoſt head of *flowers* is generally ſtalked; the reſt being ſeſſile. *Calyx* green, or whitiſh, not brown. *Stigma* elongated, moſtly ſimple.

3. S. *natans*. Floating Bur-reed. Linn. Sp. Pl. 1378. Willd. n. 3. Fl. Brit. n. 3. Purſh n. 3. Engl. Bot. t. 273. Fl. Dan. t. 260.—Leaves drooping, flat. Com-

mon flower-ſtalk ſimple. Stigma ovate, very ſhort. Head of male flowers nearly ſolitary.—Native of rivers, pools, and lakes, in Europe and North America, chiefly on a muddy or clay ſoil, flowering in July. The *root* is long, perennial, creeping widely. *Herb* floating, with long flat *leaves*, half the ſize of the laſt; the upper ones ſheathing. *Cluſter* of few heads of *flowers*, of which the top one only, with ſometimes a portion of the next, is male; the lowermoſt is ſtalked. The ſhort, broad, ovate, always ſolitary, *ſtigma* beſt diſtinguiſhes this from *S. ſimplex*. Willdenow perſiſts in citing the *Fl. Lapp.* for this, though he refers to it properly under the preceding, except that in both caſes he omits the aſteriſk.

4. S. *anguſtifolium*. Narrow-leaved Bur-reed. Br. n. 1. (S. anguſtifolium; Michaux Boreal-Amer. v. 2. 189? S. natans β; Purſh n. 3?)—“Leaves flat, lax, longer than the ſtem. Heads of male flowers numerous. Stigma oval. Drupa obovate, even; depreſſed at the ſummit.”—Found by Mr. Brown near Port Jackſon, New South Wales. If the ſynonyms be right, it is alſo a native of rivulets in Canada.

SPARGANOPHORUS, from σπαργανον, *a fillet*, and φερω, *to bear*, becauſe the ſeed is crowned with a membranous band, or border.—Vaill. Act. Pariſ. ann. 1719. Gærtn. v. 2. 395. t. 165. Michaux Boreal-Amer. v. 2. 95. Purſh v. 2. 518.—We have already ſpoken of the plant of Vaillant and Gærtner under ETHULIA, (ſee that article,) of which, in our opinion, it conſtitutes a genuine ſpecies. Perhaps that of Michaux and Purſh may belong to the ſame genus, but we dare not, without examination, aſſert this. The word *Sparganophorus*, though not exactly compounded of *Sparganium*, may be thought rather too near to that name, and we, on many accounts, prefer *Ethulia*.

SPARGANOSIS, from σπαργαω, *to ſwell*, in *Surgery*, an abſceſs of the breaſt; a milk-abſceſs.

SPARGUS, in *Ichthyology*, a name given by Gaza to the common ſparus, which he calls alſo *fluta*.

Artedi calls it the plain yellow ſparus, with an annular ſpot near the tail. See SPARUS.

SPARHAWK POINT, in *Geography*, a cape on the north coaſt of the mouth of the river Piſcataqua.

SPARKS's ISLAND, a ſmall iſland in the bay of Honduras, at the mouth of the river Roman. N. lat. 15° 54′. W. long. 86° 5′.

SPARLING, in *Ichthyology*. See SMELT.

SPARLING-*Fowl*, in *Ornithology*, a name given in ſome places, by the country people, to the female merganſer, called more uſually the *dundiver*.

SPARNECK, in *Geography*, a town of Germany, in the principality of Culmbach; 3 miles S.S.E. of Munchberg.

SPARRE, ERIC, in *Biography*, chancellor of Sweden, was born in 1550; but from this time we have no account of him till 1578, when he was appointed ſupreme judge of Weſtmanland and Dalecarlia; and in 1582 he became a ſenator, governor of theſe provinces, and vice-chancellor of the kingdom. In 1583 he was knighted by king James VI. of Scotland; and in 1587 he went as envoy to Poland, reſpecting the elevation of Sigiſmund to the Poliſh throne. Within about two years from this time he fell in diſgrace, was deprived of his employments, and thrown into priſon. He was likewiſe accuſed of high crimes againſt the ſovereign, John III. On this occaſion his letter of knighthood was taken from him by the king, and torn to pieces before his face. He was, however, pardoned, on the interceſſion of king Sigiſmund; but was again arraigned, in 1592, before a court at which the king himſelf preſided, on a charge of having promiſed the ceſſion of Eſthonia, in direct contradiction to the inſtructions which he had received, when envoy of Poland. He defended himſelf with great boldneſs againſt all his accuſers; which ſo incenſed the ſovereign, that he drew his ſword, exclaiming, that it was given him by God to puniſh traitors and breakers of their oath. Duke Charles brought forth other accuſations againſt him; but the court broke up, after coming to this concluſion, that Sparre, and the other ſenators who had been accuſed with him, were neither condemned nor acquitted. Sparre fell again under the duke's diſpleaſure, on account of a celebrated book which he wrote, entitled “Pro Lege, Rege, et Grege;” which ſeemed to be directed againſt the authority exerciſed by that prince. Having, however, taken an oath of fidelity to the duke, and made a ſolemn promiſe of obedience in writing, he was reſtored to his employments; and, as chancellor of the kingdom, ſubſcribed, in 1593, the reconciliation between him and Sigiſmund. Notwithſtanding this, he was afterwards delivered up to the duke, and ſuffered under the hands of the executioner, during the bloody ſcenes that took place at Linkoeping, in 1600; but he maintained his innocence to the laſt, and read a proteſt againſt thoſe who had doomed him to puniſhment. He was author of many books, beſides the one already referred to, “Pro Lege,” &c. among which are the following: “Account of the Coronation of king Sigiſmund at Upſal, February 19, 1594;” “Sententia Ordinum Regni Sueciæ in quoſdam de Collegio Senatorum,” &c.; “Adverſus Inſimulationes et Proteſtationes à Regis Sigiſmundi legato Polono, Oratione prolata, Defenſio.” Gen. Biog.

SPARRING, among *Cock-fighters*, is the fighting a cock with another to breathe him. In ſparring, they put hotts on their ſpurs, that they may not hurt one another.

To ſpar the cock, imports in general to breathe him, in order to embolden him to fight. See HOTTS.

SPARRMANNIA, in *Botany*, ſo named by the younger Linnæus, in honour of his diſtinguiſhed countryman, Andrew Sparrmann, or rather Sparrman, the friend and pupil of his father, and the companion of the voyage of the Forſters, round the world. This gentleman is well known in England by the account of his travels in ſouthern Africa, which diſplay great candour and love of truth, as well as the true ſpirit of Linnæan philoſophy and accuracy. He is, we believe, ſtill living in Sweden.—Linn. Suppl. 41. Schreb. 355. Willd. Sp. Pl. v. 2. 1160. Thunb. Nov. Gen. 88. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 298. Juſſ. 290. Lamarck Illuſtr. t. 468.—Claſs and order, *Polyandria Monogynia*. Nat. Ord. *Columniferæ*, Linn. *Tiliaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of four lanceolate, undivided, ſpreading, nearly equal, deciduous leaves. *Cor.* Petals four, equal, wedge-ſhaped, flat, undivided, twice the length of the calyx. Nectary? of ſeveral thread-ſhaped, tumid, corrugated, or toothed, bodies, more properly to be eſteemed imperfect filaments, or ſtamens, partly changed to petals. *Stam.* Filaments numerous, thread-ſhaped, inſerted into the receptacle, about half the length of the petals; anthers ovate, incumbent. *Piſt.* Germen ſuperior, roundiſh, hiſpid, with five angles; ſtyle thread-ſhaped, longer than the ſtamens; ſtigma in many minute ſegments. *Peric.* Capſule five-ſided, with five cells; its angles armed with long, ſtraight, rigid, ſpreading thorns, each tipped with a ſharp tranſparent point. *Seeds* two in each cell, oblong, ſmooth, keeled at one ſide.

Eſſ. Ch. Calyx of four leaves, deciduous. Petals four. Barren filaments numerous, toothed. Capſule of five cells, angular, armed with ſtraight pungent ſpines. Seeds two in each cell.

Obſ. Ventenat has juſtly remarked that the ſuppoſed nectaries are, as well as the perfect ſtamens, inſerted into the receptacle, and not, as Schreber after Thunberg aſſerts, into the germen, and that they are properly to be conſidered as imperfect ſtamens.

1. S. *africana*. African Sparrmannia. Linn. Suppl. 265. Willd. n. 1. Ait. n. 1. Retz. Obſ. faſc. 5. 25. t. 3, (but the ſynonym, habitat, and all that follows, belong to the preceding *Lagerſtromia*.) Curt. Mag. t. 516. Venten. Malmaiſ. t. 78.—Native of woods and thickets, on the ſides of hills, at the Cape of Good Hope, flowering from October to January. It was introduced at Kew, in 1790, by Mr. Maſſon, and makes a moſt elegant and ſplendid appearance in the collection of greenhouſe ſhrubs, in the ſpring, and early part of the ſummer. The whole plant is clothed with fine, ſilky, ſpreading hairs. *Stem* ſhrubby, erect, two to ſix feet high, with round, alternate, leafy *branches*. *Leaves* alternate, ſtalked, dependent, large, heart-ſhaped, pointed, crenate, ſlightly lobed, veiny, reſembling thoſe of ſome Mallow, *Sida*, or *Hibiſcus*. *Stipulas* awl-ſhaped, lateral, in pairs near the baſe of each *footſtalk*. *Flowers* in large, terminal, hairy umbels, like thoſe of a Cape Geranium, with awl-ſhaped *bracteas*. *Calyx* downy, pale brown, not quite an inch long. *Petals* white, wrinkled, often emarginate. *Filaments* yellow, partly crimſon. *Anthers* brown. This ſhrub is propagated, without much difficulty, either by cuttings or ſeeds; but we know not whether the latter are often perfected in Europe.

SPARROW, Passer, in *Ornithology*, the name of a large order of birds. See Passeres.

Sparrow, *Common*, or *Houſe*, the *Fringilla domeſtica* of Linnæus, is a well-known bird, and needs no deſcription. Sparrows are proverbially ſalacious: they breed early in the ſpring, often in the neſts of the martin, after expelling the owner; the martin, however, in revenge, is ſaid to aſſemble its companions, and to aſſiſt in plaſtering up the entrance with dirt, and thus leaves the invader to periſh. See Fringilla.

Sparrow, *Hedge*, *Curruca*, or *Motacilla modularis* of Linnæus, a bird of the ſize of the red-breaſt, or of the titlark. Its beak is longiſh, ſlender, and black; its head is of a deep brown, mixed with aſh-colour; the cheeks are marked with oblong ſpots of dirty white; the back and coverts of the wings are duſky, edged with reddiſh-brown; the quill-feathers and tail duſky; the rump brown, tinged with green; the throat and breaſt are of a dull aſh-colour; the belly of a dirty white; the ſides, thighs, and vent-feathers are of a pale tawny brown; and the legs of a dull fleſh-colour. This bird frequents low hedges, particularly thoſe of gardens; making its neſt in ſome ſmall buſh, where it lays four or five eggs of a fine pale blue colour; and during the breeding-ſeaſon it has a remarkable flirt with its wings. The male has a ſhort but very ſweet plaintive note, which it begins with the firſt froſty mornings, and continues till a little time in the ſpring.

The bird which Linnæus ſuppoſes to be our hedge-ſparrow, which he deſcribes under the title of *motacilla curruca*, and to which he applies the denomination of *cannavarola*, differs in colour of plumage as well as eggs. Pennant.

It is in the neſt of this bird that the cuckoo hatches her eggs for the moſt part, though not always, the neſts of turtle and wood-pigeons being ſometimes uſed by her for that purpoſe. Hence it was that the ancients made the cuckoo an emblem of ſuch men as made bold with the marriage-bed of others, who, on that account, were called *curruca*. See Motacilla.

Sparrow, *Reed*, *Paſſer arundinaceus*, the *Emberiza ſchoeniclus* of Linnæus, a bird that lives moſt commonly among reeds in marſhy places, and known among authors by the name of *junco*.

Its neſt is curiouſly contrived, being faſtened to four reeds, and ſuſpended by them like a hammock, about three feet above the water. It lays four or five eggs of a blueiſh-white, marked with irregular purpliſh veins. This bird is much admired for its ſong, and like the nightingale it ſings in the night. In the male, the head, chin, and throat, are black; the tongue livid; at each corner of the mouth commences a white ring, which encircles the head; at approach of winter the head changes to hoary, but on return of ſpring reſumes its jet colour; the whole under ſide of the body is white; the back, coverts of the wings, and the ſcapular feathers, are black, deeply bordered with red; the two middle feathers of the tail are of the ſame colours, the three next black; the exterior web, and part of the interior of the outmoſt feather, are white: the head of the female is ruſt-coloured, ſpotted with black; it wants the white ring round the neck, but in moſt other reſpects reſembles the male. Pennant. See Emberiza.

Sparrow, *Leſſer Reed*, *Willow Lark*, or *Sedge-bird*, *Paſſer arundinaceus minor*, the *Motacilla ſalicaria* of Linnæus, is a ſpecies of a ſlender elegant form; the head brown, marked with duſky ſtreaks; over each eye a line of pure white, over that another of black; cheeks brown; throat, breaſt, and belly white, the two laſt tinged with yellow; hind-part of the neck and back of a reddiſh-brown; the back ſpotted with black; coverts of the tail tawny; coverts of the wings duſky, edged with pale brown; quill-feathers duſky; tail brown, and in the form of a wedge, and making a circle when ſpread, and legs duſky. This bird is common in low wet grounds, ſits on the top of ſome ſpray with its wings diſhevelled; its ſong conſiſts of but two notes, which are loud, querulous, and harſh. Pennant.

Ray obſerves, that the leſſer reed ſparrow ſings ſweetly, and ſome have called it *cannavarola*. See Motacilla.

Sparrow, *Solitary*. See Passer *Solitarius*.

Sparrow, *Tree*, *Paſſer montanus*, the *Fringilla montana* of Linnæus, is inferior in ſize to the common ſparrow; the bill is thick and black; the crown of the head, hind part of the neck, and leſſer coverts of the wings, are of a bright bay, the two firſt plain, the laſt ſpotted with black; the chin black; the cheeks and ſides of the head white, marked with a great black ſpot beneath each ear; the breaſt and belly of a dirty white; juſt above the greater coverts is a row of feathers, black edged with white; the greater coverts are black, edged with a ruſt-colour; the quill-feathers duſky, edged with pale red; lower part of the back of an olive-brown; the tail brown, and legs of a ſtraw-colour.

Theſe birds are common in Lincolnſhire, among trees, and collect, like the common kind, in great flocks. Pennant. See Fringilla.

Sparrow, *Water*, *Paſſer aquaticus*, a bird deſcribed by Nieremberg, which, he ſays, the Indians call *acototlequichitl*. It ſings all day long without ceaſing, but with no very pleaſing note. It is, however, a well-taſted bird. It lives among ſedge and buſhes, and is of the ſize and ſhape of a ſwallow, but has a black bill and yellow legs; its breaſt and belly are white, and its back is of a browniſh-yellow, variegated with ſpots of black and white. This bird much reſembles our reed ſparrow. Ray.

Sparrow, in *Agriculture*, a miſchievous deſtructive bird in corn-fields, and which ſhould moſtly be deſtroyed. It is obſerved, that were all the farmers in a neighbourhood to agree to their deſtruction, by offering rewards for their heads, their numbers might be leſſened; and that were the practice general, ſurely the whole race might be extirpated. It is ſuppoſed, that ſixpence a dozen the firſt year, nine-pence the ſecond, and a ſhilling the third year, would nearly reach their complete extirpation. To enforce which, it ſhould be conſidered how ſoon twelve ſparrows deſtroy twelve penny-worth of wheat.

In Kent, they uſe a ſpecies of trap, which is very effectual in taking them. It, according to Mr. Marſhall, conſiſts of a ſmall wicker baſket, reſembling the fruit-ſieve of the London markets, with a cover of the ſame material fitted to it, and formed on the principle of the fiſh-pot, and the vermin trap, into which the entrance is eaſy, but the return difficult. Theſe traps, which are an ordinary article of ſale in the markets of the diſtrict, are conſtituted of brown unpeeled oſiers. The diameter about two feet; the depth nine inches; the cover is ſomewhat diſhing, with a tunnel, or inverted cone, in the centre, reaching to within an inch of the bottom of the baſket; the aperture or entrance, formed by the points of the twigs, of which the tunnel is conſtructed, being about an inch and a half in diameter. And the uſual bait is wheat ſcattered in the baſket. The number caught at once, is frequently more than theory would ſuggeſt; the contentions of a few that have entered, ſeldom failing to bring others to the combat.

Theſe miſchievous birds, however, ſoon grow too cunning to be taken in any ſort of trap to any extent, which has a chance of extirpating and deſtroying the race; conſequently ſome more effectual and certain plan, ſuch as that ſuggeſted above, or ſome other, which is better and more fully adapted to the purpoſe, muſt be had recourſe to in order to completely exterminate them, and prevent the injury they do annually to the farmer, in the deſtruction of his wheat and other crops. Though theſe are only ſmall birds, they deſtroy vaſt quantities of grain, much more than has indeed been commonly ſuppoſed. It is ſtated to have been calculated to have amounted to a hundred ſacks of wheat, beſides the oats and barley, in the courſe of only one ſeaſon, in a townſhip of no very great extent in the north-weſtern part of the kingdom. Where rewards or ſums of money are paid for the taking or deſtroying them, no advantages are gained, except where there are ſufficiently ample and proper regulations entered into and enforced, the whole diſtrict, pariſh, or townſhip becoming partakers in the buſineſs. No languid or half meaſures will do any thing uſeful, or to the purpoſe, in this ſort of undertaking.

It is not improbable, but that theſe deſtructive birds might be greatly extirpated and thinned down in their numbers, by the uſe of ſome taſteleſs infuſion of a ſtrongly poiſonous nature, either to the ears of the grain at the time of harveſt, or to the naked grain in the winter ſeaſon, when they are extremely eager for food, as they are conſtantly found to remain hovering about houſes or other buildings, where the effects of ſuch trials might eaſily be aſcertained. If ſuch a method ſhould ſucceed, the whole race might readily, and with great facility and certainty, be exterminated.

SPARROW-*Graſs*, in *Botany*. See ASPARAGUS.

SPARROW-*Hawk*. See HAWK.

SPARROW-*Wort*, in *Botany*. See PASSERINA.

SPARRY, in *Mineralogy*, having a confuſed cryſtalline ſtructure, ſynonimous with ſpathoſe.

SPARRY *Iron Ore*, denominated alſo *brown ſpar* and *pearl ſpar*, is a mineral compoſed of the oxyd of iron combined with about thirty-five *per cent.* of carbonic acid, and a variable portion of manganeſe, lime, and magneſia. (See *Iron* ORES.) As pearl ſpar, this mineral may be claſſed among the earthy minerals. It has a white colour, paſſing by various gradations into brown, with a pearly luſtre; in the pure white ſpecimens the luſtre is brilliant. It occurs in ſmall curved rhomboidal cryſtals, which do not melt before the blow-pipe, but diſſolve with effervеſcence in muriatic acid. This mineral is generally found in veins, accompanying metallic ores, but is never worked as an ore of iron.

SPARS, in *Rural Economy*, a name often applied to thatching rods, or the ſpelks or rods by which thatch is bound on the roofs of buildings.

SPARS, in *Ship-Building*, ſmall fir-trees; called cant, which are from 33 to 35 feet long, and five hands circumference; barling, from 30 to 28 feet long, and four hands circumference; boom, from 24 to 20 feet long, and three hands circumference; middling, from 20 to 16 feet long; and ſmall, from 16 to 11 feet long.

SPARSE-LEAVES, *Sparſa folia*, among *Botaniſts*. See LEAF.

SPARTA, in *Ancient Geography*, a celebrated city of Greece, in the Peloponneſus, and the capital of Laconia. It was ſituated at the foot of mount Thornax, on the banks of the Eurotas, and to the W. of it.

According to Strabo, this city was founded by Patrocles; but the moſt common opinion attributes its origin to Leles, in the year 1516 B.C. Some maintain that it originated at Lacedæmon in the year 400 B.C. However this may be, it was known alſo by this name. However, the appellation of Spartans is applied to the inhabitants of Sparta and its territory, and that of Lacedæmonians to the inhabitants of the whole country of Laconia. (See LACONIA, and LACEDÆMONIANS.) This country was not equal in extent to Athens, containing only 48 ſtadia; but it was adorned in a very eminent degree. At firſt it had no walls, the Spartans confiding in their own valour for its defence. In proceſs of time, however, they conſtructed walls about it, when the ambition of Caſſander, and the violent aſſaults of ſome tyrants, had wearied out and almoſt exhauſted their fortitude. Pauſanias ſays, that it was fortified on occaſion of the wars of Demetrius and Pyrrhus, and he mentions in terms of high commendation ſome pieces of ſculpture, for which this city was diſtinguiſhed. Sparta was famous for a variety of public inſtitutions, among which were the ſenate of the aged, the ſenate of the conſervators of the laws, the ſenate of the ephori, and that of the magiſtrates, denominated Bidiæans. The firſt of theſe was the ſovereign tribunal of the Lacedæmonians, which regulated the affairs of the ſtate; the other ſenators were, properly ſpeaking, archons; the ephori were five, and the Bidiæans of the ſame number, whoſe province it was to direct and ſuperintend the exerciſes of the youth. The public edifices, temples, ſtatues, and monuments of Sparta, were ſo numerous and various, that we ſhould far exceed our limits in recounting them. It is not certain at what time this celebrated place was deſtroyed; but it was ſucceeded by the modern town of Miſitra, which is ſituated about four miles from ancient Sparta.

SPARTA was alſo the name of a town ſituated in the environs of the Euxine ſea. Steph. Byz.

SPARTA, in *Geography*, a poſt-town of America, in Sparta county, North Carolina; 541 miles from Waſhington.—Alſo, a poſt-town of New Jerſey, in Suſſex county; 117 miles from Philadelphia.—Alſo, a poſt-town of Hancock county, Georgia, with a court-houſe and gaol, ſituated in a fertile and populous country, and a place of conſiderable trade.

SPARTA, a poſt-townſhip of New York, in the S.W. corner of Ontario county, 25 miles S.W. of Conondaigua; bounded N. by Geneſeo and Livonia, E. by Livonia and Naples, S. by Steuben and Allegany counties, and W. by Geneſee county. It compriſes three townſhips. The alluvial lands are fine, and the territory is in general good and well ſettled, principally by emigrants from Pennſylvania. Hemp is raiſed in conſiderable quantities. In 1810 the whole population was 1397, with 65 ſenatorial electors; and the houſehold looms, of which there are 56, produced 17,772 yards of cloth. The whole number of families is 232.

SPARTACUS, in *Biography*, one of the ſcourges of Roman tyranny and cruelty, a native of Thrace, was born of very low parents, entered the army, then became a deſerter, and a robber. Being taken, he was confined as a gladiator in a receptacle at Capua for thoſe unfortunate men whoſe lives were devoted to the pleaſure of the Roman people. He eſcaped the horrid den, and placing himſelf at the head of a body of gladiators and fugitive ſlaves, he took a fortified place in the year B.C. 72, whence he made predatory excurſions throughout Campania. His force daily increaſed, and he defeated ſeveral commanders who were ſent againſt him. He marched into Ciſalpine Gaul, in order to give the ſlaves in his army, who mere moſtly Thracians and Gauls, an opportunity of returning home. Part of them, however, greedy of pillage, ſeparated themſelves from their commander, and were cut to pieces. The conſul Lentulus, upon this ſucceſs, which was extremely partial, purſued Spartacus, who turned about and gave him a total defeat; and then, in his turn, becoming the aggreſſor, he marched againſt the other conſul, Gellius, drove him from the field, and obliged him to take ſhelter in the walled towns. He retaliated the cruelty of the Romans towards the gladiators, by obliging a number of his captives to fight with each other round the funeral pyre of one of his commanders. He was now at the head of 120,000 men, and with theſe he ravaged moſt of the provinces of Italia, and ſtruck ſuch a terror at Rome, that Craſſus, at that time the man of the greateſt conſequence in the city, was ſent againſt him. He ſoon confined Spartacus in Lucania, and cut off ſome of his detachments, ſo that he would gladly have croſſed over to Sicily, but being prevented, he took poſt in a peninſula near Rhegium, where Craſſus encloſed him by a rampart drawn from ſea to ſea. Spartacus, however, found means to break through this barrier, and gain the open country, but he was here deſerted by a large body of his followers, who became the victims of Craſſus. Spartacus now retreated towards the mountains, and repulſed with loſs ſome of his purſuers. This ſucceſs was, however, his ruin; for his men inſiſted upon his return to give battle to Craſſus in the open field. Before the commencement of the engagement, Spartacus ſtabbed his horſe, exclaiming, "If I am victorious, I can eaſily get another; if vanquiſhed, I ſhall not want any." After a long conteſt, the Roman diſcipline prevailed. Spartacus, during extraordinary exertions of valour, was ſurrounded, and fell pierced with a multitude of wounds. He was unqueſtionably a brave man, and ſomething more than a courageous barbarian. He had, ſays Plutarch, not only ſtrength and elevation of mind, but a diſcernment and civility much ſuperior to his fortune. It is ſaid that his wife accompanied him into the field, pretended to the gift of prophecy, and probably inſpired him with a fanatical confidence in victory.

SPARTANBURG, in *Geography*, a diſtrict of South Carolina, containing 12,122 inhabitants, of whom 147 are ſlaves.

SPARTEL, CAPE, a cape of Morocco, W. of Tangier, being a headland, which divides the ſtraits from the Weſtern ocean. After doubling this cape, at the diſtance of 15 miles ſtands the little town of *Arzilla*; which ſee.

SPARTIANUS, ÆLIUS, in *Biography*, a Latin hiſtorian, flouriſhed in the time of Diocletian, to whom he dedicated the lives of Adrian, Ælius, Verus, Didius Julianus, Severus, and Peſcennius Niger, which, as well as his lives of Caracalla and Geta, are come down to our times. He is one of the writers of the "Hiſtoriæ Auguſtæ Scriptores," but his merits are not very great.

SPARTINA, in *Botany*, a name borrowed from *Spartum*, a kind of broom, or of hard graſs, both uſed in ancient as well as modern times, to make baſkets, cordage, &c.—Schreb. Gen. 43.—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume ſingle-flowered, compreſſed, of two boat-like, compreſſed, keeled, converging valves; the innermoſt longeſt; the broader one ſtriated at the back, and pointed. *Cor.* ſhorter than the inner valve of the calyx, of two nearly equal, linear, compreſſed, bluntiſh valves, claſping each other, the inner one rather the longeſt. Nectary none. *Stam.* Filaments three, capillary, very ſhort; anthers linear, ſquare, ſharpiſh, cloven at the baſe. *Piſt.* Germen ſuperior, linear, acute; ſtyle thread-ſhaped, erect, longer than the ſtamens; ſtigmas two, villous. *Peric.* none, except the calyx, which enfolds the ſeed, and at length drops it. *Seed* oblong, compreſſed.

This is all the account we have found of the preſent genus, of which its author has left nothing concerning the ſpecies, whether one or more, nor its native country. Theſe points can only be aſcertained from his herbarium; and as yet *Spartina* has not been adopted by any writer that has fallen in our way, though it ſeems to have the ſanction of Schrader in his *Flora Germanica*, v. 1. 169. That author, ſo learned in graſſes, ſtrongly objects to Roth's having referred to *Spartina* by the name of *phleoides*, the *Crypſis ſchænoides* of Schrader, Lamarck, and others; as being, he ſays, widely different, both in habit and the ſtructure of its flowers. *Spartina* however does not find a place in his *Flora Germanica*, and is, therefore, perhaps not of European growth.

SPARTIUM, *σπαρτιον* of Dioſcorides, ſo called from *σπαρτη*, *a rope*, becauſe of the uſe of the long, ſlender, tough branches, or bark, in making cordage.—Linn. Gen. 368. Schreb. 487. Willd. Sp. Pl. v. 3. 926. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 254. Sm. Fl. Brit. 753. Prodr. Fl. Græc. Sibth. v. 2. 53. Gærtn. t. 153. (Geniſta; Juſſ. 353. Tourn. t. 411. Lamarck Illuſtr. t. 619. f. 1.)—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, ſomewhat heart-ſhaped; its margin at the upper ſide very ſhort; at the lower furniſhed with five little teeth towards the extremity; coloured, ſmall. *Cor.* papilionaceous, of five petals; ſtandard inverſely heart-ſhaped, very large, entirely reflexed; wings ovate-oblong, ſhorter than the ſtandard, attached to the filaments; keel of two petals, lanceolate-oblong, longer than the wings, inſerted into the filaments, the lower edges of its petals connected by fine hairs. *Stam.* Filaments ten, combined all together at the baſe, adhering to the germen, unequal, gradually longer; the upper one very ſhort, the remaining nine in one ſet; anthers rather oblong. *Piſt.* Germen oblong, or roundiſh; ſtyle awl-ſhaped, aſcending; ſtigma united to the upper ſide of its ſummit, oblong, villous. *Peric.* Legume cylindrical, long, obtuſe, of one cell and two valves. *Seeds* ſeveral, kidney-ſhaped, ſomewhat globoſe.

Eſſ. Ch. Stigma longitudinal, villous above. Filaments monadelphous, adhering to the germen. Calyx extended downward.

The Linnæan genus of *Spartium* is, by Juſſieu, ſunk, partly in *Geniſta*, after Tournefort, and partly in *Cytiſus*. The ſpecies in the fourteenth edition of *Syſt. Veg.* are ſixteen; Willdenow has twenty-five; three of the Linnæan ones being referred to Thunberg's *Lebeckia*. They are all ſhrubby, with yellow, rarely white, ſtill more rarely purpliſh, *flowers*, and either ſimple or ternate *leaves*. One only is a native of Britain, though all the reſt are of European growth; ſixteen are enumerated amongſt our garden plants by Mr. Aiton; ſome of them bearing the open air, others requiring the ſhelter of a greenhouſe; but none of them very tender. As ſome of the others promiſe to be well worthy the notice of cultivators, and are eaſily propagated, we ſhall take a brief view of the whole, introducing one nondeſcript ſpecies, and offering a few corrections reſpecting ſome of the reſt.

Section 1. *Leaves ſimple.*

1. S. *junceum.* Spaniſh Broom. Linn. Sp. Pl. 995. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 85. Sm. Fl. Græc. Sibth. t. 671, unpubliſhed. (S. macrolobium; Renealm. Spec. 34. t. 35. Geniſta hiſpanica; Ger. Em. 1313. Geniſta; Matth. Valgr. v. 2. 574.)—Branches oppoſite, round, flowering at the extremity. Leaves lanceolate. Legume linear.—Native of the ſouth of Europe. Frequent, according to Dr. Sibthorp, on dry hills throughout Greece and the Archipelago, where it is known by the name of *σπάρτο*, being unqueſtionably the *σπαρτιον* of Dioſcorides. This ſhrub was one of the firſt exotics introduced into cultivation in England, where it is quite hardy, flowering moſt part of the ſummer, and much eſteemed for the beauty, and ſweet luſcious ſcent, of its large yellow bloſſoms. Its height is uſually ſix feet or more, and the copious, long, twiggy, tough *branches*, bearing a few elliptic-oblong *leaves*, make a ſingular appearance. The *flowers* are ſometimes double, but are not improved in beauty by that change.

2. S. *aphyllum.* Leafleſs Siberian Broom. Linn. Suppl. 320. Willd. n. 2. Pallas Voyage, v. 3. append. 742. t. V. f. 2.—Branches round, ſtraight, wand-like, ſmooth, ſubtended by very ſhort, linear-lanceolate, cloſe-preſſed, withering leaves. Petals all ſmooth. Legume ovate, with two ſeeds.—Found by Pallas in blowing ſand of the deſarts about the river Wolga, flowering in June. The *ſtems*, though ſhrubby and often ſix feet high, die down every year. They are ſlender and much branched, with a ſmall, inconſpicuous *leaf* under each branch. *Flowers* ſcattered along the ultimate branches, ſolitary, on ſhort ſtalks, ſmall, dull violet; yellowiſh at the baſe. *Legume* a quarter of an inch long, gibbous, compreſſed, ſilky, as well as the *calyx*, *flower-ſtalks*, and young *branches*.

3. S. *monoſpermum.* White ſingle-ſeeded Broom. Linn. Sp. Pl. 995. Willd. n. 3. Ait. n. 2. Curt. Mag. t. 683. (Pſeudo-ſpartum album aphyllum; Ger. Em. 1318.)—Branches round, furrowed. Cluſters lateral, of a few rather crowded flowers. Seeds ſolitary. Leaves lanceolate, ſilky, as well as the wings and keel.—Native of dry barren hills in Spain, Portugal, and Morocco. A hardy greenhouſe plant with us, flowering in June and July. The *ſtem* is five or ſix feet high, with numerous ſlender, pliant, glaucous, furrowed *branches*, bearing, while young only, a few ſimple, linear-lanceolate, obtuſe, ſilky *leaves*. *Flowers* in ſhort, lateral, denſe cluſters, white, with a dark-red ſmooth *calyx*. The *ſtandard* is ſtreaked minutely with crimſon, and ſilky at the back, about half an inch long. *Wings* and *keel* partly, but denſely, ſilky. *Seed* ſolitary.

4. S. *ſphærocarpum.* Yellow ſingle-ſeeded Broom. Linn. Mant. 571. Willd. n. 4. Ait. n. 3. (S. hypoſphærolobium; Renealm. Spec. 35. t. 33. Pſeudo-ſpartum hiſpanicum aphyllum; Ger. Em. 1318.)—Branches round, furrowed. Cluſters lateral, many-flowered, ſolitary or in pairs. Seeds ſolitary. Leaves lanceolate, downy beneath. Wings ſmooth. Keel ſomewhat ſilky.—Native of the ſouth of Europe. A greenhouſe plant, cultivated in Miller's time, flowering in June and July. Of more humble growth than the preceding, with more erect, ſtraighter *branches*, and yellow *flowers*, not half ſo large, though more numerous in each cluſter. Though the two plants are very diſtinct, their ſpecific definition is not eaſy. We agree with Mr. Curtis, as to the probability of Cluſius's wooden cuts, and conſequently thoſe of Gerarde above cited, (which are the ſame blocks as thoſe of Cluſius,) being tranſpoſed. Yet we cannot ſay they are ſo, for though the *infloreſcence* of Gerard's f. 1, applied to this yellow ſpecies, is more like the former, and *vice verſa*; the ſize of the *flowers* in f. 2 is too large for the preſent.

5. S. *triſpermum.* Yellow Three-ſeeded Broom.—Branches round, ſtriated, racemoſe. Leaves very ſhort, ſpinous-pointed. Wings ſmooth. Keel ſilky. Legume half-ovate, with three ſeeds.—Gathered on mount Ætna, by the baron Bivona, from whom we, laſt year, received ſpecimens. This is allied to the two laſt, though eſſentially diſtinct in its *fruit*, which more reſembles that of *S. aphyllum*, n. 3, but is nearly ſmooth, not ſilky, and contains three roundiſh *ſeeds*. The *flowers*, moreover, are diſpoſed as in that ſpecies, being looſely ſcattered along the young *branches*, not compoſing lateral cluſters: but they are thrice as large, yellow, and fragrant, with more oblong *petals*, and the *keel* is ſilky, in which laſt character this ſpecies agrees with *ſphærocarpum*. We have not ſeen the young *leaves*, but thoſe under the flowering branches are ſmall, thick, ſhort, furrowed, with a ſtrong ſharp point.—The figure of *Spartium*, Matth. Valgr. v. 2. 573, anſwers well to our plant, except that the *flowers* are repreſented much too ſhort, and the *legumes* too hairy, in which latter circumſtance it anſwers better to *S. purgans*, though, in other reſpects, not like that ſpecies; ſtill leſs does it reſemble the following.

6. S. *cinereum.* Grey-branched Broom. "Villars Proſpect. 40." Willd. n. 5. (Geniſta ſcoparia; Villars Dauph. v. 3. 420. Bellardi Append. ad Fl. Pedem. 34.)—Branches round, with ten furrows. Leaves lanceolate; ſilky beneath. Flowers axillary, ſolitary; their ſtalks not longer than the calyx. Keel ſilky. Legume hairy.—Native of ſunny hills in the ſouth of France and in Piedmont. The *branches* are much more leafy than in any of the foregoing. *Leaves* nearly ſeſſile, about three quarters of an inch long; ſmooth above. *Flowers* yellow, much longer than the leaves, on ſhort ſilky ſtalks. The *calyx* alſo is ſilky, deeply divided. *Keel* ſilky, eſpecially toward the lower edge. *Legume* hairy, with from three to five *ſeeds*. Gerard, from whom, as well as from Bellardi, we have ſpecimens, miſtook this plant, as many others have done, for *S. purgans*; but Willdenow well remarks, that the more erect and ſtraight *branches*, and eſpecially the ſhortneſs of the *flower-ſtalks*, diſtinguiſh it from that ſpecies. Villars thinks it may have been confounded with *S. ſcoparium*, which ſeems hardly poſſible. He conceives the figure of Matthiolus, Valgriſian edition, v. 2. 573, badly copied in Bauhin's Matthiolus, 852,

f. 1, may have been done for this plant; but it more reſembles our *triſpermum*.

7. S. *virgatum*. Long-twig'd Broom. Ait. n. 4. Willd. n. 6. (Cytiſus tener; Jacq. Coll. v. 1. 40. Ic. Rar. t. 147. Linn. Syſt. Veg. ed. 14. 667.)—Branches round, furrowed. Leaves obovate, rather ſilky. Flowers axillary, ſolitary, ſomewhat racemoſe. Petals all ſilky. Legume denſely hairy.—Found by Mr. Maſſon in Madeira, whence it came to Kew garden in 1777. It is a greenhouſe ſhrub, flowering in ſpring. The copious ſlender *branches* bear numerous alternate *leaves*, half an inch long. The *flowers* are yellow, very ſilky in every part, and form *cluſters* at the end of each branch, two or three of the lower ones only being axillary. *Legumes* lanceolate, pointed, clothed with ſhort denſe hairs, and containing three or four round *ſeeds*, which are ſeldom all perfected.

8. S. *ramoſiſſimum*. Branching African Broom. Desfont. Atlant. v. 2. 132. t. 178. Willd. n. 7.—Branches round, furrowed, ſtraight. Leaves obovato-lanceolate, villous. Flowers axillary, on ſhort ſtalks, ſomewhat whorled. Petals all ſilky.—Native of mount Atlas, near Tlemſen. A ſhrub, two or three feet high, leafleſs when old, flowering early in the ſpring. The *flowers* are yellow, erect. *Legume* not obſerved, but the *germen* is villous. *Desfont.*

9. S. *purgans*. Purging Broom. Willd. n. 8. Ait. n. 5. But not Linn. Syſt. Nat. ed. 12. v. 2. 474. (Geniſta purgans; Bulliard t. 115. G. ſive Spartium purgans; Bauh. Hiſt. v. 1. p. 2. 404.)—Branches round, furrowed. Leaves obovato-lanceolate; ſilky beneath. Flowers axillary, ſolitary; their ſtalks thrice the length of the calyx. Petals all ſmooth. Legume ſhaggy.—Native of the ſouth of France. We received it from the late Dr. Brouſſonet. The *ſtem* is woody, very much branched, and ſtrongly furrowed, not ſpinous. *Leaves* chiefly on the young branches, ſmall, ſtalked. *Flower-ſtalks* ſilky, as long as the leaves, or longer. *Calyx* partly ſilky. *Petals* yellow, ſhorter, and more rounded, than in *S. cinereum*, quite ſmooth, except the villous hairs, which knit thoſe of the keel together. *Legume* curved, denſely clothed with long ſhaggy hairs. Linnæus was really unacquainted with this ſpecies. His *Geniſta purgans*, Sp. Pl. 999, is a very ſpinous ſhrub, totally different from Bauhin's plant, and may be *S. ſcorpius*. His *S. purgans*, adopted from Gerard in the 12th edition of Syſt. Nat. is our *cinereum*, n. 6; yet we do not judge it right to interchange the ſynonyms, merely to countenance, ſtill leſs to conceal, a blunder of our great maſter, or of his learned correſpondent, Gerard. The two plants can never again be confounded.

10. S. *umbellatum*. Umbellate Broom. Desfont. Atlant. v. 2. 133. t. 180. Willd. n. 9. Ait. n. 6.—Branches round, ſtriated, leafy. Flowers capitate. Corolla ſilky, as well as the legume, and lanceolate leaves.—Native of the ſea-coaſt of Barbary. Sent to Kew by the late Dr. Brouſſonet. It is a greenhouſe ſhrub, flowering from April to June, very much branched, and readily known by its yellow, ſilky, capitate, rather than umbellate, *flowers*. *Legume* oblong, compreſſed, denſely villous, containing from three to five *ſeeds*. The *leaves* are often ternate, ſo that this ſpecies ought rather to ſtand in the next ſection, near *linifolium*.

11. S. *Scorpius*. Scorpion Broom. Linn. Sp. Pl. 995. Willd. n. 10. Ait. n. 7. Prodr. Fl. Græc. n. 1644. (Geniſta purgans; Linn. Sp. Pl. 999? G. ſpinoſa minor; Ger. Em. 1319. Aſpalathus alter tertius; Cluſ. Hiſt. v. 1. 106.)—Branches round, ſtriated, ſpreading, ſpinous. Flower-ſtalks axillary, aggregate. Leaves oblong, hairy, with a ſpinous point.—Native of Spain, the ſouth of France, Greece, and the Archipelago. Each of the *branches* ends in a ſharp thorn, and the young ones ſpread horizontally. The *leaves* are ſmall, oblong or obovate, looſely covered on both ſides with ſilky hairs. *Flowers* yellow, their ſtalks about as long as the leaves, and ſituated, like them, on the young branches only. We know nothing of the *legume*. Lamarck ſays it is ſmooth. The modern Greeks call this plant Αϛάνα.

12. S. *aſpalathoides*. Tubercular Thorny Broom. Deſfont. Atlant. v. 2. 136. Willd. n. 11. (Geniſta aſpalathoides; Lamarck Dict. v. 2. 620.)—Branches angular, tuberculated, ſpinous. Flower-ſtalks axillary, aggregate. Leaves linear-lanceolate, ſilky, unarmed.—Diſcovered by Poiret, on the coaſt of Barbary, near Tunis. The *ſtem* is much branched, two or three feet high; the *branches* beſet with ſcattered tubercles, and ending in ſharp thorns. *Leaves* in ſmall tufts upon the tubercles; alternate on the young ſhoots; ſmall, narrow, covered with ſhort, depreſſed, ſilky hairs. *Flowers* twice the ſize of the laſt, pale yellow, axillary, ſtalked, two or more together; their *ſtalks*, *calyx*, and *corolla* ſilky. *Germen* covered with white hairs.

Section 2. *Leaves moſtly ternate.*

13. S. *multiflorum*. Portugal White Broom. Ait. n. 8. Willd. n. 12. (S. album; Desfont. Atlant. v. 2. 132. S. diſpermum; Willd. in Rom. and Uſt. Mag. faſc. 11. 35. t. 2. Geniſta alba; Tabern. Kreuterb. 1509.)—Leaves ternate or ſimple, elliptic-lanceolate, ſilky. Branches ſtraight, ſtriated, covered with flowers. Legume ſilky, with two ſeeds.—Native of Portugal and Barbary. A hardy ſhrub in our gardens, flowering in May. The *ſtem* is from four to ſix feet high, with copious, erect, long, ſtraight, wand-like *branches*, covered from top to bottom with elegant, ſnow-white, ſtalked, axillary *flowers*. The *leaves* are but ſeldom ternate. The *legume* is ovate-oblong, compreſſed, dark brown, clothed with whitiſh hairs.

14. S. *angulatum*. Angular-branched Broom. Linn. Sp. Pl. 996. Willd. n. 13. Ait. n. 9. Sm. Fl. Græc. Sibth. t. 672, unpubliſhed. (S. parviflorum; Venten. Cels. t. 87.)—Leaves moſtly ternate, linear-oblong. Branches with ſix angles. Flowers terminal, racemoſe. Legume elliptical, acute at each end, with one or two ſeeds.—Native of the Levant. Hardy with us, flowering in May and June. Its aſpect is that of a Melilot, but the *ſtem* is ſhrubby, with numerous ſtraight upright *branches*, marked with three decurrent angles from the inſertion of each leaf. The *leaflets* are more or leſs obtuſe, nearly equal, ſlightly hoary, not an inch long. *Flowers* ſmall, yellow, numerous, compoſing long, ſolitary cluſters, at the end of each branch. *Legumes* pendulous, ſlightly hairy, compreſſed, thick-edged, three quarters of an inch long, having an annular appearance at each ſide from the projection of the uſually ſolitary *ſeed*.

15. S. *perſicum*. Perſian Broom. Willd. n. 14. (Cytiſus perſicus; Burm. Ind. 163. t. 51. f. 1.)—Leaves ternate, linear-lanceolate, ſtalked; the middle leaflet twice as large as the others. Branches divaricated, roundiſh. Flowers terminal, racemoſe.—Native of Perſia. A ſmall ſpecies, whoſe genus ſeems uncertain, and of which neither we nor Willdenow have ſeen any ſpecimen. There appears, however, ſome affinity between it and the laſt. The *flowers* evidently compoſe terminal cluſters. The *branches*, *ſtalks*, and *calyx* are downy.

16. S. *patens*. Woolly-podded Broom. Linn. Syſt. Veg. ed. 13. 535. Willd. n. 15. Ait. n. 10, excluding the ſynonym of Cavanilles. (Cytiſus patens; Linn. Syſt. Veg. ed. 13. 555. C. pendulinus; Linn. Suppl. 328. C. luſitanicus, medicæ folio, floribus in foliorum alis; Tourn.

Inſt. 648.)—Leaves ternate, ſtalked, obovate. Branches round, ſtriated. Flowers lateral, drooping. Calyx two-lipped, broad, ſilky. Germen very woolly.—Native of Portugal and Spain. Hardy in our gardens, flowering in June and July. The *branches* ſpread widely, and are clothed with numerous, ſtalked, ſilky *leaves*, uſually ſhorter than the large, tumid, pendulous, yellow *flowers*, which are moſtly ſolitary, ſometimes in pairs, by the ſide of each tuft of leaves, on ſimple ſilky ſtalks. The *calyx* is deeply divided, ſhallow, ſpreading widely, beſprinkled with ſilky hairs. *Petals* very large, ſmooth, rounded and obtuſe. *Germen* clothed with extremely long, woolly hairs, and ſheathed in the permanent *ſtamens*, but at length becoming an oblong, compreſſed, wavy, very hairy *legume*, containing ſeveral *ſeeds*. Whatever the plant of Cavanilles' Icones, t. 176, may be, its unequal *leaflets*, terminal corymboſe *infloreſcence*, long ſlender *calyx*, and ſmooth *germen*, are all ſo totally unlike the preſent ſpecies, that we wonder how even the moſt caſual peruſal of its name could cauſe it to be quoted by Willdenow for ſuch.

17. S. *nubigena*. Cluſter-flowered White Broom. Ait. ed. 1. v. 3. 13. ed. 2. n. 11. Willd. n. 16. (S. ſupranubium; Maſſon in Linn. Suppl. 319.)—Leaves ternate, ſtalked, lanceolate, hairy. Branches round, furrowed. Flowers lateral, aggregate. Upper lip of the calyx abrupt. Germen ſmooth.—Diſcovered by Mr. Maſſon, very high on the peak of Teneriffe, above the clouds, as he meant to expreſs in the ſpecific name. It is a greenhouſe plant at Kew, flowering moſt part of the ſummer. The buſhy *ſtem*, with its copious furrowed *branches*, much reſembles *S. junceum*, but the *leaves* are ternate, ſmall, and the *flowers* very much ſmaller than in that ſpecies, white and fragrant, ranged in lateral tufts along the branches, on ſilky ſtalks. The *calyx* is hairy or ſilky, cup-ſhaped; its lower lip elongated; upper ſhort and abrupt. *Legume* an inch and a half, or two inches long, curved, compreſſed, wavy, quite ſmooth.

18. S. *biflorum*. Two-flowered Terminal Broom. Desfont. Atlant. v. 2. 133. t. 179. Willd. n. 17.—Leaves ternate, linear-lanceolate, ſtalked, ſomewhat hairy. Flowers terminal, often in pairs. Calyx villous, its lips nearly equal. Legume ſmooth.—Native of mount Atlas, near Tlemſen. *Stem* buſhy, from one to two feet high, with ſlender, angular, leafy branches. *Leaves* ſmall, ſtalked, rather ſilky. *Flowers* yellow, erect, one, two, or three at the ſummit of each branch, rather ſmaller than thoſe of the common *S. ſcoparium*.

19. S. *linifolium*. Flax-leaved Broom. Desfont. Atlant. v. 2. 134. t. 181. Willd. n. 18. Ait. n. 12. (Geniſta linifolia; Linn. Sp. Pl. 997. Curt. Mag. t. 442. G. tinctoria hiſpanica; Cluſ. Hiſt. v. 1. 101. Geniſtella infectoria; Ger. Em. 1316.)—Leaves ſeſſile, ternate, linear-lanceolate, revolute; ſilky beneath. Cluſters terminal. Branches angular, furrowed.—Native of Barbary, Spain, and the ſouth of France. A hardy greenhouſe plant in England, flowering moſt plentifully in May and June. The *ſtem* is ſhrubby, much branched, and very leafy. *Leaves* about an inch long, rendered very beautiful by the ſilvery ſilkineſs of their under ſide, in which they agree with the *calyx* and young *branches*. *Flowers* of a beautiful golden yellow, in denſe tufted cluſters. *Legume* ſhort and broad, clothed with ſhaggy hairs. *S. umbellatum*, n. 10, having frequently many ternate *leaves*, and agreeing nearly with the preſent ſpecies in habit, *legume*, and *infloreſcence*, would perhaps have been better placed here.

26. S. *ſcoparium*. Common Broom. Linn. Sp. Pl. 996. Willd. n. 19. Fl. Brit. n. 1. Engl. Bot. t. 1339. Curt. Lond. faſc. 5. t. 52. Woodv. Med. Bot. t. 89. Fl. Dan. t. 313. Dreves Bilderb. t. 48. Ehrh. Arb. 56. (Geniſta; Ger. Em. 1311.)—Leaves chiefly ternate, ſtalked, obovate. Branches angular. Flowers lateral, ſolitary. Calyx two-lipped, broad, ſmooth. Legume fringed.—Common on ſandy or gravelly dry hills, principally in the north or middle of Europe. Abundant in Britain, flowering copiouſly in May and June, when it makes a highly ornamental appearance. The *ſtem* is very buſhy, from three to eight feet in height, with innumerable, aſcending, angular, ſmooth, evergreen twigs. *Leaves* deciduous, ſmooth or ſomewhat hairy; the upper ones generally ſimple. *Flowers* axillary, looſely pendulous, ſolitary, on long ſtalks, large, uſually of a golden yellow; ſometimes orange at the outſide; very rarely of a pale uniform lemon-colour: their *petals* ſpread widely in hot ſunny weather. *Calyx* bell-ſhaped, ſmooth, glaucous and purpliſh, with two widely-ſpreading lips, whoſe teeth are minute and downy. *Legume* compreſſed, two inches long, ſmooth, fringed at the margin with denſe deciduous hairs. *Seeds* numerous.

21. S. *arboreum*. Tree Broom. Desfont. Atlant. v. 2. 131. t. 177. Willd. n. 20. (Cytiſus foliis ſubrotundis glabris, floribus amplis glomeratis pendulis; Shaw Phyt. Afr. n. 191.)—Leaves ternate, ſtalked, obovate. Branches round, furrowed. Flowers lateral, aggregate, drooping. Calyx two-lipped, ſpreading. Legume ſilky, with cloſe-preſſed hairs.—Found by profeſſor Desfontaines on mount Atlas, and in vallies near Algiers. From eight to twelve feet high, with a *trunk* often as thick as the arm. It ſeems akin to the laſt, but more to *S. patens*, n. 16, of which Desfontaines ſuſpected it might be a variety. Their *foliage* indeed appears much the ſame, but the *flowers* of the preſent are more aggregate. The *legume* however ſeems to afford the moſt certain ſpecific difference, being twice as long as that of the *patens*, and covered with depreſſed ſilky hairs, not long and ſhaggy ones. Nothing is mentioned of the pubeſcence of the *calyx*, nor have we ſeen a ſpecimen: but its teeth are repreſented like thoſe of *patens*, much more conſpicuous than in *ſcoparium*.

22. S. *radiatum*. Starry Broom. Linn. Sp. Pl. 996. Willd. n. 21. Ait. n. 14. (S. ramis oppoſitis angulatis, foliis oppoſitis ſubulatis; Mill. Ic. v. 2. 173. t. 259. S. minimum montanum triphyllum; Column. Ecphr. 295. t. 294. f. 2. Geniſta radiata, ſive ſtellaris; Bauh. Hiſt. v. 1. p. 2. 399.)—Leaves ternate, oppoſite, linear; with ſhort, dilated, permanent footſtalks. Branches oppoſite or aggregate, angular. Cluſters capitate, terminal. Legume ovate, hairy.—Native of Italy and Carniola. Hardy with us, in mild winters at leaſt. Flowering in June and July. The great abundance of naked radiating *branches*, crowned with tufts of handſome yellow *flowers*, readily diſtinguiſh this ſpecies. The broad, ſhort, permanent, concave *footſtalks*, hardening into ſpinous-tipped ſcales, under the branches, are very remarkable. The linear ſilky *leaves*, being oppoſite and ternate, look as if whorled. The *calyx* is tubular, ſilky as well as the *keel*. *Legume* ſhort, broadly ovate, pointed, covered with long ſilky hairs, and containing ſeveral ſmall *ſeeds*.

23. S. *ferox*. Sharp-thorned Broom. Desfont. Atlant. v. 2. 136. t. 182. Willd. n. 22. Ait. n. 15. (Cytiſus foliis oblongis ſeſſilibus glabris, ſiliquis compreſſis incanis; Shaw Phyt. Afric. n. 194.)—Leaves partly ternate, elliptic-oblong, pointed. Branches ſtriated, with ſpinous points. Cluſters terminal. Legume linear, hoary.—Native of Barbary. The *ſtem* is three or four feet high, with numerous ſtraight leafy *branches*, which, after bearing each a terminal *ſpike*,

ſpike, or *cluſter*, of yellow *flowers*, become very ſharp thorns. The *leaves* are moſt of them ſimple, on ſhort ſtalks, nearly ſmooth; ſome of the lower ones ternate. *Corolla* ſmooth, oblong and ſlender, ſomewhat like *Geniſta tinctoria*. *Calyx* elongated. *Germen* ſilvery. *Legume* about an inch and a half long, linear, ſlightly curved, clothed with ſhort, cloſe-preſſed, hoary hairs. *Seeds* numerous.

24. S. *ſpinoſum*. Prickly Broom. Linn. Sp. Pl. 997. Willd. n. 23. Ait. n. 16. Desfont. Atlant. v. 2. 135. (Acacia altera Dioſcoridis; Lob. Ic. v. 2. 95. A. altera trifolia; Ger. Em. 1330. A. altera; Matth. Valgr. v. 1. 176.)—Leaves ternate, ſtalked, obovate. Flowers axillary. Calyx ſmooth. Branches ſtriated, with alternate, ſpreading, angular, furrowed thorns. Legume oblong, ſmooth.—Native of Italy, Spain, and Barbary. Gerarde appears to have cultivated it in 1596, and it is marked by Mr. Aiton, as a greenhouſe ſhrub, flowering in June and July; but we have ſeldom met with it in collections. The whole buſh is armed with very ſtrong, long and ſharp *thorns*, ſpreading in every direction. *Leaves* on long ſtalks, each of three equal, broadiſh-obovate, ſometimes emarginate, leaflets; rather hairy beneath. *Flowers* half the ſize of *S. ſcoparium*, ſolitary or aggregate, ſtalked. *Calyx* membranous, with obſolete teeth. *Legume* pendulous, compreſſed, thick-edged, ſlightly tumid, ſmooth, an inch and a half long, with from two to four *ſeeds*.

25. S. *villoſum*. Hairy-podded Thorny Broom. Vahl Symb. v. 2. 80. Willd. n. 24. Sm. Fl. Græc. Sibth. t. 673, unpubliſhed. (S. lanigerum; Desfont. Atlant. v. 2. 135. Cytiſus ſpinoſus creticus, ſiliquâ villis denſiſſimis longiſſimis et incanis obductâ; Tourn. Cor. 44.)—Leaves ternate, ſtalked, obovate. Flowers axillary. Calyx hairy. Branches furrowed, ſpinous, downy. Legume linear-oblong, very hairy.—Native of Gibraltar, Barbary, and Crete. Dr. Sibthorp found it every where in Greece and the iſles of the Archipelago, where it is known by the names of ασπᾶλαλος, or ασπάλαθεια, and he judged it to be the ασπαλαθος of Dioſcorides. This ſpecies flowers in its native country in April. We have never met with a garden ſpecimen. The habit of the whole plant is like the laſt, but the *ſpines* are all terminations of *branches*, which are finely downy, and neatly ſtriated. In the *flowers* we ſcarcely obſerve a difference, except the denſe hairineſs of the *calyx*; but the *germen* is exceſſively hairy, and the *legume* differs eſſentially in its narrower, more linear, form, and its denſe cloathing, of long ſhaggy hairs.

26. S. *horridum*. Many-thorned Broom. Vahl Symb. v. 1. 51. Willd. n. 25. Sm. Fl. Græc. Sibth. t. 674, unpubliſhed.—Leaves ternate, linear, folded, ſilky. Branches oppoſite, aggregate, furrowed, ſpinous. Flowers lateral. Legume ovate, hairy as well as the calyx.—Native of Spain, as well as of hills in Greece and the Archipelago. This is a very denſely branched *ſhrub*, like a furze buſh, beſet with innumerable, thorny, cluſtered, ſomewhat hairy, *branches*, bearing a very few and ſmall *leaves*. The *flowers* are yellow, but half the ſize of the laſt, placed two or three on each young branch, near its point. *Calyx* pale, two-lipped, hairy, as well as the *keel*, and little, tawny, ovate or rhomboid, pointed *legume*, which ſcarcely contains more than one ſeed.

The *S. complicatum*, Linn. Sp. Pl. 996, is now *Cytiſus divaricatus*, Willd. Sp. Pl. v. 3. 1119. Ait. Hort. Kew. v. 4. 319. Curt. Mag. t. 1387. Sm. Fl. Græc. Sibth. t. 704, unpubliſhed.—*Cytiſus* differs from *Spartium* in having the *filaments* ſeparated to the very bottom, into two diſtinct ſets, and the *germen* ſtalked. There is a general reſemblance in habit between ſome of the ſpecies to each other. More difficulty exiſts in diſtinguiſhing *Spartium* and *Geniſta*; the latter being characterized chiefly by the depreſſion of its organs of impregnation along with the *keel*, while the *ſtandard* is ſtrongly divaricated. The involute *ſtigma*, and the *ſtamens* not being attached to the *germen*, are leſs obvious diſtinctions. See Genista.

Three Linnæan ſpecies of *Spartium*, as we have already hinted, named *contaminatum*, *ſepiarium*, and *cytiſoides*, with one from the firſt edition of Aiton, *ſericeum*, all natives of the Cape of Good Hope, are removed by Thunberg from hence, and eſtabliſhed, with four other ſhrubs from the ſame country, as a diſtinct genus, named Lebeckia, in Thunberg's *Prodromus*, and in Willd. Sp. Pl. v. 3. 946. Ait. Hort. Kew. v. 4. 261. This ranges next after *Geniſta*, and is defined as follows.

Eſſ. Ch. Calyx in five deep acute ſegments, with rounded ſinuſes. Filaments monadelphous. Legume cylindrical, with many ſeeds.

Section 1. *Leaves ſimple.*

1. L. *contaminata*. Narrow-leaved Lebeckia. Willd. n. 1. Ait. n. 1. (Spartium contaminatum; Linn. Mant. 268.)—Leaves ſimple, linear-thread-ſhaped, ſmooth, ſtained at the baſe. Flowers racemoſe.—Native of ſandy ground at the Cape. *Stem* ſhrubby, branched, ſmooth and round. *Leaves* alternate, an inch and a half or two inches long, acute, glaucous; flattiſh above; purple at the baſe. *Flowers* in a long, ſimple, terminal *cluſter*, orange-coloured, with a yellow *keel*. The *ſtamens* are deſcribed as all equally combined. We know not by what accident Thunberg calls the *flowers* umbellate, which Willdenow copies, in direct contradiction to the Linnæan deſcription ſubjoined.

2. L. *ſepiaria*. Capillary Lebeckia. Willd. n. 2. (Spartium ſepiarium; Linn. Sp. Pl. 995. Lathyroides, vel lathyris congener, linariæ foliis, æthiopicum; Pluk. Mant. 114. Amalth. t. 424. f. 1. Yellow Cape Broom, with fennel leaves; Petiv. Gazoph. t. 83. f. 3.)—Leaves ſimple, capillary, ſmooth. Flowers racemoſe.—Native of the Cape, like all the reſt of the ſpecies. This has more copious, longer, and much ſlenderer *leaves* than the foregoing, with larger *flowers*, whoſe tenth *ſtamen* is ſeparated, in its upper part at leaſt, from the reſt.

3. L. *pungens*. Spinous Downy Lebeckia. Thunb. Prodr. 122. Willd. n. 3.—"Leaves ſimple, obovate. Branches downy, all becoming ſpinous at the end. Flowers ſolitary."

Section 2. *Leaves ternate.*

4. L. *armata*. Thorny Grey Lebeckia. Thunb. Prodr. 122. Willd. n. 4.—"Leaves ternate. Branches hoary, round, becoming thorny. Flowers racemoſe."

5. L. *denſa*. Denſe-leaved Lebeckia. Thunb. Prodr. 122. Willd. n. 5.—"Leaves ternate, villous; leaflets convolute, oblong. Flowers racemoſe, diſtant."

6. L. *humilis*. Dwarf Lebeckia. Thunb. Prodr. 122. Willd. n. 6.—"Leaves ternate, villous; leaflets linear-oblong. Flowers racemoſe, reflexed. Branches incurved."

7. L. *ſericea*. Silky Lebeckia. Thunb. Prodr. 122. Willd. n. 7. Ait. n. 2. (Spartium ſericeum; Ait. ed. 1. v. 3. 12.)—"Leaves ternate, ſilky; leaflets linear. Flowers racemoſe. Branches angular."—Sent by Mr. Maſſon to Kew, in 1774. It flowers in the greenhouſe, in April.

8. L. *cytiſoides*. Cytiſus-leaved Lebeckia. Willd. n. 8. Ait. n. 3. (Spartium cytiſoides; Linn. Suppl. 320. Ebenus capenſis; Linn. Mant. 264. Trifolium africanum fruticans, folio anguſtiore, flore rubicante; Commel. Hort. v. 2. 213. t. 107.)—Leaves ternate, ſilky; leaflets linear-lanceolate. Flowers racemoſe. Branches round.—Communicated by Thunberg to Linnæus. Maſſon ſent it from the Cape to

Kew garden in 1774, where it flowers in the greenhouſe, in April. We preſume this to be nearly akin to the laſt. The *leaves* in the original ſpecimen are ſilky, not villous; each *leaflet* above an inch long. *Flowers* large, in terminal ſolitary *cluſters*. *Calyx* bell-ſhaped, ſmooth, coloured. *Petals* reddiſh. *Legume* long, with the rudiments of many *ſeeds*, only one of which is ſaid to come to perfection.

Spartium, in *Gardening*, contains plants of the deciduous and evergreen kinds, among which the ſpecies cultivated are the common broom (S. ſcoparium); the Spaniſh broom (S. junceum); the ſtarry broom (S. radiatum); the white-flowered ſingle-ſeeded broom (S. monoſpermum); the yellow-flowered ſingle-ſeeded broom (S. ſphærocarpum); the ſcorpion broom (S. ſcorpius); the angular-branched broom (S. angulatum); and the prickly broom (S. ſpinoſum).

In the firſt ſpecies there are ſeveral varieties, ſome of which merit a place among flowering ſhrubs; as that with a purple calyx, and the flowers ſtrongly tinged with orange, as well as that which is very hoary.

The ſecond ſpecies has alſo a variety with double flowers.

Method of Culture.—The three firſt ſorts are hardy, but the others more tender, eſpecially in their young growth. And they are all capable of being raiſed from ſeeds, and the double-bloſſomed ſorts alſo by layers and cuttings. The ſeeds ſhould be ſown in the early ſpring, as about April; the hardy ſorts in beds of common earth, either in drills, or by bedding in to the depth of an inch: but in the tender ſorts, in pots or beds hooped over to protect them in froſty weather. In the following ſpring they ſhould be removed into nurſery-rows or larger pots, according to the kinds, ſhortening their tap-roots, and ſetting them out in rows two feet apart, at the diſtance of one in the rows, to remain two or three years, when they may be planted out in the ſhrubbery, or other places where they may be wanted: the tender ſorts in pots, being removed to the greenhouſe or garden for protection in winter, and managed as the hardy ſorts of plants of this kind.

But the layers ſhould be laid down in the autumn or ſpring, and the cuttings may be planted out in the ſpring or ſummer, ſome in the open ground, and others in pots plunged in the hot-bed, to promote their ſtriking root. They may be managed afterwards as the other ſorts. This is the only certain mode of preſerving the varieties.

All the hardy ſorts are very ornamental in the borders, clumps, and other parts, and the tender kinds in greenhouſe collections, and among other more hardy potted plants.

It is conſtantly proper, as a precautionary practice, to have ſome of the tender ſorts of theſe plants always in pots, under the greenhouſe management, with the view of more certainly preſerving them, in caſe thoſe which are planted out in the ſhrubberies or other parts of the open grounds ſhould ſuffer much or be wholly deſtroyed by the too great ſeverity of very ſevere winter ſeaſons. And as the long roots of the plants which are naked or but thinly ſet with fibres, are not unfrequently diſpoſed to run downwards with a long tap-root, they ſhould be planted out when young as much as poſſible where they are to remain and grow, as they do not ſucceed well, where they are tranſplanted or removed into a new ſituation when of a large or old growth.

Spartium *Scoparium*, *Common Broom*, in the *Materia Medica*. The tops and ſeeds are directed for uſe: the tops and leaves have a nauſeous bitter taſte, imparted by infuſion both to water and ſpirit. They are commended for their purgative and diuretic qualities, and have therefore been ſucceſsfully employed in hydropic caſes. Dr. Cullen ordered half an ounce of freſh broom-tops to be boiled in a pound of water till one half of this is conſumed, and gave of this decoction two table-ſpoonfuls every hour, till it operated by ſtool, or till the whole was taken. It ſeldom failed, he ſays, to operate both by ſtool and urine; and by repeating this exhibition every day, or every ſecond day, ſome dropſies have been cured. It is affirmed, that a patient, by taking half a pint of a decoction of green broom-tops, with a ſpoonful of whole muſtard-ſeed, every morning and evening, was cured, after being tapped three times, and trying the uſual remedies given in dropſies. The aſhes of broom have alſo been much uſed in dropſies, and principally on the authority of Sydenham, whoſe account of their good effects has been confirmed by the teſtimony of Dr. Monro, who gave a drachm divided into three doſes every day, and by other writers; the efficacy of this medicine depending entirely upon the alkaline ſalt, and not at all upon the vegetable from which it is obtained. The ſeeds and flowers of broom are ſaid to be emetic and cathartic; but the evidence upon which this aſſertion reſts is not wholly to be relied upon, as the former, when roaſted, have been uſed as a ſubſtitute for coffee, and the latter employed as a pickle. Ray informs us, from the MS. of Dr. Hulſe, that the flor. geniſt. given in the form of electuary, with honey of roſes, were found very efficacious in ſcrophulous affections. Woodv. Med. Bot.

SPARTOPOLIAS Lapis, in *Natural Hiſtory*, a name given by ſome authors to a whitiſh agate, variegated with long and ſlender ſtreaks of grey, diſpoſed in a variouſly undulated order, and reſembling grey hairs.

SPARUS, in *Ichthyology*, a genus of fiſhes of the order Thoracici, of which the generic character is; teeth generally ſtrong; the grinders ſomewhat obtuſe and crowded; the lips are doubled; gill-membrane five-rayed; the cover ſcaly; the body compreſſed; the lateral line curved on the hind part; the pectoral fins are rounded.

The name *ſparus* is of Greek origin, being derived from the verb σπαιρειν, *to palpitate* or *tremble*; and was given to this fiſh from its remarkable quality of trembling or palpitating all over the body, as ſoon as taken out of the water.

There are, according to Gmelin, about forty ſpecies, ſeparated into diviſions, and claſſed according to their colours; but Dr. Shaw has enumerated nearly four times that number. The greater number of ſpecies being exotic, little is known of their hiſtory; they are evidently allied to the Labri. See Labrus.

Species.

§ A. *Marked with a black Spot.*

*Auratus; or Lunated Gilt-head. The ſpecific character of this is, that between the eyes there is a ſemilunar ſpot. The general length of this fiſh is about fifteen inches; but occaſionally it is found of a far larger ſize: the body is broad and thin; the back riſing into a carina. Dr. Shaw gives the ſpecific character as ſilvery-blueiſh, with gold-coloured brows, and a purple ſpot beyond each ſide the head; but ſometimes, he ſays, with the addition of ſeveral browniſh longitudinal ſtripes. It is a native of the Mediterranean, Atlantic, and Indian ſeas, and held in conſiderable eſtimation as food. It was much admired by the ancient Greeks and Romans; by the former it was conſecrated to Venus. It feeds on ſhell-fiſh, which it grinds with its ſtrong teeth before it ſwallows. It is ſometimes found of the weight of eight or even ten pounds.

Annularis. Yellowiſh, with a black ocellate ſpot near the tail. This is found chiefly in the Adriatic. The colour of this ſpecies reſembles that of the common perch: at a certain diſtance from the baſe of the tail a round black ſpot is ſituated at the bottom of the laſt duſky bar of the body; the pectoral fins and tail are red, the reſt blackiſh. Native of the Mediterranean, and not at all in eſteem for the table.

Sargus. The body of this is marked with black bands, and a black ocellate ſpot near the tail. It inhabits the ſouthern coaſts of Europe. The body is oval, broad; the teeth are equal, obtuſe; and the tail forked. It is nearly of the ſize of the auratus, and the ſhape very like that, but deeper in proportion. It is much eſteemed as food.

Melanurus. Body with longitudinal lines and a black ocellate ſpot near the tail. This ſpecies is found in the ſouthern European ſeas. It is deſcribed by Shaw as ſilvery, with a blue back; the ſides have a ſtripe, ſpotted longitudinally with brown, and a black ſpot at the baſe of the tail.

Smaris. A black ocellate ſpot on each ſide; pectoral fins and tail red. It inhabits the Mediterranean.

Mœna. Body variegated; a blackiſh ſpot on each ſide. This is alſo found in the Mediterranean.

Saxatilis. Body whitiſh; a black ocellate ſpot at the baſe of the tail. This is found on the coaſts of Surinam. The ſnout is depreſſed; and the tail rounded.

Orphus. A black ocellate ſpot at the tail; the head is reddiſh; the tail is entire.

Punctata. Mouth cuſpidate; the tail entire; in colour it is partly black. It inhabits the ſhores of Sardinia. In ſize and colour it is nearly allied to the S. ſargus.

Argentatus. This has a black ſpot behind the gills. It is found on the coaſts of Japan; is ſix inches long; the body is covered with ſilvery ſcales; before the eyes are two noſtrils.

Notatus. Dorſal fin divided; the gill-covers and tail ſpotted with black. It is found at Japan. The head is coated with ſilvery ſcales, nearly as long as the fingers.

§ B. *Body moſtly red.*

Erythrinus. The tail of this fiſh is nearly entire; the body red. It inhabits the European, American, and Japan ſeas. It is often eaten, but is not held in any great eſtimation; and it has ſometimes proved poiſonous: the iris is ſilvery.

Insidiator. Body red, yellowiſh at the ſides; tail a little forked. It inhabits the Indian ocean; is about ten inches long; catches aquatic inſects, like the Chætodon roſtratus, with its ſnout, which it can lengthen out into a tube; the body is rather broad, fat, coated with large ſcales of a metallic-green colour at the edge; when dead it becomes brown; the fleſh is eatable. It is deſcribed as having a compreſſed head, and ſcaly; the eyes are lateral; jaws divided, each with two large ſtraight conic teeth in the middle; gill-covers very entire; firſt lateral line nearer the back, beginning at the end of the dorſal fin, the other ſtraight; the vent is nearly in the middle; the fins are yellowiſh; the dorſal and anal fins are marked with green bands; the laſt ray but one of the anal is very long.

* Formosus. Red; longitudinal marks on the body and tip of the tail blue. This fiſh is figured in Dr. Shaw's Naturaliſt's Miſcellany, and he ſuſpected that it was a Britiſh fiſh; hence it is marked with an aſteriſk. The fore-part of the dorſal, and edge of the anal fins, are blue.

* Pagrus; the Red Gilt-head. This is reddiſh; the ſkin, at the end of the dorſal and anal fins, gathered up, and hiding the laſt rays. It is found in the European ſeas. In ſhape, teeth, and ſize, it reſembles S. auratus. The iris is ſilvery; inſides of the gill-covers, mouth, and tongue, are of a fine red; at the baſe of the pectoral fins is a ferruginous ſpot; the ſcales are large; and the tail is forked.

Spinifer. Dorſal ſpines recumbent; the five middle ones filiform and longer. This inhabits the muddy deeps of the Red ſea; is about a ſpan and a half long. The body is ſilvery, but with a reddiſh hue; the back is marked with darker lines; the ſcales are broad, very entire, obſcurely ſtreaked, and the fleſh is reckoned excellent.

Palpebratus. This is of a cheſnut-red; the eyes are of a pale yellow, covered with a looſe yellowiſh membrane. This is found on the coaſts of Amboina. It reſembles a perch; but the head is more obtuſe.

§ C. *Body marked with Lines.*

Boops. Longitudinal lines duſky; the four lower ones are gold and ſilvery. It inhabits the ſea round Japan.

Cantharus. The tail is without ſpots; the body is marked with longitudinal lines. It inhabits the coaſt of Tuſcany. The iris is ſilvery.

Chromis. The tail is bifid; the ſecond ray of the ventral fin is ſetaceous. It inhabits ſouthern Europe.

Salpa. Tail bifid; the body is marked with eleven tawny longitudinal lines. It is found in the Mediterranean.

Sarba. This is of an oblong oval ſhape, ſilvery, with numerous obſolete ſtripes; the ventral fins are yellow, with a golden line on each ſide near them. It inhabits the Mediterranean, and along the coaſts of Arabia. The body is broad, and covered with broad entire ſcales; there are ſeventeen longitudinal browniſh ſtripes on each ſide; the fleſh is reckoned pleaſant.

Synagris. The tail is bifid, red; the body is purpliſh, with ſeven gold lines on each ſide. It inhabits South America.

Rhomboides. The tail is entire; the back is caniculate; the body with yellow lines. It inhabits America, and is there called the ſalt-water bream. The teeth are obtuſe; between the roots of the pectoral and dorſal fins a black ſpot; the ventral, anal, and caudal fins are tawny.

Latus. Yellowiſh; the head is ſilvery; the ſcales longitudinally imbricate. It inhabits about the coaſts of Japan; is three inches long, and one and a half broad.

Virgatus. The tail is forked; the body is depreſſed, oblong, ſtriped with ſcales. This is found on the coaſt of Japan.

Haffara. Silvery, with fourteen obſolete yellowiſh-brown lines on each ſide; the tail is bifid. It inhabits the muddy ſhores of Arabia; is about a ſpan long; and the fleſh is reckoned good.

Berda. Whitiſh-aſh; lateral ſcales with each a tranſverſe brown band in the middle; the dorſal ſpines are recumbent. It is found in the Red ſea. The body is oval; the back is gibbous, with obſolete bands; beneath it is white; the ſcales are broad, round, and entire.

Chilensis. The tail is bifid; the body is marked with tranſverſe brown lines on each ſide. It inhabits, as its ſpecific name denotes, Chili, in South America. It grows to full ſix feet long; in ſhape it is oval, depreſſed, coated with large rhomboidal margaritaceous ſcales, ſpotted with white; the fleſh is good.

§ D. *Various.*

Chrysops. The tail is ſemi-lunar; the back is grooved;

the iris is golden. It inhabits Carolina. The body is blueiſh.

ARGYROPS. Tail ſemi-lunar; the back is grooved; iris is ſilvery. It inhabits Jamaica and Carolina. It reſembles the laſt. The three firſt rays of the dorſal fin end in a long briſtle.

DENTEX. The tail is bifid; the body is variegated; four of the teeth are larger. It inhabits many parts of Europe, and the Cape of Good Hope.

SPINUS. Tail bifid; dorſal ſpine recumbent. It inhabits South America and India. The body is apparently painted with blue recurved blotches.

RADIATUS; Pudding-fiſh. The tail is entire; lateral line compoſed of linear ſcales, divided into three bifid branches. This is found on the coaſt of Carolina. Above it is a green purple at the ſides; beneath rufous; head varied with blue, yellow, and green ſtreaks.

VIRGINICUS. The tail is bifid; the body with two black tranſverſe bands, and numerous longitudinal lines. It inhabits North America.

MORMYRUS. The tail of this ſpecies is bifid; body with numerous ſilvery and black bands. It inhabits Tuſcany.

CAPISTRATUS. The tail of this is entire; the body is reticulate with white. It inhabits America. Body oblong; ſcales looſely imbricate, with a white band bent into a right angle before the edge.

GALILÆUS. The tail entire; body above is greeniſh, beneath white. It inhabits the lake Genezareth, in Galilee.

FUSCESCENS. Browniſh; ſcales golden; near the pectoral fins a black ſpot. It inhabits Japan, and is about four inches long.

* NIGER; Toothed Gilt-head. The back is black; the ſides brighter; belly ſilvery. This is found on the coaſts of Yorkſhire. It is deſcribed in Pennant's Britiſh Zoology. The body is twenty-ſix inches long, and ten broad; eyes large; teeth in the lower jaw ſlender, ſharp, and on each ſide a ſlender canine tooth, in the upper jaw a ſingle row; the firſt ſeven rays of the dorſal fin high, the reſt low; this fin and the anal covered with imbricate ſcales.

SPARUS, among the Romans, a kind of ruſtic weapon, bent backwards like the foot. It was likewiſe uſed for a ſmall dart, or miſſive weapon.

SPASA, in *Geography*, a town of Ruſſia, in the government of Archangel; 40 miles S.W. of Mezen.

SPASK, a town of Ruſſia, in the government of Kazan, on the Volga; 40 miles S. of Kazan. N. lat. 55°. E. long. 49° 14′.—Alſo, a town of Ruſſia, in the government of Tambov; 92 miles N.N.E. of Tambov. N. lat. 54° 2′. E. long. 42° 58′.—Alſo, a town of Ruſſia, in the government of Riazan, on the Oka; 32 miles E.S.E. of Riazan. N. lat. 54° 32′. E. long. 39° 50′.

SPASKAIA, a town of Ruſſia, in the country of the Coſſacks, on the Don; 52 miles S.S.W. of Arkadinſkaia. —Alſo, a town of Ruſſia, in the government of Upha; 8 miles S. of Verchouralſk.

SPASKOI, a town of Ruſſia, in the government of Kolivan. N. lat. 55° 38′. E. long. 86° 14′.—Alſo, a town of Ruſſia, in the government of Tobolſk; 36 miles N. of Tomſk.—Alſo, a town of Ruſſia, in the government of Tobolſk; 20 miles W. of Narim.—Alſo, a town of Ruſſia, in the government of Olonetz; 60 miles N.E. of Pudoga.

SPASM, in *Medicine*, σπασμος, from σπαω, *I draw*, or *contract*, a *cramp*, in its modern ſenſe, ſignifies a continued and painful contraction of a muſcle, or any portion of muſcular fibres; in which ſignification it ſtands in oppoſition to *convulſion*. This, however, appears to have been an arbitrary determination of its acceptation, which does not ſtrictly accord with the original uſe of the word. For Celſus has diſtinctly defined *ſpaſm*, as meaning convulſive motion, and applies the word *tetanus* to the rigid and fixed contraction, as we have ſtated in another place. "Modo nervorum diſtentionem, modo rigorem; illud σπασμὸς, hoc τετανος, Græcè nominatur." (De Medicinâ, lib. ii. cap. 1.) See CONVULSIONS. Some writers, however, have applied the term, ſpaſm, to both theſe forms of diſeaſe; uſing the epithet of *tonic* to ſignify the ſtate of rigid contraction, and *clonic* to denote the violent contractions and relaxations of convulſion. Others again have applied the word to every irregular action of the muſcular or moving fibres, in any part of the body. (See Cullen, Firſt Lines, par. 1251.) This latitude has led the celebrated author, juſt quoted, to bring together diſeaſes, which have very little reſemblance in the morbid actions which conſtitute them; as, for inſtance, hyſteria, diabetes, colic, and hydrophobia, which are claſſed together as *ſpaſmodic* affections of the natural functions, in his ſyſtem of noſology.

The various functions of the animal body are performed by certain contractions of the moving or muſcular fibres, in which alone that power is inherent. Theſe contractions are excited either by the will, in thoſe muſcles which obey the faculty of volition; or by certain ſtimuli or cauſes of irritation, appointed by nature for that purpoſe, in thoſe which are not under the influence of the will. The blood, for inſtance, excites the motions of the heart; the paſſing aliments produce the periſtaltic contractions of the bowels; and ſo forth. In a ſtate of health, the contractions are regulated in force and velocity by the will, or by theſe natural irritations; and whether produced by the one or the other, they are always ſoon ſucceeded by a ſtate of relaxation, and are not repeated, until the will or theſe natural excitements operate again. But in a morbid ſtate, the contractions of the moving fibres, ordinarily depending on the will, are excited without the concurrence of the will, or contrary to what it intends; and in the other functions, they are excited by the action of unuſual and unnatural cauſes, or, from too great mobility, are rouſed to more violent and continued contractions by the ordinary cauſes. When the contractions are more violent in degree than is uſual in health, and are neither ſucceeded by a ſpontaneous relaxation, nor even yield readily to an extenſion, either from the action of antagoniſt muſcles, or from other extending powers applied, this ſtate is called a *tonic ſpaſm*, or ſimply a *ſpaſm*. For an account of the ſucceſſive violent contractions and relaxations under this morbid excitement, ſee CONVULSIONS.

The preſence of ſpaſm, in any muſcular part, is indicated by intenſe *pain*, (and it muſt be obvious, from what has juſt been ſtated, that thoſe pathologiſts, who ſpeak of ſpaſmodic affections of nerves, membranes, and ſuch uncontractible parts, uſe an erroneous language;) a ſymptom, however, which occurs alſo in inflammation of the ſame parts: and as the remedies for inflammation are injurious in ſpaſm, and *vice verſâ*, it is always important to aſcertain the real origin of ſuch pain. The pain ariſing from ſpaſm commonly attacks very ſuddenly, or even inſtantaneouſly; it generally comes and goes, or is intenſe for a while, and then ſubſides at intervals, as the ſpaſm recurs and relaxes; it very often ſhifts its ſeat, as different portions of the muſcular fibres of any part are ſucceſſively contracted; and, above all, it is not attended with general fever, and the pulſe is neither accelerated, nor increaſed in hardneſs. The pain connected with inflammation of any organ is commonly more ſlow and gradual in its attack; it is accompanied or preceded by ſhivering; it is fixed both in reſpect to the intenſity and to the ſeat of it; and it is attended by ſymptoms of fever, heat of ſkin, a quick and hard pulſe, thirſt, &c. The *kind* of pain, too, is deſcribed as different: that of ſpaſm being accompanied by a ſenſe of conſtriction; while that of inflammation is combined with a ſenſe of ſtabbing or cutting, and often of throbbing, burning, &c.

Of theſe painful ſpaſmodic diſeaſes, the *tetanus* is the moſt formidable and fatal, in which all the voluntary muſcles are rigidly contracted, and the body and limbs ſtiffly extended; in ſhort, an univerſal cramp exiſts, and the pain of ſuch a condition may be conceived, if we conſider the ſuffering produced by a partial cramp. Sometimes the antagoniſt muſcles of the back are moſt affected, when the body is rigidly bent backwards, like a bow, and reſts upon the back of the head and the heels, when it is called *opiſthotonos;* and ſometimes the anterior muſcles are moſt contracted, and the bend is forwards, which is called *emproſthotonos*. (See Tetanus.) The jaw is firmly locked in this complaint; and when the ſpaſm is confined to that part, it is called Trismus, or locked-jaw; which ſee. Leſs formidable, though very painful, ſpaſms occur in the muſcular coat of the inteſtines, conſtituting *colic;* or in that of the ſtomach, which is uſually called *cramp in the ſtomach*. In hyſterical women, various cramps of theſe parts, and of the voluntary muſcles, are liable to occur. The fit of ſpaſmodic *aſthma* is principally produced by a ſpaſmodic contraction of the muſcular fibres about the larynx, and of the muſcles ſubſervient to reſpiration.

In the pathological doctrines of Dr. Cullen relative to the nature of fever, *ſpaſm* holds a diſtinguiſhed place, and is conſidered, indeed, as the eſſence of fever. This hypothetical ſpaſm was ſuppoſed by him to take place in the extremities of the arteries, and eſpecially of thoſe on the ſurface of the body, and to be demonſtrated by the paleneſs and ſhrinking of the external parts, and the ſuppreſſion of the excretions, conſtituting the cold fit; and the hot fit, which enſues, was believed to be an effort of the conſtitution, a reaction of the powers of life, and of the heart and arteries in particular, to overcome and to relax this ſpaſmodic conſtriction of the extreme veſſels; and this reaction, or fever, therefore, is ſeen to continue until the relaxation of the ſpaſm is effected. (See Firſt Lines of Pract. of Phyſic, par. 40. et ſeq.) We have confuted this hypotheſis at conſiderable length, in another place, (ſee Fever, *Dr. Cullen's Theory*,) and ſhall not dwell upon it here. It is altogether gratuitous, and unſupported by facts; but it has had conſiderable influence in modern practice.

The *cauſes of ſpaſm* may be reduced to two heads: *debility*, and its concomitant irritability, in the whole ſyſtem, or in particular organs, which are, therefore, excited to inordinate actions by the ordinary ſtimuli; and *irritation*, that is, the actual operation of unuſual and extraordinary ſtimuli. If theſe two cauſes are combined, it is obvious that any excitement, very little greater than ordinary, may produce violent ſpaſm, or very inordinate actions: whence it happens, that in conſtitutions of particular irritability, very ſlight irritations will occaſionally produce the moſt ſevere ſpaſmodic diſorders. Thus the moſt violent of all, the tetanus, is often occaſioned by a ſcratch or ſlight wound of the ſkin; and the locked-jaw of new-born infants appears to originate in the irritation of the meconium retained in the bowels. If the irritation of worms, and even morbid ſecretions, in the inteſtines are ſufficient, in children, to produce actual convulſions, it need not be matter of ſurpriſe that colic and cramp of the ſtomach ſhould be occaſioned, in irritable adults, by undigeſted food, and hot ſtimulating drinks. Very ſlight irritations, both external and internal, excite ſpaſms in ſuch habits; even the puncture of a needle (Mem. of the Med. Society of Lond. vol. ii.); and the preſſure of a tumour on a nerve, irritation from diſtended veſſels, or bony excreſcences in the cranium, have all given riſe to ſpaſm.

The *chief remedies* for ſpaſm are thoſe which leſſen irritability, or which excite increaſed power of action, or produce a ſudden and conſiderable commotion, and thoſe which remove the irritating cauſe. The firſt mentioned are uſually called *antiſpaſmodic* medicines. The moſt effectual of theſe are anodyne or narcotic ſubſtances, eſpecially opium, hyoſcyamus, and conium, which tend to leſſen the ſenſibility of the whole frame, and, therefore, to render it leſs liable to be acted upon by irritants. The term *antiſpaſmodic*, however, has been much applied to medicines of a ſtimulant quality, and eſpecially to ſome ſtrong-ſmelling ſubſtances, which alone are much leſs efficacious in relieving ſpaſm than the narcotics. Of the latter claſs are muſk, caſtor, camphor, and aſſafœtida; and of the more ſtimulant claſs are alcohol, æther, ammonia, the eſſential oils, &c. Perhaps the moſt efficacious remedy is compoſed by uniting the latter with the anodynes; for we know of no relief to violent ſpaſmodic pain more effectual than that produced by a combination of laudanum with æther. Among the ſtimulants that are often remedial in caſes of ſpaſm, *heat* is not the leaſt important. Fomentations, hot water, a hot brick, a bag of heated bran, &c. applied externally near the ſeat of ſpaſm, will often afford ſpeedy relief; and a large draught of hot water, taken as warm as the ſtomach will bear it, has produced a ſimilar good effect.

It is probably chiefly from the ſtimulant effect of violent emotions that relief is obtained from them in ſpaſmodic pain; but ſudden terror, or ſurpriſe, or apprehenſion, have ſucceeded in removing it. The influence of mental emotions, indeed, both in producing and curing ſpaſm, and even convulſions of the moſt violent nature, is equally curious and inexplicable. See Imitation and Convulsions.

Where ſpaſm depends upon irritation, the cauſe muſt be inveſtigated, and, if poſſible, removed by appropriate remedies, if within their reach. Thus clearing the bowels, where there is an obvious irritation from worms, undigeſted aliment, morbid bile, &c. will ſometimes entirely remove the ſpaſms. In order to prevent a recurrence, by invigorating the ſyſtem, and thus leſſening its irritability, after the ſpaſms have been ſubdued, it is often neceſſary to reſort to the uſe of tonic remedies. Of theſe a great variety has been employed, at different periods, with various reputation. Cold bathing, the uſe of the ſhower-bath, or tepid bathing, as at Buxton, may be conſidered as one of the moſt effectual tonics; after which may be mentioned ſome of the metallic tonics, ſuch as the various preparations of iron, copper, zinc, and ſilver, all of which are often efficient remedies. The cinchona, columba, caſcarilla, gentian, and other vegetable aromatic bitters, with or without an addition of the mineral acids, have alſo their value as tonics, and contribute to reſtore vigour and leſſen irritability in debilitated habits.

SPASMODIC, ſomething belonging to a ſpaſm, or convulſion; as ſpaſmodic medicine, ſpaſmodic diſeaſe, &c.

Hunger, according to M. Hecquet, is a ſpaſmodic affection of the fibres of the ſtomach; unleſs it ariſe from the fibres being too much moiſtened by the liquors thereof, ſo as to incapacitate them for their office. See Hunger.

SPAT, a term uſed by the fiſhermen for the ſpawn of oyſters, which is caſt in the month of May.

SPATAGOIDES, in *Natural Hiſtory*, the name of a genus of the echini marini, the characters of which are, that it has the aperture for the anus on one ſide of the upper ſurface, and has a large furrow on the back, which makes it of a cordated form; but has no furrows on the vertex, but only four or five ſmooth rays, made of a number of ſlight tranſverſe ſtriæ.

SPATALLA, in *Botany*, a name of Mr. Saliſbury's.—Brown Tr. of Linn. Soc. v. 10. 143. Ait. Hort. Kew. v. 1. 203.—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*, Juſſ. Brown.

Eſſ. Ch. Corolla four-cleft. Stamens in the concave tips of the ſegments. Nectary four ſcales beneath the germen. Stigma oblique, dilated. Nut ſuperior. Involucrum of from two to four leaves, containing one, or a very few, flowers. Common receptacle naked.

An occaſional irregularity in the *corolla*, and the oblique *ſtigma*, are the only characters which diſtinguiſh this genus from *Sorocephalus;* for in habit they ſtrictly accord. We cannot but, therefore, adviſe their union, under the latter name, whoſe derivation is the beſt.

The ſpecies of *Spatalla*, defined by Mr. Brown, are 15, one of which only finds a place in Mr. Aiton's work. They are diſpoſed in two ſections, of each of which we ſhall give an example or two.

Section 1. *Involucrums ſingle-flowered. Stigma concave, ſpoon-ſhaped. Corolla unequal.* Ten ſpecies.

S. *mollis*. Soft Spatalla. Br. n. 1.—"Involucrum of two entire leaves. Leaves ſtraight, villous, as well as the young branches."—Native of hills at the Cape of Good Hope. Communicated by Mr. John Roxburgh, to Mr. Lambert. An upright *ſhrub*, with copious reddiſh *branches;* the young ones ſlender, erect. *Leaves* ſlightly ſpreading, ſeven or eight lines long, ſilky with moderately ſpreading hairs, and tipped with a very ſharp callous point. *Spike* ſeſſile, erect, ſolitary, denſe, racemoſe, of an oblong cylindrical ſhape, hardly an inch in length. *Bracteas* leafy, twice as long as the partial flower-ſtalks. *Involucral leaves* ovate, villous, the outer one broadeſt. *Corolla* denſely bearded, purpliſh; the marginal hairs of its larger ſegment inflexed. *Scales* under the germen linear permanent.

S. *prolifera*. Proliferous Spatalla. Br. n. 8. (Protea prolifera; Thunb. Diſſ. n. 27. t. 4. Linn. Suppl. 118. Willd. Sp. Pl. v. 1. 518.)—Involucrum of four leaves, withered at the points. Spike in a conical head. Flowers nearly ſeſſile. Stem proliferous.—Native of hills at the Cape of Good Hope. An upright *ſhrub*, from a foot and a half to two feet high, much branched in a proliferous and umbellate manner; the young branches ſomewhat ſilky. *Leaves* cloſely imbricated, hardly three-quarters of an inch long, awl-ſhaped; ſilky on the younger branches. *Spikes* ſeſſile, ſolitary, terminal, but ſurmounted by ſubſequent branches from their baſe. *Corolla* very denſely ſilky; its outer ſegment twice as large as the others. *Stigma* flattiſh, with a central tubercle.

Section 2. *Involucrums with three or four flowers. Stigma rather convex. Corolla almoſt equal.* Five ſpecies.

S. *incurva*. Incurved-leaved Spatalla. Br. n. 11. Ait. n. 1. (Protea incurva; Thunb. Diſſ. n. 22. t. 3. Willd. Sp. Pl. v. 1. 516.)—Spikes racemoſe, ſomewhat ſtalked. Involucrum downy, longer than the bracteas, with about four flowers. Leaves incurved. Corolla unequal.—Native of moiſt, ſandy, rather ſhady ſituations at the Cape of Good Hope. Mr. Maſſon ſent it, in 1789, to Kew, where it flowers in May and June. The *leaves* are numerous, ſlender, above an inch long, ſpreading, aſcending at the points. *Spikes* generally aggregate, oblong, lax. *Bracteas* nearly the length of the partial ſtalks. Mr. Brown notices a variety, or perhaps diſtinct ſpecies, whoſe *leaves* are ſhorter and more crowded, *ſpikes* ſolitary, and *bracteas* longer than the partial ſtalks. *S. incurva* bears a cloſe reſemblance to ſome ſpecies of CONOSPERMUM. See that article.

The deſcriptions of the genera of SOROCEPHALUS (ſee that article), and *Spatalla*, ſuggeſt to us a doubt whether the ſpecies of theſe genera may not, in ſome inſtances at leaſt, differ ſexually only from each other. Not having ſeen many of them, we cannot examine critically into each ſpecies, but, in a general view, the male organs ſeem moſt perfect in *Sorocephalus*, the female in *Spatalla*. The regularity or irregularity of the *corolla* does not ſeem, in this caſe, to conſtitute a ſufficient generic difference.

SPATANGI, in *Natural Hiſtory*, the name of a genus of the echini marini, including all thoſe which are marked in the ſhape of a heart, and have the aperture for the anus in one of the ſides of the upper ſuperficies. Theſe have all a remarkable furrow on the back; their baſe is nearly flat, and they have ſeveral furrows on the vertex. By theſe characters they are diſtinguiſhed from the briſſi, with which they have in common the marks of two lips to their mouth, and want the teeth which the other kinds have.

SPATAREI, in *Geography*, a town of the iſland of Samos; 5 miles S.S.W. of Cora.

SPATARO, GIOVANNI, of Bologna, in *Biography*, the diſciple of Ramis, a Spaniard, the firſt modern who ſuſtained the neceſſity of a temperament; which gave birth to a controverſy among muſicians in Italy, that continued with great warmth during many years, and which has been revived in France during the latter end of the laſt century, with due polemic heat, by the writings of the abbé Rouſſier. (See PYTHAGORAS.) Spataro publiſhed a work in defence of his maſter's opinion, in which he treated the venerable Franchinus, and even Guido himſelf, with great obloquy, for not having diſcovered the neceſſity of a temperament. See RAMIS.

SPATHA, is a word uſed by different authors in various ſenſes: ſome expreſs by it a rib; others the inſtrument called by ſurgeons a ſpatula, and is uſed for ſpreading ointments and plaſters; and Celſus calls a ſort of inciſion-knife by this name. It is alſo uſed for the external covering of the fruit of the palm-tree, and by others for a ſword. This laſt is indeed its proper ſignification, and all the others are only metaphorical applications of it to different things, which bear ſome reſemblance to a ſword.

SPATHA, in *Botany* and *Vegetable Phyſiology*, a Sheath, is a ſort of CALYX, according to Linnæus, (ſee that article,) more or leſs remote from the flower, of which, therefore, it does not, like the *perianthium*, properly make a part. If of one valve only, it burſts longitudinally, as in the Narciſſus and Snow-drop; but it often conſiſts of many membranous valves, leaves, or ſcales, as in *Sowerbæa, Pancratium*, &c. The natural order of *Palmæ* exhibits various kinds of *Spathæ*, in great perfection, each encloſing a branched many-flowered SPADIX. (See that article.) Perhaps, nevertheleſs, this organ might more correctly be eſteemed of the nature of a *Bractea*, or floral leaf, not conſtituting, in any caſe, a part of the fructification, nor affording any ſhare of the generic characters. We cannot but confeſs, that the more cloſely the definitions of genera are reſtricted to the real organs of the flower and fruit, without recurring to the infloreſcence, or any of its accompaniments, the more correct and philoſophical the ſcience of Botany has always appeared in our eyes. Linnæus, led by Artedi, ſwerves ſhivering; it is fixed both in reſpect to the intenſity and to the ſeat of it; and it is attended by ſymptoms of fever, heat of ſkin, a quick and hard pulſe, thirſt, &c. The *kind* of pain, too, is deſcribed as different: that of ſpaſm being accompanied by a ſenſe of conſtriction; while that of inflammation is combined with a ſenſe of ſtabbing or cutting, and often of throbbing, burning, &c.

Of theſe painful ſpaſmodic diſeaſes, the *tetanus* is the moſt formidable and fatal, in which all the voluntary muſcles are rigidly contracted, and the body and limbs ſtiffly extended; in ſhort, an univerſal cramp exiſts, and the pain of ſuch a condition may be conceived, if we conſider the ſuffering produced by a partial cramp. Sometimes the antagoniſt muſcles of the back are moſt affected, when the body is rigidly bent backwards, like a bow, and reſts upon the back of the head and the heels, when it is called *opiſthotonos;* and ſometimes the anterior muſcles are moſt contracted, and the bend is forwards, which is called *emproſthotonos.* (See TETANUS.) The jaw is firmly locked in this complaint; and when the ſpaſm is confined to that part, it is called TRISMUS, or locked-jaw; which ſee. Leſs formidable, though very painful, ſpaſms occur in the muſcular coat of the inteſtines, conſtituting *colic;* or in that of the ſtomach, which is uſually called *cramp in the ſtomach.* In hyſterical women, various cramps of theſe parts, and of the voluntary muſcles, are liable to occur. The fit of ſpaſmodic *aſthma* is principally produced by a ſpaſmodic contraction of the muſcular fibres about the larynx, and of the muſcles ſubſervient to reſpiration.

In the pathological doctrines of Dr. Cullen relative to the nature of fever, *ſpaſm* holds a diſtinguiſhed place, and is conſidered, indeed, as the eſſence of fever. This hypothetical ſpaſm was ſuppoſed by him to take place in the extremities of the arteries, and eſpecially of thoſe on the ſurface of the body, and to be demonſtrated by the paleneſs and ſhrinking of the external parts, and the ſuppreſſion of the excretions, conſtituting the cold fit; and the hot fit, which enſues, was believed to be an effort of the conſtitution, a reaction of the powers of life, and of the heart and arteries in particular, to overcome and to relax this ſpaſmodic conſtriction of the extreme veſſels; and this reaction, or fever, therefore, is ſeen to continue until the relaxation of the ſpaſm is effected. (See Firſt Lines of Pract. of Phyſic, par. 40. et ſeq.) We have confuted this hypotheſis at conſiderable length, in another place, (ſee FEVER, *Dr. Cullen's Theory*,) and ſhall not dwell upon it here. It is altogether gratuitous, and unſupported by facts; but it has had conſiderable influence in modern practice.

The *cauſes of ſpaſm* may be reduced to two heads: *debility*, and its concomitant irritability, in the whole ſyſtem, or in particular organs, which are, therefore, excited to inordinate actions by the ordinary ſtimuli; and *irritation*, that is, the actual operation of unuſual and extraordinary ſtimuli. If theſe two cauſes are combined, it is obvious that any excitement, very little greater than ordinary, may produce violent ſpaſm, or very inordinate actions: whence it happens, that in conſtitutions of particular irritability, very ſlight irritations will occaſionally produce the moſt ſevere ſpaſmodic diſorders. Thus the moſt violent of all, the tetanus, is often occaſioned by a ſcratch or ſlight wound of the ſkin; and the locked-jaw of new-born infants appears to originate in the irritation of the meconium retained in the bowels. If the irritation of worms, and even morbid ſecretions, in the inteſtines are ſufficient, in children, to produce actual convulſions, it need not be matter of ſurpriſe that colic and cramp of the ſtomach ſhould be occaſioned, in irritable adults, by undigeſted food, and hot ſtimulating drinks. Very ſlight irritations, both external and internal, excite ſpaſms in ſuch habits; even the puncture of a needle (Mem. of the Med. Society of Lond. vol. ii.); and the preſſure of a tumour on a nerve, irritation from diſtended veſſels, or bony excreſcences in the cranium, have all given riſe to ſpaſm.

The *chief remedies* for ſpaſm are thoſe which leſſen irritability, or which excite increaſed power of action, or produce a ſudden and conſiderable commotion, and thoſe which remove the irritating cauſe. The firſt mentioned are uſually called *antiſpaſmodic* medicines. The moſt effectual of theſe are anodyne or narcotic ſubſtances, eſpecially opium, hyoſcyamus, and conium, which tend to leſſen the ſenſibility of the whole frame, and, therefore, to render it leſs liable to be acted upon by irritants. The term *antiſpaſmodic*, however, has been much applied to medicines of a ſtimulant quality, and eſpecially to ſome ſtrong-ſmelling ſubſtances, which alone are much leſs efficacious in relieving ſpaſm than the narcotics. Of the latter claſs are muſk, caſtor, camphor, and aſſafœtida; and of the more ſtimulant claſs are alcohol, æther, ammonia, the eſſential oils, &c. Perhaps the moſt efficacious remedy is compoſed by uniting the latter with the anodynes; for we know of no relief to violent ſpaſmodic pain more effectual than that produced by a combination of laudanum with æther. Among the ſtimulants that are often remedial in caſes of ſpaſm, *heat* is not the leaſt important. Spataro publiſhed a work in defence of his maſter's opinion, in which he treated the venerable Franchinus, and even Guido himſelf, with great obloquy, for not having diſcovered the neceſſity of a temperament. See RAMIS.

SPATHA, is a word uſed by different authors in various ſenſes: ſome expreſs by it a rib; others the inſtrument called by ſurgeons a ſpatula, and is uſed for ſpreading ointments and plaſters; and Celſus calls a ſort of inciſion-knife by this name. It is alſo uſed for the external covering of the fruit of the palm-tree, and by others for a ſword. This laſt is indeed its proper ſignification, and all the others are only metaphorical applications of it to different things, which bear ſome reſemblance to a ſword.

SPATHA, in *Botany* and *Vegetable Phyſiology*, a Sheath, is a ſort of CALYX, according to Linnæus, (ſee that article,) more or leſs remote from the flower, of which, therefore, it does not, like the *perianthium*, properly make a part. If of one valve only, it burſts longitudinally, as in the Narciſſus and Snow-drop; but it often conſiſts of many membranous valves, leaves, or ſcales, as in *Sowerbæa*, *Pancratium*, &c. The natural order of *Palmæ* exhibits various kinds of *Spathæ*, in great perfection, each encloſing a branched many-flowered SPADIX. (See that article.) Perhaps, nevertheleſs, this organ might more correctly be eſteemed of the nature of a *Bractea*, or floral leaf, not conſtituting, in any caſe, a part of the fructification, nor affording any ſhare of the generic characters. We cannot but confeſs, that the more cloſely the definitions of genera are reſtricted to the real organs of the flower and fruit, without recurring to the infloreſcence, or any of its accompaniments, the more correct and philoſophical the ſcience of Botany has always appeared in our eyes. Linnæus, led by Artedi, ſwerves from this correctneſs in the *Umbelliferæ;* and for want of ſufficient information reſpecting the flowers and fruit of all the *Palmæ*, he was obliged to advert to other parts, to found any thing like plauſible genera. Such aberrations from his own laws ſhould rather be reformed, by thoſe who have the means, than ſerve as examples for laxity of principle in other inſtances. The greateſt artiſts ever require the feweſt tools, and moſt ſimple materials; and the human intellect never makes ſuch attainments as when neceſſarily put to its utmoſt exertions. Natural hiſtory, when ſtudied with all the accuracy and intenſity of which it is capable, becomes as inſtructive and philoſophical a ſchool for the mind as any ſcience whatever; nor does any one require more deep judgment, as well as preciſe obſervation.

SPATHALIUM, among the Romans, an ornament which the women wore about their hands, not unlike the coral ones of the moderns.

SPATHELIA, in *Botany*, altered from Dr. Patrick Browne's name for the ſame plant, *Spathe*, and alluding to the ſimple undivided ſtem, crowned with a tuft of luxuriant leaves, like the Palm tribe; *σπαθη* being a palm-tree, or palm-branch.—Linn. Gen. 148. Schreb. 198. Willd. Sp. Pl. v. 1. 1496. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 171. Juſſ. 371. Lamarck Illuſtr. t. 209. Gærtn. t. 58. (Spathe; Browne Jam. 187.)—Claſs and order, *Pentandria Trigynia*. Nat. Ord. *Terebintaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five oblong, coloured leaves. *Cor.* Petals five, oblong, equal. *Stam.* Filaments five, awl-ſhaped, aſcending, furniſhed with a tooth at the baſe; anthers ovate. *Piſt.* Germen ovate, ſhorter than the ſtamens; ſtyles three, very ſhort; ſtigmas three, roundiſh. *Peric.* Capſule oblong, triangular, with three wings, of three cells, not burſting; each cell furniſhed with a lateral channel, full of reſin. *Seeds* ſolitary, oblong, priſmatic, or nearly cylindrical, tapering at each end.

Eſſ. Ch. Calyx of five leaves. Petals five. Capſule with three winged angles, and three cells. Seeds ſolitary.

Obſ. Gærtner remarks, that the capſule is ſometimes compreſſed, with two oppoſite wings only, and two cells; but this ſeems to ariſe merely from a failure of impregnation of one of the ſtigmas.

1. S. *ſimplex.* Sumach-leaved Spathelia. Linn. Sp. Pl. 386. Willd. n. 1. Ait. n. 1. (Aceri aut paliuro affinis arbor, caudice non ramoſo, foliis ſorbi ſylveſtris, floribus pentapetalis racemoſis ſpecioſis purpureis, fructu ſicco tribus membranulis extantibus alato; Sloane Jam. v. 2. 28. t. 171.)—Plentiful by the ſides of rivers, among the rocky hills of Jamaica, according to Sloane and Browne. The latter erroneouſly calls it the Maiden-plum tree. This very handſome plant is ſaid to have been introduced into the ſtoves of England, in 1778, by Dr. William Wright. The *root* is of a ſpreading nature, not ſtriking deep. *Stem* quite ſimple and erect, an inch thick, naked, round, riſing like a palm-tree, Sloane ſays, to the height of 40 feet, and crowned at the ſummit with a large tuft of pinnate, crenate, ſpreading *leaves*, ſurmounted, in the flowering ſeaſon, with a vaſt compound *panicle*, many feet in height, of handſome purple *flowers*. The *capſules* are about an inch long.

SPATHESTER, the name of a chirurgical inſtrument uſed to draw the prepuce over the glans.

SPATHINUS, in *Natural Hiſtory*, a name given by the Greeks to the ſtag or deer, when in its ſecond year.

In the firſt, it was called *nebrus;* in the third year, *dicrotus;* and after this *ceraſtes*, as long as it lived.

SPATHIUM, in *Botany*, ſo denominated by Loureiro, from *σπαθιὸν*, *a little ſheath*, alluding to the form of its calyx.—Loureir. Cochinch. 217.—Claſs and order, *Hexandria Trigynia*. Nat. Ord. *Inundatæ*, Linn. *Naïades*, Juſſ.

Gen. Ch. *Cal.* Sheath ſtalked, of one leaf, roundiſh, ſpreading, ſingle-flowered. *Cor.* none. *Stam.* Filaments ſix, ſhort, inſerted into the receptacle; anthers roundiſh, of two cells. *Piſt.* Germen (ſuperior) roundiſh, with four horns; ſtyle none; ſtigmas four, oblong, reflexed. *Peric.* Berries four, ovate, pointed, ſingle-ſeeded. *Seeds* roundiſh.

Eſſ. Ch. Sheath roundiſh, ſtalked, ſingle-flowered. Corolla none. Berries four, with ſingle ſeeds.

1. S. *chinenſe.* *Thong pin ngau* of the Chineſe.—Native of marſhy places, near Canton in China. The *ſtem* is erect, three feet high, herbaceous, with ſpreading, flaccid, furrowed *branches*. *Leaves* heart-ſhaped, lanceolate, five-ribbed, ſmooth, ſcattered, with claſping *footſtalks*. *Spikes* linear, nearly terminal. Such is the deſcription of Loureiro, who conceives the above plant to be ſomewhat akin to the Linnæan *Aponogeton*, and alſo to *Potamogeton*. We have no acquaintance with it.

SPATHODEA, a genus founded by Paliſot de Beauvois, in his *Flore d'Oware & de Benin*, on ſome of the Linnæan *Bignoniæ*, and named from the ſheath-like form of their calyx. It is adopted by Mr. Brown, in his Prodr. Nov. Holl. v. 1. 471, under the following character.

Calyx ſheath-like, cloven down one ſide, either toothed or entire at the end. Corolla ſomewhat funnel-ſhaped, with a five-lobed, rather unequal, limb. Stamens two long and two ſhort, with a fifth abortive filament. Capſule pod-like, falcate, imperfectly four-celled. *Partition* tranſverſe, corky.

The genus is ſhrubby or arboreous; with oppoſite, rarely alternate, pinnate *leaves*, ſometimes ſimple. *Flowers* moſtly panicled.

Bignonia ſpathacea, ſee Bignonia, n. 18, is an example of *Spathodea*, as is alſo *S. heterophylla*, and perhaps *alternifolia*, of Brown.

SPATHOMELE, a word uſed by ſome to expreſs the ſpatula, uſed by the apothecaries and ſurgeons in mixing and ſpreading ointments and plaſters.

SPATHOSE, in *Mineralogy*, having a cryſtalline ſtructure.

SPATHULARIA, in *Botany*, from the ſpatulate ſhape of its head, a genus of *Fungi*, conſiſting of only one ſpecies.—Perſoon Syn. Fung. 610.—Claſs and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*. Sect. *Gymnocarpi*, *helvelloidei*.

Eſſ. Ch. Club-ſhaped. *Head* compreſſed, membranous, decurrent at each ſide.

1. S. *flavida.* Yellow Spathularia. Perſ. Diſp. Meth. 36. Comment. 34—36. (Clavaria Spathula; Dickſ. Crypt. faſc. 1. 21. Fl. Dan. t. 658. C. ſpatulata glabra; Schmid. Ic. t. 50. Elvela ſecunda; Schæff. Fung. t. 149. Helvella ſpatulata; Sowerb. Fung. t. 35.)—Found in fir woods, in autumn. Mr. Crowe firſt diſcovered it at Coſſey, near Norwich, where, in the plantations of ſir George Jerningham, it is very abundant, growing erect, in tufts. The *ſtalk* is about a finger's length, half an inch in diameter, hollow, rather uneven, whitiſh. *Head* vertical, obtuſe, hollow, ſomewhat obovate, or inverſely heart-ſhaped, pale buff, or yellowiſh, diſcharging innumerable minute *ſeeds*, in the form of ſmoke, from marginal pores. See Clavaria, n. 17.

SPATIUM, Lat., ſpace, is applied to the void between the lines of the ſtaff, upon which muſic is written. Spaces at firſt were not uſed, but there was a line for every ſound (ſee Notation); but when the lines were reduced to four, as in the canto fermo of the Romiſh ritual, and afterwards increaſed to five, as in the preſent ſecular muſic, the ſpaces came into uſe; and the loweſt was called the firſt, and ſo on to the fourth, fifth, and ſixth, which unites the baſe with the treble. See Riga, Lines, and Staff.

SPATLING-Poppy, a name given to the common field-lychnis, a ſpecies of cucubalus, from the white froth found on it in the ſpring. See Froth-*Spit*.

SPATOLA, in *Geography*, a town of Naples, in Calabria Ultra; 14 miles S. of Squillace.

SPATTERDASHES, a kind of covering for the legs, made of leather, &c. Thoſe of ſoldiers are made of coarſe linen, waxed over and buttoned tight.

SPATTS, a ſmall ſort of ſpatterdaſhes, reaching only a little above the ankle.

SPATULA, or Spathula, formed from *ſpatha*, of the Greek, σπαθιον, which ſignifies the ſame; an inſtrument uſed by ſurgeons and apothecaries; made flat at one end, and round at the other; ſerving to ſpread their plaſters and unguents.

The ſurgeons have little ſteel ſpatulas. And the apothecaries have alſo large ones of wood, to ſtir their drugs in diluting, tempering, or boiling them.

The ſpatula is uſed by ſurgeons to depreſs the tongue, in order to examine the ſtate of the tonſils, uvula, and fauces, when they are affected with any diſorders. It is alſo uſed to ſuſpend the tongue, when the frænum is to be divided; for which purpoſe it has a fiſſure at its extremity, and ſhould rather be made of ſilver than of any other metal. Theſe ſpatulæ are made of different ſhapes.

SPAVIN, formed from the French *eſparvin*, which ſignifies the ſame; a diſeaſe in a horſe: being a ſwelling or ſtiffneſs, uſually in the ham, which cauſes him to halt.

There are two kinds of ſpavins, *viz.* the *ox*, which is a callous tumour, at the bottom of the ham, on the inſide, hard as a bone, and very painful. While it is yet young, ſome horſes only halt with it at the firſt coming out of the ſtable. The *dry* ſpavin is more eaſily perceived, by the horſe's raiſing one of his hind-legs, with a twitch, higher than the other: but ſometimes it is found in both legs.

This kind, which ſome alſo call *ſtring-halt*, frequently degenerates into the *ox* ſpavin; for which there is no remedy, but to apply the fire; and even this is not always ſucceſsful.

There are two other kinds of ſpavin, which have their ſeat in the hoof, *viz.* the *blood* ſpavin, which is a ſoft tumour, that grows through a horſe's hoof, and is uſually full of blood; and the *bone* ſpavin, or cruſty ſubſtance growing on the inſide of the hoof, under the joint.

SPAWDER, in *Rural Economy*, a term provincially ſignifying an injury, by the legs of animals being forced too far aſunder on ice, or ſlippery roads, &c.

SPAWN, in *Gardening*, the progeny or offspring of plants or other vegetables; but which is moſtly applied to ſuch ſmall offsets, ſuckers, and ſprouts, as riſe numerouſly from the roots, &c. of certain plants, ſerving for the purpoſe of increaſe, which, as being parts ſimilar to the whole plant, when ſeparated from the parent vegetable and planted out, readily grow, and commence proper plants, and thereby renew or increaſe their reſpective kinds with great facility and abundance. Some plants produce them in large quantities, others ſcarcely at all. (See Suckers.) And in a more general acceptation, it is likewiſe peculiarly applied to the progeny of muſhrooms, being an offspring from the root of thoſe *fungi*, conſiſting of minute white parts, ſhooting and running in the earth or dung, like ſmall white thready fibres, aſſuming the appearance of ſlender white ſtrings, which are productive of numerous minute white knobs, appearing at firſt of the ſize of ſmall pin-heads, the whole ſmelling ſtrong of the muſhroom; and thoſe little knobs being infant plants, they gradually increaſe in ſize to proper muſhrooms, which are quick of growth, and of very ſhort duration; but the ſame ſpawn running in the earth, &c. furniſhes a plentiful ſupply of muſhrooms from the bottom in regular ſucceſſion for a conſiderable time, ſometimes ſeveral months. See Agaricus.

This ſort of muſhroom ſpawn may be procured at all ſeaſons of the year, but more plentifully towards the end of ſummer and in autumn, from the places of its growth and production; ſuch as old muſhroom-beds, old horſe-dung hot-beds, and horſe-dunghills that are moderately dry, and which have remained undiſturbed ſeveral months; alſo ſometimes in old compoſt heaps, conſiſting chiefly of horſe-dung; in all of which the ſpawny ſubſtance diſcovers itſelf in dry lumps of dung and earth, which lumps ſhould be taken up entire: likewiſe in ſtable-yards, where any quantity of horſe-dung has lain dry and undiſturbed any conſiderable length of time, lumps of ſpawn are often obtained. It is alſo found in great perfection in the horſe-rides belonging to great inns, livery-ſtables, and horſe-dealers, eſpecially on the ſides next the walls; likewiſe in horſe-mill tracts, where horſes are conſtantly employed in working and dropping their dung, which is ſwept together on the ſides, there to remain; alſo in kitchen-gardens, where any piece of ground has been dunged in the ſpring with new, or but moderately rotted ſtable-dung, or old dry hot-bed dung, &c. and only ſlightly turned in, as already ſhewn under the head of making theſe beds. And ſometimes it is produced naturally all over the ſurface of an old cucumber or melon hot-bed, both in the dung and earth, in autumn or winter, where the frame and lights have been continued over the bed; and where the earth of the bed is of a loamy nature, the ſpawn in which is often remarkably fine and ſtrong; for in this kind of earth, of a moderately light quality, it is generally of a ſuperior quality, and very productive; ſo as ſometimes, in ſuch old beds, where the frames and glaſſes remain, and the ſurface of the bed is covered thickly with dry ſtraw, litter, or hay, under the glaſſes, to produce a full crop of good muſhrooms towards the ſpring. Muſhroom ſpawn is alſo obtained in meadows and paſtures towards the end of ſummer and in autumn, before the rain and cold commences, as in the months of Auguſt and September, when the muſhrooms riſe naturally, ſerving as a direction to the place where to find it; but that found in the other places is moſtly the beſt in quality. Some caution is alſo neceſſary in collecting ſpawn from fields to have it of the right ſort.

On this ſubject it is neceſſary to obſerve, that there is alſo a fruitful and barren ſort of muſhroom ſpawn; the former is diſtinguiſhed by the ſubſtance of the fibry or ſtringy white ſhoots, &c. and muſhroom-like ſmell, as before obſerved; but in the latter ſort, the thready fibres are far more abundant, fine, and downy, often appearing like a fine white down, and, being of no ſubſtance, produce only a flaſh of ſmall white fungi, deſtitute of the fleſhy part, and which, by the muſhroom-men, is commonly called *white-cup*.

Methods are ſometimes practiſed to obtain muſhroom ſpawn more abundantly by art, by the effects of horſe-dung, both in hot-beds and compoſt heaps; ſometimes, in the former caſe, by planting ſmall pieces of ſpawn, or ſpawny earth, along the top edge of the later cucumber hot-beds in ſummer, or in the ſides of any horſe-dung heaps, having a little warmth remaining; ſo that the moderate heat of the dung in the bed or heap may ſet the ſpawn a-running, ſo as ſometimes to produce a few muſhrooms in autumn, and increaſe it conſiderably for future uſe in ſpawning proper muſhroom-beds: and in the ſecond caſe, by a compoſt of dung and loamy earth together; procuring in ſpring, or early in ſummer, a quantity of freſh horſe-dung, conſiſting of plenty of ſhort ſtuff, and a due proportion of long; and caſting the whole into a heap to ferment a fortnight or a month, that the rank burning vapour may paſs away; then having ſome loamy earth, or other good ſubſtantial mould, or any ſpawny ſoil from old beds, form the dung into a long narrow ridge, mixing ſome of the earth occaſionally towards the outſide; and in a fortnight or three weeks, when the heat becomes quite moderate, covering the whole with dry long litter to defend it from the wet, permitting the whole to remain a conſiderable time, when good ſpawn will often be produced. The heaps for this uſe are beſt formed in dry ſheds, &c.

In collecting it from any of theſe places, the lumps of dung and earth in which it appears ſhould be taken up as entire as poſſible, put into a baſket, and carried into ſome dry ſhed, or other place, when the heaps are made out of doors, till wanted, or it may be immediately uſed in making the beds.

The practice of introducing this ſort of ſpawn, in a ſuitable manner, into beds properly formed and conſtructed for the reception of it, is the beſt and moſt convenient method, which has yet been found, of raiſing crops of muſhrooms in garden cultivation. The beds for this uſe are, as has been ſeen, conſtantly prepared with new freſh horſe-dung which has undergone the proceſs of fermentation, by being thrown into a heap, in order to take off the firſt violent coarſe heat, and then formed in the long narrow ridge manner, ſomewhat in the ſhape of a roof, for throwing off moiſture, and left expoſed in that ſtate until it becomes in a proper ſtate of heat, when the portions of ſpawny matter are inſerted all over the ſurface, but only juſt within it, the whole moulded over an inch or two in thickneſs, and then covered cloſely with dry litter to a proper depth. The parts of the ſpawn are conſequently planted in a ſort of hot-bed, by means of which they rapidly advance in growth, and ſoon furniſh ſupplies of good muſhrooms for uſe. The ſpawn, being forced into action in this way, is often not longer than ſix or eight weeks in producing plentifully; the ſame bed frequently continuing to afford a ſupply for five or ſix months, or longer; but new beds are to be made every year, and ſometimes two or three times in that ſpace of time, in order to furniſh a conſtant ſucceſſion of good muſhrooms. See AGARICUS, and SPAWNING *Muſhroom-Beds*.

Where there is plenty of this freſh ſtable littery dung and the ſhort ſtuff in mixture, muſhrooms are ſometimes not only abundantly ſupplied, but plenty of ſpawn for future beds.

No proper ſeed of the muſhroom has hitherto been diſcovered by which crops of it can be raiſed by the gardener, though it is well known that it produces ſeed like other plants, and is naturally produced in that way, as well as by ſpawn. The extremely minute ſeeds are ſaid, in this caſe, to be ſituated and contained in the *lamellæ* or gills, which, when full grown, and the ſeeds become quite ripe, diſcharge and diſperſe them upon the ſurrounding ground, from which they are conveyed by the wind and other means to other diſtant ſituations, where the ſoils are ſuited to their growth. In theſe they fix themſelves and grow, their roots increaſing rapidly ſo as to produce proper ſpawn.

The ſituations in which proper ſupplies of good ſpawn are to be met with, as well as the formation of it, will in ſome meaſure be ſeen from what has been ſaid. That which is produced in the horſe-dung methods is, however, conſtantly to be preferred to ſuch as is procured from the field, for all the purpoſes of cultivation in the garden, as producing thicker, firmer, more fleſhy, and richer flavoured muſhrooms. All old worn-out ſpawn ſhould, of courſe, be rejected, as improper and unfit for being made uſe of in this culture, and the new virgin ſpawn, as it is termed, or ſuch as has not been in production of muſhroom crops, be employed, as in ſome inſtances, even the young offspring ſpawn of ſuch as has been long wrought from bed to bed, will degenerate; there being not unfrequently a very material difference in the goodneſs of that which is freſh and full of heart, and that which has been long in uſe, the former producing fine and abundant crops, while the latter only ſends up a flaſh of ſmall trifling heads at firſt, of none or very little ſubſtance, and perhaps no more of any conſequence afterwards.

New littery and plenty of ſhort horſe-dung, eſpecially when mixed with a little loamy earth, are the moſt remarkably and abundantly productive of good ſpawn. When they have lain together for a conſiderable length of time, they are moſtly in a peculiarly fit ſtate for producing it in large quantities.

Spawn of this ſort keeps well when laid up cloſe in a dry place, or when put up in hampers or baſkets, and covered in a cloſe thick manner by dry litter or mats. The drier it is put up and kept within moderate limits the better, as the more it will improve in its productive properties, and take more freely in the beds when planted, retaining its vegetative qualities for many months.

As this ſort of ſpawn is of great importance and value in many places, where large quantities of muſhrooms are raiſed for ſale in the markets, certain perſons in ſuch ſituations often employ themſelves at particular ſeaſons of the year, but eſpecially in the autumn, in going about to different parts and collecting it, which near large towns moſtly pays them well, being of ready ſale at a high price, as ſix or ſeven ſhillings the buſhel, and more in ſome caſes.

When it is to be provided in the vicinity of the metropolis, it will commonly be met with in the moſt ready manner at the neat-houſe gardens on the different ſide of it, at the different markets in it, where vegetables are expoſed for ſale, and in the principal nurſery garden grounds.

It is capable of being packed up and ſent to any diſtance when neceſſary.

SPAWN, *Fiſh*, in *Rural Economy*, the oviparous or egg-like granulated ſubſtance which is depoſited by female fiſhes, in order to its being impregnated by the more liquid ſeminal matter of the males, and be thereby rendered productive of the young progeny or fry of the particular ſort or kind.

Each ſort of fiſh has its peculiar habit or economy in the performance and mode of depoſiting this material, as may be ſeen in the following article. Some ſorts of fiſh are likewiſe much more productive of it than others, conſequently more prolific. This is the caſe with the herring and the ſalmon, the former of which is only a fiſh that weighs from five to ten ounces, according to Harmer, but in which the ſpawn weighs 480 grains, and has the amazing number of 36,960 eggs, when examined about the month of October: the latter, though a much larger fiſh, is productive of ſpawn in a very high degree, the number of its ova being almoſt countleſs. And there are other ſorts of fiſh, which probably equal or out-number either of theſe, as the mackarel, ſprat, and ſome others. It is neceſſary that fiſh ſhould be as little as poſſible diſturbed at the time of their depoſiting their ſpawn in the rivers, and on the banks of the ſea-ſhores, or other places, as it may not only be prejudicial to them, but injurious in preventing the male fiſh from impregnating it in a proper manner.

SPAWNING *of Fiſh*, the act of depoſiting the raw, ſpawning, or oviparous matter of the female, and of its being impregnated by that of the male, for the purpoſe of breeding or producing their young. Moſt ſorts of river-fiſh, and many of thoſe of the ſea kind, produce their young progeny in this way. This operation or work of impregnation is accompliſhed in different manners as to the mode of its depoſition, according to the nature and habits of the fiſh, and the ſeaſons at which the ſpawning takes place. In thoſe fiſhes which ſpawn in the more ſtill and ſhallow waters during the ſpring and ſummer ſeaſons, ſuch, for inſtance, as thoſe of the pike, bream, carp, perch, and ſome other kinds, it would ſeem to be moſt commonly the habit to depoſit their ſpawny material on the leaves and vegetables which lie juſt below the ſurface of the water, which is in all probability the moſt favourable ſituation for it in different reſpects. While in thoſe fiſhes which caſt their ſpawn in the winter ſeaſon, ſuch as the ſalmon, trout, herring, and many other ſorts, ſpots and places very near the ſources or beginnings of rivers and ſtreams, or the more rapid freſh-water currents, are moſtly ſought for and fixed upon in this intention, where there is a conſtant flow of freſh water, where all ſtagnation is prevented, and where the water is the moſt fully aerated, either in its natural ſituation or during its fall in rain, as being probably the moſt ſuitable and favourable for the purpoſe. A proper and ſuitable degree of warmth may alſo be neceſſary in this buſineſs.

In all other caſes the fiſhes probably depoſit their ſpawny oviparous matters in ſuch ſituations as are the moſt ſuitable to their particular economies, and where there is the neceſſary heat, as well as where the water is the moſt fully ſaturated and impregnated with air, as it is now well aſcertained, that their impregnated ſpawny oviparous matters do not produce young ones, any more than ſeeds vegetate, except where they are freely ſupplied with air. The fiſh in the egg or ſpawn, derives its oxygen from the air which is diſſolved in the water that ſurrounds or flows over it, which, in the firſt of the above caſes, is much ſupplied to the water by the leaves of the plants on which it is depoſited, in performing their healthy functions; which alſo probably afford a better and more ſuitable ſituation for the male fiſhes impregnating it upon than any others: and in the latter caſe, it is gained from the perpetual flowings of ſuch freſh and fully aerated waters over it, after it has been the moſt conveniently and effectually impregnated in ſuch ſhallow parts, currents, and ſtreamlets. It has indeed been ſuggeſted, that in this latter caſe, it is the inſtinct leading the fiſhes to provide a proper ſupply of air for their ſpawny oviparous material, which is to be depoſited, that carries or forces them from the ſeas, lakes, and other ſimilar ſituations, into mountainous countries; and which impels and induces them to move againſt the ſtreams, as well as to endeavour and make efforts for overleaping weirs, cataracts, mill-dams, and other ſimilar erections and works. See Seed.

The ſpawning and generation of fiſh was however formerly conſidered as of a very different nature, and as being performed in a very different manner. It is ſtated, in ſpeaking of the herring, by the writer of a paper in the third volume of the "Tranſactions of the Highland Society of Scotland," that a very ſingular and ſeemingly unphiloſophical notion had been held with regard to the impregnation of the ova or eggs of fiſh, and which is not by any means the doctrine or hypotheſis of yeſterday, but which has prevailed, in a greater or leſs degree, for upwards of two thouſand years; that is, from the days of Herodotus, who in treating and ſpeaking of the fiſh in the Nile, makes the following obſervation. "At the ſeaſon of ſpawning they move in vaſt multitudes towards the ſea, the males lead the way, and emit the engendering principle in their paſſage; this the females *abſorb* as they follow, and in conſequence conceive, and when their ova are depoſited, they are conſequently matured into fry." Beloe's Herod.

And ſtrange and abſurd as this ſuppoſition and proceſs ſeem to be, it is aſſerted, it is ſaid, to be the caſe by Linnæus, the moſt learned of all others in the ſcience of animal hiſtory: he tenaciouſly affirms, it is maintained, that there can be no impregnation of the eggs of any animal out of the body, and that as fiſh have no organs of generation, that deficiency is made up for by adopting the ſyſtem or notion of Herodotus. This abſurd and unfounded notion has likewiſe, it is added, been attempted to be ſupported by Kalm, the friend and countryman of the above celebrated naturaliſt, on a ſtory ſuppoſed to have been told by Franklin about two rivers in his province (New England in North America,) which fell into the ſea nearly together; in one of which no herrings were ever taken, while in the other they were abundantly caught; the fiſh, when they come to depoſit their ſpawn, always paſſing up that river without ever entering the other. In order to try to make the fiſh take to the other river, this perſon is ſaid to have put out his nets and taken ſome of them, as they were coming up for ſpawning in the productive river. He is ſaid to have taken "the *ſpawn out of them*, and to have carefully carried it acroſs the land into the other river, where *it was hatched*, and the conſequence was, that every year afterwards they caught more herrings in that river; and this is, it is ſaid, ſtill the caſe." But on inquiry in that country, the writer of the above paper remarks, both the river and the ſtory were unknown to all who were inquired of about the matter.

The ſame ſtory is ſince ſuppoſed to have been trumped up by a French writer of the name of Nouel, with this ſtrong ſhade of difference; that the former *cuts* the ova out of the belly of the herring, while the latter ſays, that the ſpawn was collected from off plants, where it had been depoſited. At one of the ſittings of the National Inſtitute in France, in the year 1799, a memoir was read by this member of inſtruction at Rouen, on the means and advantages of naturalizing the herring, a ſalt-water fiſh, in the water of the Seine, near its mouth, &c.; in which, after noticing the various means by which this may be accompliſhed, it is obſerved, that "herrings having been found aſcending from the ſea into one river of the American province, (noticed above,) while a ſingle individual was never ſeen in another, ſeparated from the other by a narrow tongue of land, and which alſo communicated with the ſea, this philoſopher (Dr. Franklin) took the *leaves off ſome plants on which the herrings had depoſited their ova*, already fecundated, and conveyed them to the river which was deprived of the annual viſit of theſe fiſh. The ſucceſs of the experiment ſurpaſſed his expectation, the ova was completely productive, and the following year the river was peopled with a numerous ſhoal of herrings, which, ſince that time, continued to frequent it." Phil. Mag. vol. x. p. 163.

This account the writer of the above paper conſiders as evidently founded upon the former, and both, he thinks, come in a very queſtionable ſhape; however, the theory of the latter is ſuppoſed more rational, and not entirely againſt eſtabliſhed facts; though it ſhould be conſidered, he conceives, that the European herring is not a native of freſh water, and, as he thinks, never will be naturalized in ſuch waters; but that the ſpawn of fiſhes, being fecundated in their own waters, may be tranſported; and when placed in the ſame homogeneal element upon leaves, ſand, or other matters, where the ſun and air, as we have ſeen above, can have free acceſs, or a proper heat, with oxygen air, as has been ſhewn already, received, ſuch ova, raw, or eggs, will be animated and become fry in the ſame time they would have done in their parent beds, cannot be doubted. This is a practice, it is ſaid, which is well known in China; the Miſſionaries to which have noticed two or three things about it which are ſingular enough; the firſt of which is, that in the great river Yangtſe Kyang, not far from the city Kyus-king-fu, in the province of Kyang-ſi, a prodigious number of barks meet every year to buy the ſpawn of fiſhes. About May the people of the country dam up the river for nine or ten leagues together, in ſeveral places, with mats and hurdles, leaving only room enough for barks to paſs, in order to ſtop the ſpawn, which they know how to diſtinguiſh at firſt ſight, though the water is ſcarcely altered; with this water mixed with the ſpawn, they fill ſeveral veſſels to ſell to the merchants, who, at this ſeaſon, arrive in great numbers to buy and tranſport it into divers provinces, taking care to have it ſtirred up from time to time: this water is ſold by meaſure to ſuch as have fiſh-ponds and pools belonging to their houſes. The manner of propagating the gold-fiſh from ſpawn is likewiſe deſerving of attentive conſideration. Du Halde's Deſcrip. of China.

It is ſuppoſed by the writer of the paper, that herrings which caſt their ſpawn in the winter months, without doubt depoſit it on our ſhores; but whether upon gravel, ſand, ſtones, fuci, or other plants, is not well aſcertained; but thus far we know, it is ſaid, that it cannot be in deep water, unleſs we ſuppoſe it to have ſuch a buoyancy as to be within reach of the ſun's genial influence, and, as has been ſince ſhewn, that of the free action of the air.

It is believed, and the ſame writer thinks with reaſon, that it is impregnated by the male after it is emitted by the ſpawner or ſpawning-fiſh. The raw ſpawn, or eggs, of theſe fiſh, become animated, it is ſaid, in the month of April. It is noticed, that the *fucus palmatus*, and indeed all the numerous ſpecies of fuci which grow upon our coaſts, it is hardly to be doubted, harbour the ſpawn of fiſhes; but that the opinion may readily be either confirmed or confuted by the aſſiſtance of a glaſs of moderate magnifying power.

It is ſuggeſted, likewiſe, that the cauſe or reaſon of the herring's quitting the deep ſeas, is unqueſtionably that of its caſting its ſpawn in its native water, as the banks and mouths of the rivers where it was produced. And the ſame is the caſe with the ſalmon, the ſhad, the pilchard, and ſome others; all of which prefer their natal waters for the purpoſe of ſpawning in; and though the herring and pilchard ſometimes deviate from this courſe, the ſalmon and ſhad do it very ſeldom, being more ſober and ſteady in their attachment to their parent haunts. The heavieſt ſalmon are met with in the large rivers, and the largeſt herrings in the deep waters, each coaſt and river producing fiſh which are different in taſte, ſize, and appearance, as is remarkably ſeen in the ſhads and ſalmons of different rivers, and the herrings of different ſituations. The fry of the herring, as well as of the ſalmon, when they have attained ſufficient ſize and ſtrength, quit the ſhallows and make for the deeps: when the ſhoals of the former enter the bays, and other ſimilar places, the young ones are noticed to take their final departure from them.

The fecundity of different kinds of fiſhes is very different; but that of the herring and ſome others is very great. See Spawn, *Fiſh*.

Spawning or *Laying Oyſter-Beds*, the manner of preparing, diſtributing, and managing them, in the mouths of the breeding-rivers in particular counties and diſtricts, as in Eſſex, and probably ſome others. The exact method of performing the buſineſs has not been deſcribed; but they are ſpawned or laid ſomewhat in the bed-manner. The principal rivers in the county of Eſſex, where this ſort of work, or that of breeding oyſters, is carried on, according to the Corrected Agricultural Report of that diſtrict, are thoſe of the Crouch, the Blackwater, and the Coln; but the firſt is by far the moſt certain in produce of any of them. The beds, or layings, are made in the creeks, and other ſimilar places, on the ſides or parts which adjoin the mouths, openings, or beginnings of theſe rivers. It is from theſe rivers that the oyſter-layings, or beds, are uſually ſtocked; though ſome are conſtantly ſupplied from Portſmouth, or places in its neighbourhood, being brought in the largeſt ſort of oyſter-veſſels, not only into this county, but Kent, where they are laid for the enſuing ſeaſon. The Colcheſter oyſter-beds are chiefly at Wivenhoe, being partly ſupplied by the Kentiſh oyſter-ſmacks. The beds, or layings, in theſe different ſituations, are likewiſe, in all probability, ſupplied or furniſhed with oyſters from ſeveral other places on the ſouthern coaſt of this country, as well as the northern one of France.

The breeding-rivers in the county of Eſſex are ſaid to be very uncertain as to the quantity of oyſters they produce; as in ſome ſeaſons they afford a great quantity, while at other times they only produce what is called a good ſprinkling, and ſometimes there is none at all. But they ſeldom all produce or fail, it is obſerved, in the ſame ſeaſon. See Oyster and *Oyſter*-Fishery.

The oyſter-fiſheries, in different places, are of very great importance to the country at large, as well as to particular counties and diſtricts, eſpecially that of Eſſex; as they employ great numbers of ſmall veſſels, require the labour of many men, and afford conſiderable profit in the produce of food which they ſupply, as being principally an article of luxury. In the county juſt mentioned there are ſeveral of theſe oyſter-fiſheries. In the Blackwater river and neighbouring parts, there is a conſiderable fiſhery of this nature; and Weſt-Merſea is one of the principal ſtations of the dredgers: above thirty boats, it is ſaid, belong to the iſland, and are almoſt conſtantly at work in this buſineſs. Veſſels come from Kent to purchaſe the oyſters, and they ſell ſome to Wivenhoe, where what are called the Colcheſter beds are ſituated. They are ſold by the tub of two buſhels, and are generally from 4*s.* to 6*s.* a tub; but at preſent (1807) 6*s.* A dredging-boat is from fourteen to thirty or forty tons burthen: all are decked and built at Wivenhoe, Brightlingſea, and places thereabouts. The price is 10*l.* a ton for the hull of the veſſel only; the fitting out of one of twenty tons requiring the amount of 150*l.* From two to four men are required for each veſſel, who are paid by ſhares; and the maſter has a ſhare for the veſſel. In the ſpring ſeaſon they go to dredge on the coaſts of Hants and Dorſet. Sometimes one hundred and thirty veſſels have been counted at work within ſight of Merſea. This oyſter-fiſhery is, it is ſaid, an object of conſiderable conſequence to the country, from the earnings being great, and ſome other circumſtances: but when the men die, their families, it is ſaid, come to the pariſh, greatly increaſed by the number of apprentices which they have taken. Nothing, however, the writer of the report thinks, can be ſo prepoſterous as a police of the poor, which permits the benefits of commerce and manufactures to load the land with rates to the amount of 8*s.* in the pound, when a very ſmall contribution by a box-club, or benefit ſociety, would readily prevent the evil. See SOCIETIES, *Friendly*.

The following intereſting account of the oyſter-buſineſs in the ſame diſtrict, is from Mr. Bennet Hawes of Merſea, given as from his own local knowledge of the places where it is carried on, in the above report. The number of veſſels which are employed in it, of from eight to forty or fifty tons, is nearly two hundred, in which are employed from four hundred to five hundred men and boys. A veſſel carrying three men has one ſhare and a half of all the earnings, and the men one ſhare each. Large veſſels have generally, it is ſaid, two ſhares; but none, it is believed, more than this.

It is ſaid that the veſſels which are built at Eaſt Donyland, Wivenhoe, Brightlingſea, Burnham, and Merſea, for this buſineſs, will laſt from thirty to forty years, when proper care is taken of them. The writer was informed by a perſon then living at Wivenhoe, that he had, within the laſt twenty years, built one hundred veſſels for the oyſter buſineſs alone.

There has been an increaſe of boats, and of courſe of men, of more than one half within the laſt thirty years.

At Burnham they have ſeven dredging ſmacks, belonging to the company that hire the river of ſir Henry Mildmay, beſides four other private ones, and ſome ſmaller veſſels. The ſmacks are from eighteen to twenty tons. And there are only about one hundred fiſhermen and ſailors about the place, which are much too few, it is thought, for ſo fine a river.

Moſt of the veſſels of ſixteen tons and upwards, go, it is ſaid, to Portſmouth, or places adjacent, in the month of March, to catch and carry oyſters; thoſe under twenty-five tons being employed in catching them, and the larger ones in carrying them into this county and Kent, to be uſed as noticed above; they generally return from thence in the month of June, when the large ones go after mackarel, herrings, and ſprats, during the latter part of the ſummer, and in the enſuing winter, the ſmaller ones to the catching of oyſters in the breeding rivers, as above.

The oyſters are ſold to London, Hamburgh, Bremen, and, in time of peace, to Holland, France, and Flanders.

The price has varied but little for theſe laſt ten years.

The quantity conſumed in a ſeaſon is ſcarcely to be calculated; but it is ſuppoſed that it cannot be leſs than 12,000 or 15,000 buſhels.

This ſort of fiſhery is ſo much blended with the others, that it is almoſt impoſſible to ſtate the capital which is employed in it, but it is ſuppoſed to be from 60,000*l.* to 80,000*l.*

SPAWNING *Muſhroom-Beds*, in *Gardening*, the practice of planting or putting the muſhroom ſpawn into the beds or ridges formed for raiſing crops of this ſort. It is performed in ſeveral different manners, as by putting it into the dungy matter immediately below the ſurface of the beds, which is called ſpawning in the dung; by depoſiting it upon the ſurface of the dung, which is termed ſpawning on the ſurface; and by placing it in the mould by which the beds have been previouſly covered, which is denominated ſpawning in the earth. In all theſe modes of performing the work of ſpawning the beds, they are afterwards to be earthed or moulded over in a neat even manner, with finely reduced rich, loamy, mellow, dry, mouldy earth, ſo as to perfectly cover in the planted ſpawny ſubſtance, this being done in the two firſt methods of planting, to a much greater depth than in the laſt mode, where an earthy coat, or caſing, has been before ſupplied; an inch and a half, or two inches in depth of mould, being neceſſary in the former caſes, while an inch or leſs may be fully ſufficient in the latter caſe. The ſpawn is properly divided into pieces, and put into the beds in all theſe modes in a regular manner, at narrow diſtances, both in the rows and ſpaces between them, as about ſix or ſeven inches in each, over the whole of the different ſides and ends of them. There is little difference in theſe modes of putting in the ſpawn, except that in the two firſt, and eſpecially in the ſecond, it can be laid in rather more cloſely than in the laſt, by which means, ſometimes, a more forward and plentiful ſupply of muſhrooms is produced.

After the earthing has been properly accompliſhed in theſe different caſes, the beds are ready for the reception of the ſtraw coverings, as no light is ever requiſite in the growth of theſe crops. Theſe ſtraw coverings ſhould invariably be applied as ſoon as ever the ſtate of the beds, in regard to the heat they produce and retain, will permit, after the ſpawning of them is finiſhed. It ſhould be done to a conſiderable thickneſs, eſpecially where the beds are not in ſheds, but expoſed to the effects of the weather, in order to afford the ſpawn a proper degree of heat and full protection. Such ſtrawy littery materials may be gradually ſhook upon them, from the thickneſs of half a foot, to ſuch depths as are ſufficient to produce a ſuitable warmth for promoting the growth of the ſpawny material. They are to be lightly and regularly ſhaken on over the whole, and to remain conſtantly, having in ſome caſes other ſorts of coverings laid over them, as no ſort of moiſture muſt come near the ſpawn in theſe caſes.

As little expoſure to the full air as poſſible, after ſpawning the beds, ſhould take place in performing any ſort of work about them, as there is much injury and check produced by it in the growth of the ſpawn, and, of courſe, in the crops to be raiſed by it.

The proper running and knitting of the ſpawn, which may be ſeen by turning up a little of the ſtrawy coverings, ſhews the ſpawning of the beds to have been ſucceſsfully performed; but this ſhould not be judged of too haſtily, as this ſort of ſpawn is ſometimes ſlow in coming into an active ſtate of vegetation. There is alſo a fine full ſmell of the muſhroom in all ſuch caſes. See AGARICUS.

SPAWS, mineral waters ariſing out of the earth; impregnated with nitre, ſulphur, alum, bitumen, copperas, or other mineral matter, in paſſing through the ſtrata thereof; and hence endued with ſome medicinal qualities, cathartic, diuretic, emetic, alterant, or the like. See *Mineral* WATERS and SPA.

SPAX, a name given by ſome authors to the common tænia, a ſmall fiſh of the anguilliform kind, frequent on the ſhores of Italy.

SPAYING, in *Rural Economy*, the operation of cutting, caſtrating, or removing the female parts of different kinds of animals, as ſows, heifers, mares, &c. in order to prevent any future conception, and promote their fattening. It is uſually performed by cutting them in the mid-flank, on the left ſide, with a ſharp knife or lancet, in order to extirpate or cut off the parts deſtined to conception, and then ſtitching up the wound, anointing the part with tar-ſalve, and keeping the animal warm for two or three days. The general way is to make the inciſion in a ſloping manner, two inches and a half long, that the fore-finger may be put in towards the back, to feel for the ovaries, which are two kernels as big as acorns, one on each ſide of the uterus, one of which being drawn to the wound, the cord or ſtring is cut, and thus both taken out.

It may be noticed, that in the Annals of Agriculture, Mr. Foot has ſuggeſted the practice of ſpaying old cows and heifers; as it is a method, he apprehends, that might be performed with ſafety, and prove of general uſe in grazing; as cows, when they grow old and fail in their milk, are often attended with difficulty, where the bull goes at large, to keep them from him, eſpecially on commons, during the ſummer, which put him on trying the experiment on a cow of ſmall value, whoſe profit for the pail was ſo far over, that ſhe would not milk for about three months before ſhe became dry. After ſhe had calved about a month, he had her cut; the operator was an ingenious perſon, and performed the buſineſs well, that with a little care of keeping her from the cold (being early in the ſpring) for about a fortnight he thought her out of danger; and continued milking her as uſual all the time. She ſoon began to thrive, gaining fleſh, and before the ſummer was over, by the time ſhe was quite dry, was much improved, though kept no better than the other part of the dairy on very middling paſturage. At Michaelmas, had ſhe been put to turnips, or good rouen, ſhe would have been fat by Chriſtmas, or ſoon after. When killed, ſhe ſold at 3*s.* 6*d.* a ſtone, about half fat at that time, which he laid at one ſhilling a ſtone more than ſhe would have done had ſhe not been cut. And afterwards he had two others cut, that continued to be milked, and grazed well; one he had killed, the other he ſold alive, which improved and paid beyond expectation. And though little has yet been done in this way, he is perſuaded it will be found of general utility, if attended to. But, however, lately he accidentally met the perſon that performed the operation, who informed him that he had been ſent for within twelve months, or thereabouts, to cut near forty in like manner, which having all done well, none failed; that there appears little or no danger in the caſe; and he believes it may be found of great advantage to the grazier and farmer, if they are inclined to practiſe it, as well as to the public at large. In confirmation of the above, the perſons who have tried the experiment are, he is informed, William Colhoun, eſq. Norfolk, who has cut eight; Mr. Martin, Exning, Suffolk, who has cut ſix; Mr. Cayſon, Chippenham, who has had the operation performed on twenty; and Mr. Robinſon, Eriſwell, who has performed it on four or ſix.

And he may further add, that moſt of theſe were young heifers between two and three years old (ſome old cows), that had not taken bull; the young ſtock appears to thrive apace, and grow in ſize, as well as to be likely to anſwer for the butcher ſoon; they may be fattened with turnips in the winter, or kept on another ſummer, as the grazier pleaſes. And in Yorkſhire it is very common to fatten their heifers at three years old, which anſwer as great a purpoſe for grazing, and are more profitable than older ſteers or heifers, &c. but thoſe are kept from the bull.

Farther, although there is a method generally practiſed in ſpaying calves that are intended for heifers of that name, which are uſually cut about ſix weeks or two months old, yet this other method of treatment, he thinks, is preferable and not ſo dangerous, for the two-years old beaſts may be ſuppoſed ſtronger and more fit to undergo the operation; and, in the next place, it is performed quite differently; what is cut away, is only the ends of what is termed the *luſts*, or generative parts, which are not, when ſeparated from the other parts, bigger than the end of a man's thumb to the firſt joint, that makes the operation leſs painful and dangerous when rightly performed. But he would not adviſe every butcher, or inexperienced artiſt, to undertake what they do not underſtand. He thinks this obſervation is due to the operators, who have cut upwards of forty head of cow-ſtock in this manner, (as they informed him,) which have all done, and are doing, well, and he recommends them to public encouragement in an art that is likely to be attended with general utility to the public. They are William Bailey and ſon, Lakenheath, Suffolk. He may further obſerve, that a heifer at two or three years old may be defective in the bag, in the loſs of teats, or thoſe of ſmall ſize, not larger than an ewe's, which ſeldom are profitable for the pail, which may be cut after this mode and grazed.

And Mr. Marſhall, in his Rural Economy of Yorkſhire, remarks, that it is a fact well eſtabliſhed in the common practice of that diſtrict, that ſpayed heifers work better, and have, in general, more wind, than oxen; and it is not doubted that ſpayed mares would have an equal preference to geldings. The reaſon held out againſt this practice, though formidable at firſt ſight, proves a mere ſhadow on examination. The ſpaying of fillies would undoubtedly ſpoil them for brood mares. But does not the gelding of a colt ſpoil him for a ſtallion? What breeder, when his mares foal, wiſhes for fillies? and what dealer would not give 2*s.* 6*d.* for each, to have his mares changed into geldings, or perhaps into animals ſuperior to geldings? Beſides, in the ſpring of the year, open mares are faint and troubleſome. The only requiſites appear to be a ſafe cutter, and a man of ſpirit to ſet him to work, to bring the ſpaying of female foals into common practice; and it does not follow that, becauſe a part of the female foals ſhould be cut, there would not be open mares to breed from; more than it does, that becauſe ſome heifers are ſpayed for the yoke, or for fattening, there are not cows ſufficient for the purpoſes of breeding, and the dairy. He does not mean, however, to recommend a practice of which he has had no experience; but if the experiment has not been tried, it ſtrikes him forcibly, that it is worth the trial; and that it is more than time it were ſet about. Since this, he however ſtates, that it had been tried in the ſouthern diſtricts, as he ſaw a mare in 1791, then riſing five or ſix years old, which had been ſpayed at eight days old by a colt-cutter in the neighbourhood of Petworth; and that ſhe was a well-bred mare, and of a ſize proper for hunting. The farmer to whom ſhe belonged aſked ſeventy guineas for her, a proof that in his eſtimation, at leaſt, ſhe had not been injured by the operation. And it is probable, that this practice had been attempted long before that period. See CATTLE.

There can be no doubt but that the notion of injury being done by the ſpaying of female animals is wholly erroneous, and without any foundation in truth or correct obſervation, as the experience of every day ſhews it to be ſo in the moſt full and ſatisfactory manner. The chief reaſon why a practice, which is beneficial in ſo many points of view to the intereſts and advantages of the farmer, has been ſo little attended to, is the difficulty which is conſtantly experienced from the want of a ſufficient number of expert and proper perſons for performing the operation. Such perſons are far from being common in any, much leſs in every diſtrict, as ſome knowledge of a nature which is not readily acquired, and much experience in the practice of cutting, are indiſpenſably neceſſary to the ſucceſs of the undertaking. Whenever, however, the utility and benefits of the practice become better underſtood and more fully appreciated by the farmer, and the operators more numerous, much greater attention and importance will be beſtowed upon it, as it is capable of relieving him from much trouble, of greatly promoting his profits, and of benefiting him in a variety of ways. The facts are long ſince well proved and aſcertained, that animals which have undergone this operation, are more diſpoſed to feed or take on fleſh, more quiet in their habits, and capable of being managed with much greater eaſe and facility in any way whatever, than they were before it was performed. It may alſo have advantages in other ways, in different ſorts of animals; it may render the filly, in the horſe kind, nearly equal to the gelt colt for ſeveral different uſes; and the heifer, in the neat cattle kind, nearly equal to the ox, for all ſorts of farm-labour. The females of ſome other ſorts of animals may likewiſe, by this means, be made to nearly equal the caſtrated males in uſefulneſs for a variety of purpoſes and intentions; and in all caſes be rendered a good deal more valuable, or manageable, than they are in the preſent cuſtom which prevails with them.

Spaying *of Fiſh*. See *Caſtration of* Fish.

SPEAKER *of the Houſe of Commons*, a member of the houſe, elected by a majority of the votes, to act as chairman, or preſident, in putting queſtions, reading briefs or bills, keeping order, reprimanding the refractory, adjourning the houſe, &c.

The firſt thing done by the commons upon the firſt meeting of a parliament is to chooſe a ſpeaker, who is to be approved of by the king; and who, upon his admiſſion, begs his majeſty, that the commons, during their ſitting, may have *free acceſs to his majeſty*, *freedom of ſpeech in their own houſe*, and *ſecurity from arreſts*. See Parliament.

The ſpeaker is not allowed to perſuade, or diſſuade, in paſſing of a bill, but only to make a ſhort and plain narrative; nor to vote, unleſs the houſe be equally divided. The lord chancellor, or keeper, or any other appointed by the king's commiſſion, is uſually *ſpeaker of the houſe of lords*; and if none be thus appointed, the houſe of lords (it is ſaid) may elect. The ſpeaker of the houſe of lords, if a lord of parliament, may give his opinion, or argue any queſtion in the houſe.

The *ſpeaker of the convocation* is called *prolocutor*.

Speaker is uſed by *rhetorical* writers in the ſame ſenſe with orator. See Oratory. See alſo Elocution, Pronunciation, and Action.

As to the character and addreſs of an orator, it is neceſſary that every thing appear eaſy and natural, and the diſpoſition of the ſpeaker be diſcovered by his words: thus would he expreſs what Quintilian calls a propriety of manners: accordingly, the ancient rhetoricians made it a neceſſary qualification in an orator, to be a good man; ſince he ſhould always be conſiſtent with himſelf, or, as we ſay, talk in character. There are four qualifications more eſpecially ſuited to the character of an orator, which ſhould always appear in his diſcourſes, in order to render what he ſays acceptable to his hearers; theſe are wiſdom, integrity, benevolence, and modeſty. See an illuſtration and inforcement of them in Ward's Orat. vol. i. lect. 10.

SPEAKING, the art, or act, of expreſſing one's thoughts in articulate ſounds or words.

Pliny, Ælian, Plutarch, and other authors, make mention of ſeveral beaſts that have ſpoken: and Pliny himſelf ſpeaks with aſſurance, in his hiſtory, of an ox that ſpoke. Philoſtratus, in his life of Apollonius, gives the like quality to an elm, and even to ſhips. Homer makes Xanthos, one of Achilles's horſes, ſpeak; in which he has been followed by Oppian. But theſe are all fabulous ſtories; we have much better authority for a ſerpent and an aſs's ſpeaking, unleſs the caſes here referred to be allegorical. See Language.

Speaking-*Trumpet*. See Trumpet, and Stentorophonic.

SPEAN, in *Geography*, a river of Scotland, which forms a communication between loch Laggan and loch Lochly.

SPEAR, in *Armoury*. See Lance.

Spear, in the *Manege*. The feather of a horſe, called the *ſtroke of the ſpear*, is a mark in the neck, or near the ſhoulder of ſome Barbs, and ſome Turkey and Spaniſh horſes, repreſenting the blow or cut of a ſpear in thoſe places, with ſome reſemblance of a ſcar. This feather is an infallible ſign of a good horſe.

Spear-*Hand*, or *ſword-hand* of a horſeman, is his right hand.

Spear-*Foot*, of a horſe, is the far-foot behind. See Far.

Spear, *King's*, in *Botany*. See Asphodelus.

Spear-*Thiſtle*, in *Agriculture*, a plant of the weed kind, which is often troubleſome in land. It is a biennial, and of courſe readily deſtroyed by taking care to have it mown down or cut over before the time of its perfecting its ſeeds. It is not unfrequently termed the bur-thiſtle.

SPEARMINT, in *Botany*. See Mentha.

SPEARWORT, the Engliſh name of the ranunculus flammeus.

This is with us generally eſteemed a poiſon, but the Scots uſe it as a medicine. They beat it, and ſqueeze out the juice, which they take as a purge, drinking a little melted butter or oil before and after it, to prevent its taking the ſkin off from the throat. It operates very violently, but with robuſt conſtitutions it does very well.

They uſe it alſo externally in caſes of pain in the head, or any other part of the body. They bruiſe the leaves to a ſort of paſte, and apply them to the part; they ſoon raiſe a bliſter, and a large quantity of water is diſcharged, after which the pain goes off. This is a ſhort way of bliſtering, and anſwers as ſafely and as well as our's by the cantharides: but it is a wonder that people, who ſee this quality in the plant, ſhould dare to take it into their mouths and ſtomachs.

Spearwort is very prejudicial to ſheep, as cauſing the rot. It is alſo troubleſome in lands of the more wet kinds.

SPECIA, in *Geography*, an iſland in the Grecian Archipelago, about 10 miles in circumference, at the entrance of the gulf of Napoli. N. lat. 37° 15′. E. long. 23° 23′.

Specia *Poulo*, a ſmall iſland near the ſouth coaſt of Specia.

SPECIAL, ſomething that is particular, or has a particular deſignation; from the Latin *ſpecies*: in oppoſition to *general*, of *genus*. See General, Particular, Species, and Genus.

The king, in his letters, frequently ſays, of our ſpecial grace, full power, and royal authority.

Special *Aſſiſe*, *Attorney*, *Bail*, *Caſe*, *Fee-tail*, *Iſſue*, *Jury*, *Plea*, *Seſſion*, *Statute*, *Verdict*, and *Warrant*. See the articles.

SPECIALTY, in *Law*, is moſt commonly taken for a bond, bill, or other inſtrument in writing. Accordingly, debts by ſpecialty, or ſpecial contract, are ſuch by which a ſum of money becomes, or is acknowledged to be, due by deed or inſtrument under ſeal: ſuch as by deed of covenant, by deed of ſale, by leaſe reſerving rent, or by bond or obligation. Theſe are looked upon as the next claſs of debts after thoſe of record, being confirmed by ſpecial evidence under ſeal.

SPECIE, in *Commerce*, gold and ſilver coin, diſtinguiſhed from paper-money; but in Germany, the word ſpecie is applied to the rix-dollar, and its diviſions, as coined after the rate of the empire.

SPECIES, an idea, which relates to ſome other more general one, or is compriſed under a more univerſal diviſion of a genus; as in the definition of any thing, we obtain its general nature or genus, by comparing it with other things that are moſt like to itſelf, and obſerving wherein its eſſence or nature agrees with them; ſo we obtain the eſſential or ſpecific difference, by conſidering the moſt remarkable and primary attribute, property, or idea, in which this differs from thoſe other things that are moſt like it: and this attribute, or ſpecific difference, diſtinguiſhes each ſpecies from one another, while they ſtand ranked under the ſame genus.

The word is Latin, formed from the ancient verb *ſpecio, I ſee;* as if a ſpecies of things were a collection of all the things ſeen at one view.

Species is a mere term of relation: and the ſame idea may be a ſpecies, when compared to another more general one; and a genus, with regard to a more particular one. Thus body is a genus, with regard to an animate and inanimate body; and a ſpecies, with regard to ſubſtance.

The laſt ſpecies is that which can only be divided into individuals.

Animal is a ſpecies, with regard to body; and man is a ſpecies, with regard to animal. God deſtroyed mankind by the deluge; but he preſerved the ſpecies.

SPECIES, in *Logic*, is one of the five words, called by Porphyry, *univerſals.*

SPECIES, in *Rhetoric*, is that which comprehends under it all the individuals of the ſame nature. From hence, we may argue; he is a man, therefore he has a rational ſoul. And orators ſometimes take occaſion to deſcend from the theſis or genus, to the hypotheſis or ſpecies; that is, in treating upon what is more general to introduce ſome particular contained under it, for the better illuſtration of the general.

SPECIES, in the *Ancient Muſic*, denotes a ſubdiviſion of one of the genera.

The genera of muſic were three, the enharmonic, chromatic, and diatonic; the two laſt of which were variouſly ſubdivided into ſpecies: nor was the firſt without ſpecies, though thoſe had not particular names, as the ſpecies of the other two had. Theſe ſpecies were alſo called the *chroai*, colours of the genera. See GENUS.

SPECIES is alſo applied, by ancient muſicians, to the different diſpoſitions of the tones and ſemitones in a fourth, fifth, or octave. Hence they ſay there are three ſpecies of fourths, four of fifths, ſeven of octaves. Wallis's Append. Ptolem. Harm. p. 171.

The Grecians expreſſed this ſenſe of the term ſpecies by ειδος, or by σχημα. The Latin word, *figura*, has alſo been taken in the ſame ſenſe. Ariſtox. p. 6, 74. Ed. Meib. Wallis, ibid. p. 170.

SPECIES, in *Optics*, the image painted on the retina by the rays of light reflected from the ſeveral points of the ſurface of an object, received in at the pupilla, and collected in their paſſage through the cryſtalline, &c.

Philoſophers have been in great doubt, whether the ſpecies of objects, which give the ſoul an occaſion of ſeeing, are an effuſion of the ſubſtance of the body; or a mere impreſſion which they make on all ambient bodies, and which theſe all reflect, when in a proper diſtance and diſpoſition; or, laſtly, whether they are not ſome other more ſubtile body, as light, which receives all theſe impreſſions from bodies, and is continually ſent and returned from one to another, with the different figures and impreſſions it has taken. But the moderns have decided this point by their invention of artificial eyes, in which the ſpecies of objects are received on a paper or linen cloth, in the ſame manner as they are received in the natural eye. The ancients have diſtinguiſhed the ſpecies, by which objects become viſible, into *impreſſæ* and *expreſſæ.* The former are ſuch as come from without, or are ſent from the object to the organ; ſuch are thoſe we have already been ſpeaking of. And the latter are thoſe, on the contrary, which proceed from within; or that are ſent from the organ to the object.

Le Clerc, in his ſyſtem of viſion, by one of thoſe revolutions very frequent in philoſophical opinions, has called upon the ſtage again the ſpecies *expreſſæ* of the ancient philoſophers. For, according to him, it is not by ſpecies or images impreſſed on the optic nerve, that the ſoul ſees objects; but by rays, which ſhe herſelf directs to them, and which ſhe uſes as a blind man does his ſtaff, to grope out objects.

The Peripatetics account for viſion, from a kind of *intentional* ſpecies, thus: every object, ſay they, expreſſes a perfect image of itſelf on the air next to it. This expreſſes another leſs one on the air next to that; and this a third ſtill leſs. Thus are the images continued from the object to the cryſtalline, which theſe philoſophers hold the principal organ of ſeeing. Theſe they call *ſpecies intentionales;* and to account the better for their generation, they affirm, that objects exhibit them in the ſame manner, as mirrors do a man's face. See VISION.

SPECIES, in *Theology*, denote the appearances of the bread and wine in the ſacrament after conſecration. Or, as the Romaniſts define them, the accidents remaining in the bread and wine, by which they become ſenſible to us, after their ſubſtance is deſtroyed.

The ſpecies of the bread, &c. are its whiteneſs, quantity, figure, friableneſs, &c. Of wine, its flavour, quickneſs, ſpecific gravity, &c.

The generality of Romiſh divines hold, that the ſpecies are abſolute accidents. And the Carteſians, who are bound to deny any ſuch things as abſolute accidents, are greatly puzzled to explain the ſpecies, without incurring the cenſure of hereſy. F. Magnan is forced to aſſert, that the ſpecies are mere deluſions and appearances, which God impreſſes on our ſenſes.

SPECIES, in *Commerce*, are the ſeveral pieces of gold, ſilver, copper, &c. which, having paſſed their full preparation and coinage, are current in public.

SPECIES, *Decried*, or *cried down*, are ſuch as the ſovereign has forbidden to be received in payment.

SPECIES, *Light*, are thoſe which fall ſhort of the weight preſcribed by law.

The weights of the current coins, as coined, are now as follow; the ſtandard of gold being 3*l.* 17*s.* 10½*d. per* oz. the mint price of gold; and the ſtandard of ſilver being 5*s.* 2*d. per* oz. mint price of ſilver.

		dwt.	grs.
Gold,	guinea	5	9½
	half-guinea	2	16¾
Silver,	crown	19	8½
	half-crown	9	16¼
	ſhilling	4	20
	ſixpence	2	10

The current weight of gold:

	dwt.	grs.
Guinea	5	8
Half ditto	2	16

Under this weight no gold was allowed to paſs by proclamation.

Species, *Falſe*, are thoſe of different metal or alloy from what they ſhould be, &c.

Species, in *Algebra*, are the ſymbols, or characters, by which quantities are repreſented.

Species *Aromaticæ*, a new name given in the late London Diſpenſatory to the compoſition uſually called *ſpecies diambræ*. The College obſerved, that the intention of this medicine was beſt anſwered, by compoſing it of ſuch ſpices as the daily experience of the table ſhews were moſt grateful to the ſtomach, and by avoiding all ingredients which, though of the aromatic kind, are accompanied with any thing nauſeous and diſguſtful in their flavour; and, therefore, have ordered it to be now made in the following manner. Take cinnamon two ounces, cardamom-ſeeds, ginger, and long pepper, of each an ounce; make all together into a fine powder.

Species *e Scordio*, the ingredients of the diaſcordium electuary in a dry form. The recipe is ſomething altered in the late London Pharmacopeia, and ſtands thus: take bole armenic, four ounces; ſcordium, two ounces; cinnamon, an ounce and half; ſtorax, roots of tormentil, biſtort, gentian, dittany of Crete, galbanum, and gum arabic and red roſes, each an ounce; long pepper and ginger, each half an ounce; opium, three drachms; this may be left out at pleaſure; and all are to be beat to a fine powder.

Species, in *Gardening*, has ſome which conſiſt only of one, as the flowering ruſh, the hop, and ſome more; while in others they are numerous, as in the ſun-flower, the geranium, the honeyſuckle, the willow, and a great many more. There is often, too, ſome degree of ſimilarity in the culinary or domeſtic and economical uſes, as well as the medicinal properties, in the ſpecies of cultivated garden and other plants, which belong to the ſame genus or family, as in the caſes of garlick, onion, leek, ſhallot, and chives; cabbages, ſavoys, brocoli, and cauliflower; parſley and celery; the bay-tree, benjamin-tree, ſaſſafras, and cinnamon; mugwort, wormwood, tarragon, and ſouthernwood: and the ſame takes place in many other inſtances.

The ſpecies likewiſe, in ſome caſes, ſerves to denote the mode of culture and management which are neceſſary in the raiſing and growing of different plants, in the garden manner, as well as their habits of growth and production.

Species *of Plants*, in *Syſtematic Botany*, appear, as far as can be aſcertained from the univerſal experience of thoſe who are converſant with them, as well as from every thing that can be gathered from the records of remote antiquity, to remain diſtinct from each other, marked by their appropriate characters and qualities, and renewing themſelves periodically by ſexual generation. Such being the caſe with all the plants of which we have any knowledge, we conclude it to be ſo with the reſt, as well as with animals. The White Blackbird of Ariſtotle ſtill inhabits the Cyllenian groves and copſes of Arcadia, undiſturbed by the revolutions of two thouſand years; and we doubt not that the banks of the Alpheus have been fringed with the ſame violets and primroſes, through uncounted ages, as thoſe with which they are now, every ſpring, adorned.

Various plants indeed, and eſpecially domeſtic ones, like domeſtic animals, are found liable to ſome variations of colour, luxuriance, and ſenſible qualities, which have led curious inquirers to doubt whether any ſpecies are certainly permanent. This doubt could ariſe only from a ſlight view of the ſubject. Whatever caſual aberrations there may be in the ſeminal offspring of cultivated plants; a little obſervation will prove how tranſient ſuch varieties are, and how uniformly their deſcendants, if they be capable of producing any, reſume the natural characters of the ſpecies to which they belong. Nothing can better exemplify this fact, than the ſeries of experiments inſtituted, on a moſt extenſive ſcale, upon the Apple-tree, by the celebrated preſident of the Horticultural Society, Mr. Andrew Knight. They prove that every thing but ſexual propagation is only the extenſion of an individual, whoſe corporeal frame has but a certain limited exiſtence; the period of which is indeed much longer in ſome varieties than in others; and hence the valuable Golden-pippin and Nonpareil have enriched our orchards for a long courſe of years, while numerous new varieties of apples are found to endure but for a few ſeaſons. Some, however, promiſe to be more laſting, and to ſupply the place to our deſcendants, of thoſe kinds, of which we can tranſmit to them only the names. When varieties originate in the croſs impregnation of plants of different ſpecies, they partake of the inability to procreate which belongs to mule animals, and are moreover ſeldom capable of being long increaſed by cuttings, budding, or other methods. For confirmation of this, ſee the article Pelargonium.

The technical diſcrimination of the ſpecies of plants, but vaguely and ſuperficially attended to by the ancients, makes an intereſting part of the philoſophy of modern botany, which conſiders their differences as indiſputably founded in nature, and for the moſt part extends that opinion, even to thoſe aſſemblages of ſpecies which we term *genera*. On this ſubject the reader may conſult the article Genus.

Although the diſtinctive characters of genera are wiſely limited, by the moſt philoſophical botaniſts, to the parts of fructification, thoſe of ſpecies are allowed to be taken from any part of the plant. Some characters are found more important or conſtant in one tribe, others in another; none are abſolute, or invariably conſtant, in any. Number, which in the natural orders of *Caryophylleæ* and *Roſaceæ* will ſometimes afford even a generic diſtinction, in others, and even in what regards the ſtamens of the *Caryophylleæ* themſelves, will hardly be found to limit a ſpecies. The differences between ſimple or compound leaves, entire or indented, oppoſite or alternate ones, are uſually ſtriking and unchangeable; but exceptions may be found to all theſe. Colour of flowers is, on the other hand, ſeldom to be relied on as a ſpecific difference. It appears ſo in *Meſembryanthemum*, but to prove it the ſpecies muſt be cultivated from ſeed. Yet the yellow diſk of a compound flower has never been known to change hues with its blue or white radius, nor does ſuch a variation ſeem within the bounds of poſſibility. Pubeſcence is found variable both in ſtructure and quantity; but leſs, or not at all, ſo in direction. Hence the ſpecific characters of *Menthæ*, and more recently of the genus *Myoſotis*, have been determined better than by any other means.

The infloreſcence, or mode of connection of the flowers, is pointed out by Linnæus, as yielding the beſt ſpecific characters; though he, in theory at leaſt, excludes it from all authority in founding genera. In graſſes, nevertheleſs, every body recurs to this mark; though perhaps ſounder principles may hereafter be diſcovered for arranging even theſe.

The root almoſt invariably affords good and unchangeable ſpecific characters; but it is not always acceſſible, nor readily preſerved in a herbarium. Some graſſes moreover change their fibrous roots into bulbous ones, in conſequence of a fluctuation of ſoil or nutriment; and the bulbs of other plants very much alter their texture or appearance from ſimilar cauſes.

Great experience and ſagacity, with perhaps a peculiar talent, are requiſite to form a good judge of ſpecific characters. To convey a preciſe idea of them to others, requires a clearneſs of definition, and a command of language, granted to very few. Linnæus, with good reaſon, limits ſuch characters to a certain number of words, hardly exceeding twelve. However narrow theſe bounds may appear, we believe them to be in general, if not always, ſufficient; and every perſon will perceive that the conſequence of their tranſgreſſion is uſually feebleneſs, if not confuſion, of definition. It muſt always be remembered that ſpecific characters are *differences*, not *deſcriptions*. Hence a ſpecific character for a ſolitary ſpecies of any genus, is an abſurdity. It cannot contraſt ſuch a ſpecies with what are unknown, or perhaps do not exiſt. A ſhort deſcription may be very commodious or ſatisfactory to give an idea of the plant, eſpecially if the author miſtruſts his genus or its definition; but if the genus be good, the very characters which he will ſelect to delineate the habit, or prominent peculiarities, of the only known ſpecies, will, moſt likely, be common to any new ones that may ſubſequently be diſcovered.

Linnæus remarks, that the detection of genuine ſpecific diſtinctions is the ſummit of botanical ſkill. To which we may add, that thoſe have moſt excelled in this department who have caught the greateſt ſhare of the genius of this great man, whoſe definitions come as near to perfection as art can come to nature.

SPECIFIC, in *Philoſophy*, that which is proper and peculiar to any thing; or that characterizes it, and diſtinguiſhes it from every other thing. See PROPER, &c.

Thus, the attracting of iron is ſpecific to the load-ſtone, or is a ſpecific property of the load-ſtone. A juſt definition ſhould contain the ſpecific notion of the thing defined, or that which ſpecifies and diſtinguiſhes it from every thing elſe.

SPECIFIC, in *Medicine*, ſuch articles in the materia medica as have the ſpecial power of curing particular diſeaſes, in all perſons, and under all circumſtances, without demanding any attention to particular indications. In other words, a *ſpecific* is a certain antidote againſt a given diſeaſe. Notwithſtanding, however, the multitude of ſuch ſpecifics, which are every day announced by boaſting quacks, and teſtified to by all ranks of people, who are their dupes, it unfortunately happens that no ſuch remedies exiſt. As ſound ſcience has extended, all theſe vaunted ſpecifics have ſucceſſively been baniſhed from the confidence of men of ſenſe and information; and almoſt every remedy has ſome obvious action upon the animal ſyſtem, ſo that the principles of its operation in particular diſeaſes may be pointed out. Peruvian bark was formerly ſuppoſed to be a ſpecific for intermittents and agues; but it is now known to fail in many caſes, and not to be more efficacious than other medicines of a tonic power, ſuch as arſenic, and ſome combinations of bitters with aromatics, which are popularly uſed in agueiſh countries. The two medicines which approach the neareſt in their qualities to the character of *ſpecifics*, are *mercury*, as the antidote to the venereal poiſon, and *ſulphur*, to that of the itch. Indeed it is only in caſes of the actual exiſtence of a morbid poiſon, that any diſtinct antidote can poſſibly exiſt. But even with reſpect to theſe two medicines, it is well aſcertained that there are caſes of diſeaſe, ſo accurately reſembling lues venerea, as not to be diſtinguiſhable by the moſt acute and experienced eye, which nevertheleſs recover without the aid of mercury (ſee Mr. Abernethy's "Account of Diſeaſes which ſtrikingly reſemble the Venereal Diſeaſe"): and we know that the powers of ſulphur in curing the itch are conſiderably augmented by the addition of other ſubſtances, ſuch as hellebore, muriate of ammonia, the white oxyd of mercury, &c. All other inſtances of pretended ſpecifics are impoſitions.

SPECIFIC *Gravity*, in *Hydroſtatics*. See *Specific* GRAVITY.

SPECIFIC *Gravity of Living Men*. Mr. Robertſon, in order to determine the ſpecific gravity of men, prepared a ciſtern, 78 inches long, 30 inches wide, and 30 inches deep; and having procured 10 men for his purpoſe, the height of each was taken, and his weight; and afterwards they plunged ſucceſſively into the ciſtern. A ruler, graduated to inches and decimal parts of an inch, was fixed to one end of the ciſtern, and the height of the water noted before each man went in, and to what height it roſe when he immerſed himſelf under its ſurface.

The following table contains the ſeveral reſults of his experiments.

No. of Men.	Height.		Weight.	Height of Water before immerſed.	Height of Water when immerſed.	Water raiſed.	Solidity.	Weight of Water.
	Ft.	In.	Pounds.	In.	In.	In.		Pounds.
1	6	2	161	19.30	21.20	1.90	2.573	160.8
2	5	$10\frac{3}{8}$	147	19.25	21.16	1.91	2.586	161.6
3	5	$0\frac{1}{2}$	156	19.21	21.06	1.85	2.505	156.6
4	5	$6\frac{3}{4}$	140	19.17	21.21	2.04	2.763	172.6
5	5	$5\frac{7}{8}$	158	19.13	21.21	2.08	2.817	176.0
6	5	$5\frac{1}{2}$	158	19.09	21.26	2.17	2.939	183.7
7	5	$4\frac{3}{8}$	140	19.05	21.06	2.01	2.722	170.1
8	5	$3\frac{1}{8}$	132	19.01	20.86	1.85	2.505	156.6
9	5	$4\frac{1}{8}$	121	18.97	20.76	1.79	2.424	151.5
10	5	$3\frac{1}{4}$	146	18.93	20.66	1.73	2.343	146.4

One of the reaſons, Mr. Robertſon ſays, that induced him to make theſe experiments, was a deſire of knowing what quantity of fir or oak-timber would be ſufficient to keep a man afloat in river or ſea-water, thinking that moſt men were ſpecifically heavier than river or common freſh water; but the contrary appears from the trials above recited: for, excepting the firſt and laſt, every man was lighter than his equal bulk of freſh water, and much more ſo than his equal bulk of ſea-water: conſequently, if perſons who fall into water had preſence of mind enough to avoid the fright uſual on ſuch accidents, many might be preſerved from drowning; and a piece of wood, not larger than an oar, would buoy a man partly above water as long as he had ſpirits to keep his hold. Phil. Tranſ. vol. l. art. 5.

SPECIFIC *Gravity of Metals*. See the ſeveral metals.

SPECIFIC *Heat*. See HEAT.

SPECIFIC *Names*, in *Natural Hiſtory*, are thoſe epithets compoſed each of one or more terms, and placed after the generical name, in the denomination of any ſpecies of plant, animal, or mineral, expreſſing thoſe characters by which it differs from all the other ſpecies of that genus.

The more accurate of the modern naturaliſts have, in their ſeveral provinces, ſet about the reformation of the ſpecific names of things. They firſt obſerve, that many of the ſpecific names of the ancients no way anſwered the intent of their formation, but expreſſed the more trivial diſtinctions, or accidents, while they omitted the realities, and more eſſential grounds of diſtinction. On this foundation the critical writers of our times diſtinguiſh the old ſpecific names into the genuine or true, and the ſpurious or falſe ones.

The genuine names are thoſe which expreſs thoſe characters,

ters, by means of which the thing becomes a different ſpecies; theſe are invariable, and by theſe names the thing is, in ſome ſort, deſcribed. The falſe ones are thoſe ſpecific names which do not, and cannot diſtinguiſh the ſpecies called by them from the others of the ſame genus, which may as well belong to ſome other ſpecies as to that, and which therefore are of no uſe to the ſtudent. The true formation of theſe names is on the real characters of the body to be named; but inſtead of this, theſe falſe ones are often formed from accidental or variable diſtinctions.

Specific *Waters*. See Water.

SPECIFICATION, a term expreſſing the engineer's ſtatement of the particulars of width, depth, ſlopes, &c. which a certain length of canal is to have, when the excavation is to be made by contract.

Specification is likewiſe a term uſed in obtaining patents. See Patent.

SPECILLUM, a probe, one of the moſt common inſtruments of ſurgery. See *Surgical Plates*.

SPECIOUS Arithmetic. See Arithmetic.

SPECKHAVEN, in *Geography*, a harbour on the W. coaſt of Weſt Greenland. N. lat. 64°. W. long. 49° 40′.

SPECKLED Beans, in *Agriculture*, a term applied to ſome ſorts of the kidney-bean, which are occaſionally cultivated in the field, in ſome diſtricts. The principal varieties which are grown and cultivated in this way in ſome parts of the county of Kent, are the black ſpeckled and the red ſpeckled; but many others may be employed for the ſame purpoſe.

The tillage preparation of the land for field-crops of this ſort is the ſame as that which is made uſe of for the growth of the common pea and bean; and the manure, which is commonly ploughed in before the ſeed is put into the ground, is of the more rotten dung kind. See Peas and Beans.

The time of planting crops of this nature in the field is in the early part of the ſpring, as from about the eighth to the twentieth of May, as when it is done earlier, the crops are in danger of being injured, or wholly deſtroyed, by the occurrence of a froſty morning, which is then liable to take place.

In ſetting, the ſeed-beans are dropped by the hand into holes, or ſmall furrows or drills made for the purpoſe in the land, in the quantity of from five to ten gallons to the acre, in proportion to the ſize of the ſort which is employed; the ſmaller the ſort of bean, the leſs the quantity which is neceſſary.

The crops are repeatedly hoed while growing, ſo as to be kept perfectly clean and free from weeds of all kinds; and in their more early growth the fine mould is a little drawn up to the rows, in order to promote the advancing of the young plants.

The harveſting of the crops is by pulling up the plants by the roots, as the beans become ripe, during the beginning of the autumnal ſeaſon. The more early ſorts are commonly ready and fit to be pulled about the end of Auguſt; but the late ones are often not ripe and ready for pulling until the month of October. Thoſe which ripen ſo late in the ſeaſon, and are in danger of being injured by wet weather, are frequently tied up in ſmall bunches, and hung upon poles to finiſh their ripening, and, when thoroughly dry, are threſhed out and ſent to market, as they ſeldom keep well.

Theſe ſorts of bean-crops are much cultivated and attended to about the town of Sandwich, and in the Iſle of Thanet, in the ſame county, as well, perhaps, as in ſome other ſouthern parts of the iſland, for the purpoſe of ſupplying the London ſeedſmen with theſe kinds of beans. See Phaseolus.

This is a profitable ſort of culture in ſome caſes and ſeaſons, but liable to much uncertainty.

SPECTABILES, among the Romans, a title of honour given to the ſecond rank, or degree of nobility, under the Roman emperors, being unknown in the time of the republic. There were two other degrees; the firſt had the title of *illuſtres*, and the third that of *clariſſimi*.

SPECTACLE, Spectaculum, *Show*; ſome extraordinary object, which draws the view and attention; and is not beheld without ſome emotion or paſſion of the mind.

The term is chiefly uſed, by the ancients, for theatrical and amphitheatrical performances; for comedies, combats of gladiators, and of beaſts; and even for ſolemn proceſſions, as thoſe of the Circus, &c.

The people of Rome were extremely fond of ſpectacles; and the Roman hiſtorians obſerve, that there was no ſurer way of gaining their affections, and making parties to introduce tyranny and oppreſſion, than by the uſe of ſpectacles.

SPECTACLES, an optic machine, conſiſting of two lenſes ſet in a frame, and applied on the noſe, to aſſiſt in defects of the organ of ſight.

It is well known, that parallel rays, or ſuch rays as proceed from a very diſtant luminous point, will be collected, by the refractions of all the humours through which they muſt paſs in the eye, to a focus on the retina, which is the true place of the image. But at the ſame time it is evident, that if that be the focal diſtance for parallel rays, it cannot be the focal diſtance for diverging rays; or, in other words, when the objects are ſituated at a few feet diſtance from the eye, their true images muſt be formed farther back; conſequently their images upon the retina muſt be imperfect, unleſs the retina be ſituated farther back by an elongation of the axis of the eye, or the focal diſtance be ſhortened by the alteration of ſome other part. But ſince we may perceive either diſtant or near objects diſtinctly, it is evident that ſome ſuch alteration does actually and neceſſarily take place. This is called the adjuſtment, or accommodation of the eye for diſtinct viſion; but the difficulty is to determine how this adjuſtment is effected.

By ſome perſons it has been attributed to a change in the length of the eye, and by others to a change of curvature in the cornea; but ſome very recent experiments render thoſe alterations unlikely, at leaſt to the full amount of what may be required. Other ingenious perſons have attributed the alteration to a change either of the ſhape of the cryſtalline lens, or of its ſituation, or of both; and this opinion ſeems upon the whole to be nearer the truth.

That the eye cannot ſee both near and remote objects diſtinctly at the ſame time, may be eaſily proved. Let a tree, a houſe, or ſome other object, be upwards of fifty feet from you; ſhut one eye, and whilſt you are looking with a ſingle eye at the tree, &c. hold a pin, a pencil, or ſome other object, in the ſame direction, at about a foot diſtance from the eye; and it will be found, that whilſt you ſee the pin diſtinctly, the tree will appear indiſtinct; but if you adjuſt your eye ſo as to ſee the tree diſtinctly, then the pin will appear indiſtinct.

The eyes of ſome perſons are more capable of adjuſtment than thoſe of others. In old perſons the humours grow thicker, and the parts leſs pliable; hence their eyes are leſs capable of adjuſtment than thoſe of young perſons.

The eyes of ſome perſons can be adjuſted for diſtant objects better than for near objects, and *vice verſâ*. When the eye is defective, and by its ſize or other conformation, parallel rays form their foci before they arrive at the retina, then the perſon can ſee very near objects only. Such perſons are ſaid to be near-ſighted, or they are called *myopes*. When the eye is flatter than ordinary, then the foci of rays from pretty near objects are formed beyond the retina. Perſons with ſuch eyes are called *preſbytæ;* they can adjuſt their eyes for objects beyond a certain diſtance only. The latter is generally the caſe with old perſons; but the eyes of old perſons ſometimes are incapable of adjuſtment both for very near and for very diſtant objects. This comes from a rigidity or want of pliability in the parts. Thoſe defects are frequently brought on or increaſed by habit, as by the conſtant cuſtom of viewing objects either from too near or from too great a diſtance; as alſo by the uſe of improper glaſſes.

Thoſe imperfections may in a great meaſure be remedied by the uſe of proper glaſſes or ſpectacles; for ſince, in near-ſighted perſons, the rays of light converge to a focus too ſoon, *viz.* before they come to the retina, concave lenſes, which diminiſh the convergency, muſt remove the imperfection. And for thoſe who can ſee diſtant objects only with tolerable diſtinctneſs, *viz.* in whoſe eyes the rays do not converge ſoon enough, convex lenſes, which increaſe the convergency, muſt remove the imperfection.

When the defect comes from rigidity, as in ſome old perſons, then thoſe perſons require concave glaſſes for viewing diſtant objects, and convex glaſſes for viewing near objects; for their eyes want both adjuſtments.

The capability of adjuſtment is greater or leſs in different eyes, and it is frequently different in the two eyes of the very ſame perſon; but in all eyes there is a limit, within which viſion is not diſtinct. This is called the *limit of diſtinct viſion;* and with ſome perſons it is as ſhort as one inch, whilſt in others it exceeds twenty inches; but in common it will be found to lie between ſix and ten inches.

In Spain, and at Venice eſpecially, ſpectacles have been uſed with a different view from either of thoſe above ſtated; all the people of note and faſhion there have them continually on their noſes: a folly, that has its ſource in the natural pride of thoſe people, who value themſelves on a profound wiſdom; and affect to ſtare very near at every thing; as if their eyes were weakened, and worn out with exceſs of attention. Vign. de Mary.

F. Cherubin, a Capuchin, deſcribes a kind of ſpectacle teleſcopes, for the viewing of remote objects with both eyes; hence called *binoculi;* though F. Rheita had mentioned the ſame before him, in his "Oculus Enoch et Eliæ." See Binocle.

The ſame author invented a kind of ſpectacles, with three or four glaſſes, which performed extraordinarily.

Spectacles were certainly unknown to the ancients. Franciſco Redi, in a very learned treatiſe on ſpectacles, will have them to have been invented in the 13th century, between the years 1280 and 1311, (probably about the year 1299 or 1300,) and adds, that Alexander de Spina, a monk of the order of Predicants of St. Catharine, at Piſa, firſt communicated the ſecret, which was of his own invention; upon learning that another perſon had it as well as himſelf. This hiſtory is written in the chronicles of that convent.

The ſame author tells us, that in an old manuſcript ſtill preſerved in his library, compoſed in 1299, ſpectacles are mentioned as a thing invented about that time: and that a famous Jacobin, one Jourdon de Rivalto, in a treatiſe compoſed in 1305, ſays expreſsly, that it was not yet twenty years ſince the invention of ſpectacles. He likewiſe quotes Bernard Gordon in his "Lilium Medicinæ," written the ſame year, where he ſpeaks of a collyrium, good to enable an old man to read without ſpectacles.

Muſchenbroeck, Introd. vol. ii. p. 786, obſerves, that it is inſcribed on the tomb of Salvinus Armatus, a nobleman of Florence, who died in 1317, that he was the inventor of ſpectacles.

Du-Cange, however, carries the invention of ſpectacles farther back; aſſuring us, that there is a Greek poem in manuſcript in the late French king's library, which ſhews, that ſpectacles were in uſe in the year 1150; nevertheleſs, the Dictionary of the Academy della Cruſca, under the word *occhiale*, inclines to Redi's ſide; and quotes a paſſage from Jourdon's Sermons, which ſays that ſpectacles had not been twenty years in uſe: and Salvati has obſerved, that thoſe ſermons were compoſed between the years 1330 and 1336.

It is probable that the firſt hint of the conſtruction and uſe of ſpectacles was derived from the writings either of Alhazen, who lived in the 12th century, or of our own countryman Roger Bacon, who was born in 1214, and died in 1292 or 1294. The following remarkable paſſage occurs in Bacon's "Opus Majus," by Jebb, p. 352. "Si vero homo aſpiciat literas et alias res minutas per medium cryſtalli vel vitri, vel alterius perſpicui ſuppoſiti literis, et ſit portio minor ſpheræ, cujus convexitas ſit verſus oculum et oculus ſit in aere, longe melius videbit literas, et apparebunt ei majores.—Et ideo hoc inſtrumentum eſt utile ſenibus et habentibus oculos debiles: nam literam quantumcunque parvam poſſunt videre in ſufficienti magnitudine." Hence, and from other paſſages in his writings much to the ſame purpoſe, Molyneux, Plott, and others, have attributed to him the invention of reading-glaſſes.

Dr. Smith, indeed, obſerving that there are ſome miſtakes in his reaſoning on this ſubject, has diſputed his claim. See Molyneux's Dioptrics, p. 256. Smith's Optics, Rem. 86—89.

The eſſential and extenſive uſe of ſpectacles, which affords comfort to ſo great a number of individuals, who would otherwiſe be a burden to themſelves and to ſociety, is an inſtance of the great uſefulneſs of the ſcience of optics.

No pains have been ſpared to render ſpectacles as perfect as poſſible, and a variety of contrivances have been from time to time offered to the public. Spectacles have been made with two lenſes for each eye; alſo the lenſes have been made plano-convex, or plano-concave, or of other ſhapes; but, upon the whole, ſingle lenſes, either double concave, or double convex, of clear glaſs, well poliſhed and regularly formed, are the beſt.

When the eyes of perſons firſt begin to be affected by age, the opticians furniſh them with ſpectacle lenſes, of about forty inches focus, which glaſſes are therefore called number 1ſt, or glaſſes of the firſt ſight; *viz.* for the ſight when it firſt begins to be impaired by age. But there is conſiderable difference between the focal diſtances of ſpectacles. N° 1, made by different opticians. When the focal length is about ſixteen inches, the lenſes are called N° 2. About twelve inches are the focal length of N° 3. Ten inches are what they call N° 4. Nine inches are thoſe of N° 5. Eight inches give the focal length of N° 6. Seven inches are the focal length of N° 7. Six inches are the focal length of N° 8. And ſometimes they make ſpectacles of a focus ſhorter ſtill. Concave ſpectacles are alſo named by ſimilar numbers.

In chooſing ſpectacles, actual trial is the beſt guide; but care muſt be had to uſe ſpectacles that do not magnify more than is juſt ſufficient either for reading, or for other neceſſary purpoſes.

When a variety of ſpectacles cannot actually be tried, the defect of the ſight may be expreſſed by mentioning the diſtance from which the perſon can read, or other peculiarities, from which the neceſſary glaſſes may be determined pretty nearly. For an account of the inſtrument for meaſuring the exact limits of diſtinct viſion, invented by Dr. Porterfield, and improved by Dr. T. Young, ſee Optometer.

Huygens conceived, that the glaſſes of ſpectacles, inſtead of being equally curved on both ſides, ſhould have the curvatures of their oppoſite ſurfaces in the proportion of 6 to 1, and the moſt convex ſide turned towards the object, becauſe he had demonſtrated that ſuch a form was beſt ſuited to the object-glaſſes of teleſcopes, as having leſs aberration than any other form of lens.

Dr. Wollaſton obſerves, that although it may be true that ſuch a form of glaſs was beſt calculated for the object-glaſs of a teleſcope, previouſly to the celebrated diſcovery of the achromatic object-glaſs by the late Mr. Dollond, yet whatever advantages might at any time be expected from the teleſcopic object-glaſs ſo ſhaped, theſe were not to be obtained by a ſimilar conſtruction in ſpectacles, as may eaſily be ſeen by conſidering the different uſes of the reſpective inſtruments.

In a teleſcope, in the firſt place, our view is neceſſarily confined to a very ſmall diſtance on each ſide of the axis; and, ſecondly, every part of the object-glaſs contributes to the diſtinctneſs of any object viewed.

It is under theſe circumſtances alone, that the proportion of the curvatures above-mentioned might be proper for a ſingle object-glaſs, as being capable of collecting into the ſame focus the rays that fall on every part of it parallel to the axis. But by ſpectacles, on the contrary, objects are to be viewed, if poſſible, in every direction in which they might be ſeen by the naked eye, which is often removed from the centres of the glaſſes; conſequently, a conſtruction that is calculated to repreſent correctly central objects alone cannot be the moſt advantageous.

In ſpectacles alſo the portion of the glaſs employed at once is ſcarcely larger than the pupil of the eye; ſo that any endeavour to procure the concurrence of all parts of a glaſs in any one effect is evidently ſuperfluous, and may alſo be ſhewn to be prejudicial.

Mr. B. Martin, ſo well known by his numerous writings upon philoſophical and mathematical ſubjects, made ſpectacles ſixty years ago, which he called viſual glaſſes, and in which the two glaſſes were not ſituated in the ſame plane, or with their axes parallel to each other, but were placed inclined to each other, in the ſame angle as the pencils of rays muſt proceed from the objects which are viewed, and come to the two eyes. Reſpecting the common glaſſes, this writer obſerves, in his treatiſe upon ſpectacles, that he conſidered the two glaſſes of a common pair of ſpectacles, when placed both in the ſame plane, and with their axes parallel to each other, as being moſt adapted to view objects at a very great diſtance, where we can ſee no objects with them at all; for, when we uſe ſpectacles, the axes of both eyes are always turned to the object which we view, and meet in a point in it, as in reading, writing, working with a needle, &c.; conſequently the axes of the eyes, and of the glaſſes, are ſo far from coinciding, that they make a conſiderable angle with each other, by which means the eye is deprived of the principal pencil of rays, *viz.* thoſe rays which belong to the axes of each of the glaſſes, and which will make the moſt perfect part of the image on the retina of the eye, and which rays alone can produce perfect viſion. Thoſe rays alone can enter the eye from the object we look at, which come on one ſide of the glaſs, or obliquely to its axis, and are therefore regularly refracted to the eye, ſo as to make the viſion in proportion imperfect.

As the action of light upon the eye tends gradually to weaken it, no more of ſuch an active principle ſhould be admitted into ſo delicate and fine a ſtructure as that of the eye, than what is quite neceſſary to illuminate the object, and make it ſufficiently viſible. But the common ſize of ſpectacle-glaſſes pours in upon the eye-balls three times as much as is neceſſary for this purpoſe, and, therefore, is very prejudicial to the eyes in that reſpect, for in time it makes them weak and watery. Further, it is well known that only a particular quantity of light is proper for perfect and diſtinct viſion; and that a greater or leſs degree of it always impairs and confuſes the image, and conſequently the viſion of the object. For this purpoſe, in microſcopes, teleſcopes, and other optical inſtruments, proviſions are made to regulate the quantity of light by proper apertures and diaphragms; but in ſpectacles, where the quantity of light ſhould be in the higheſt degree regulated and adjuſted, no proviſion at all has been made, but the tender ſyſtem of the eye has been left defenceleſs from the ſuperfluous and injurious particles of light.

In common ſpectacles, only thoſe rays of light which fall near the axis of the glaſſes, can be regularly refracted to the eye, and conſequently only ſuch can make the image, or viſion of the object, in any degree perfect: and, therefore, conſidering the unreaſonable area or diameter of the glaſſes of common ſpectacles, there muſt neceſſarily be a great quantity of light that will not only annoy the image by ſuffuſion, but greatly affect the eye, and render the image imperfect by an irregular refraction from all the extreme parts of the glaſs.

The lenſes of Mr. Martin's ſpectacles were ſo fixed in their frame, that the axes of the two glaſſes were inclined to each other, and met in one point, ſituated at the ſame diſtance from the glaſſes as the focus of each glaſs reſpectively; or, in other words, the foci of the two glaſſes were brought into one common point: whereas in the common ſpectacles, the axes of the two glaſſes being parallel, the two foci are at the ſame diſtance apart as the centres of the glaſſes are. Mr. Martin alſo recommended opticians to make the glaſſes ſmaller; an alteration which was attended with conſiderable advantages: for, before his time, the lenſes were frequently made an inch and a half in diameter.

Dr. Franklin uſed a pair of double or biſected ſpectacles, which he thus deſcribes in a letter to one of his friends. "The ſame convexity of glaſs, through which a man ſees cleareſt and beſt at the diſtance proper for reading, is not the beſt for greater diſtances. I, therefore, had formerly two pairs of ſpectacles, which ſhifted occaſionally; as in travelling I ſometimes read, and often want to regard the proſpects. Finding this change troubleſome, and not always ſufficiently ready, I had the glaſſes cut out, and half of each kind aſſociated in the ſame circle; the leaſt convex, for viewing diſtant objects, in the upper half of the circle; and the moſt convex, proper for reading, in the lower half of the frame. By this means, as I wear my ſpectacles conſtantly, I have only to move my eyes up or down, as I want to ſee diſtinctly far or near; the proper glaſſes being always ready. Although I cannot diſtinguiſh a letter, even of large print, by the naked eye, with the aſſiſtance of this invention, my eyes are as uſeful to me as ever they were;

and if all the other defects and infirmities of old age could be as eaſily and cheaply remedied, it would be worth while to live a good deal longer."

Mr. John Richardſon, an optician of London, obtained a patent in 1797 for an improvement in ſpectacles, which conſiſts in applying extra glaſſes before the common ſingle lenſes, and fitted with joints, ſo that the extra glaſſes can at pleaſure be turned up out of the way, either on one ſide, or upwards. The advantage of this plan is ſtated to be, that it precludes the neceſſity of two pairs of ſpectacles for different views, but that any two different powers of ſight may be inſtantly obtained: for inſtance, the ſpectacles may be fitted with ſuch lenſes as are moſt proper to enable the wearer to ſee a proſpect in walking or riding; but by turning down the extra lenſes, the ſpectacles will magnify in a greater degree, and be proper for reading or writing; and by the ſame means, coloured glaſſes may be applied, to be occaſionally turned down over the lenſes of the ſpectacles, to walk in the ſun-ſhine.

Mr. John Iſaac Hawkins ſome years ago introduced a new kind of ſpectacles, provided with extra arms or joints, which paſs upwards over the temples, in addition to the uſual jointed arms which hold the ſpectacles, by paſſing horizontally round the head. By theſe additional arms the ſpectacles are borne altogether from the head, without reſting upon the noſe, which occaſions an unpleaſant ſenſation to thoſe who firſt begin to uſe ſpectacles, although it wears off in a few days; but the advantage of Mr. Hawkins's plan is, that the glaſſes, without occaſioning any preſſure on the temples, can be placed at any diſtance from the eye, and inclined in any direction, as is found moſt convenient for the view.

Dr. Hyde Wollaſton's periſcopic ſpectacles are now much in uſe, and are ſo called from the facility which they afford the wearer of looking round at various objects. This invention, for which he obtained a patent in 1804, is intended to obviate that defect of the common ſpectacle-glaſſes, which we have before mentioned, *viz.* that no objects appear diſtinct through them, except ſuch as are ſeen through the centre of the glaſſes, or nearly ſo, and that the viſion is indiſtinct, in proportion as the part of the glaſs through which the rays paſs is farther from the centre: this is moſt particularly obſervable in glaſſes of ſhort focal diſtance, and conſiderable magnifying power. It is on this account that opticians have lately made and recommended ſpectacle-glaſſes of leſs diameter than thoſe formerly in uſe, thinking that the extreme parts of the field of viſion, which from indiſtinctneſs were of little uſe, might be ſpared without much inconvenience. But this alteration in the ſize of the glaſſes can ſcarcely be called an improvement, ſince for one defect it only ſubſtituted another ſcarcely leſs objectionable.

Dr. Wollaſton, having conſidered that the portion of any glaſs employed in any one poſition of the eye is but ſmall, perceived, that by making the ſubſtance of a glaſs curved, in the manner of a hollow globe, each portion of it might be ſituated nearly at right angles to the direction of the ſight, and would thereby render lateral objects diſtinct, without impairing the diſtinctneſs at the centre.

To illuſtrate this; ſuppoſing the eye to be placed in the centre of any hollow globe of glaſs, it is plain, that objects would then be ſeen perpendicularly through its ſurface in every direction: conſequently, the more nearly any ſpectacle-glaſs can be made to ſurround the eye, in the manner of a globular ſurface, the more nearly will every part of it be at right angles to the line of ſight, the more uniform will be the power of its different parts, and the more completely will the indiſtinctneſs of lateral objects be avoided. It is evident, that no other rays than thoſe which paſs through the centre of a lens can be at right angles to both ſurfaces; but it is equally clear, that when any ſmall oblique pencil of rays makes equal angles with the two ſurfaces of a thin lens, its inclination to each ſurface will be ſo ſmall, that its focal length will not ſenſibly differ from that of a central pencil. Upon this principle Dr. Wollaſton's ſpectacle-glaſſes are made, of a form not heretofore uſed for that purpoſe; the outer ſurface of each glaſs, or that which is fartheſt from the eye, being ſpherically convex, and the inner ſurface of the ſame glaſs, or that which is neareſt the eye, ſpherically concave. A glaſs of this ſort, adapted for a ſhort-ſighted perſon, will have the interior and concave ſurface of each glaſs more curved than the exterior and convex ſurface of the ſame glaſs, by which the rays of light paſſing through the ſame are diverged, and the degree of curvature of the interior and concave ſurface is to be increaſed in proportion as the perſon who is to uſe the glaſſes is more ſhort-ſighted. On the contrary, for long-ſighted perſons, the form of each glaſs muſt be ſuch as to have the exterior and convex ſurface thereof more curved than the interior and concave ſurface of the ſame glaſs, by which means the rays of light paſſing through the ſame are converged; and the degree of curvature of the exterior and convex ſurface of the glaſs is to be increaſed in proportion as the perſon to uſe the glaſs is more long-ſighted.

With a view of obtaining the ſame effects as Dr. Wollaſton's periſcopic ſpectacles, a new ſpecies of glaſſes have been lately introduced at Paris, made by Chamblant, optician, Rue Baſſe, Porte St. Denis; they are called *conſerves:* theſe glaſſes are ground to cylindrical ſurfaces, inſtead of the ſpherical ſurfaces which have hitherto been employed for ſpectacles and lenſes of all kinds: the oppoſite ſurfaces of each glaſs are ſegments of two different cylinders, inclined to each other at right angles; that is, the axes of the two cylinders are ſituated in parallel planes, but in direction they lie at right angles to each other, and in conſequence, the direction in which one ſurface of ſuch a glaſs is curved, is at right angles to the direction in which the other ſide is curved. On making trial of a pair of theſe glaſſes, we found them very perfect in the field of view, preſenting a very diſtinct viſion of objects viewed through the outer parts of the glaſs, as well as thoſe viewed through its central parts: and the magnifying power of the whole field as nearly equal as the eye could judge.

The inventor has obtained a patent in France for this invention, and makes ſpectacles of all degrees of magnifying power. He propoſes to apply ſimilar lenſes to teleſcopes, microſcopes, and other optical inſtruments, but we have not had an opportunity of examining any of them.

Spectacles are made in great varieties of forms, and ornamented according to faſhion, or to the fancy of the wearer. The frames are made of all kinds of materials, ſuch as gold, ſilver, ſteel, pearl, tortoiſe-ſhell, ivory, bone, and wood. The lenſes are uſually made of glaſs, but the better ſorts are made of natural cryſtal, and are known by the name of pebble-ſpectacles, but in reality moſt of the ſpectacles ſold under that name are made of a hard ſort of glaſs.

It is obſerved by Mr. Ware (Phil. Tranſ. for 1813, part I.) that ſhort-ſightedneſs uſually comes on between the ages of ten and eighteen. This defect of ſight, as ſoon as it is accidentally diſcovered, is little regarded by perſons in the inferior ſtations of ſociety, and no means are uſed for correcting it; hence by increaſed exertions that are made for diſtinguiſhing diſtant objects, the imperfection is not unfrequently

quently overcome. But when perſons in the higher ranks of life diſcover that their diſcernment of diſtant objects is leſs quick or leſs correct than that of others, however ſlight the difference may be, ſuch perſons, influenced perhaps by faſhion more than by neceſſity, recur immediately to the uſe of a concave glaſs; and thus their eyes become ſo fixed in the ſtate requiring its aſſiſtance, that the recovery of diſtant viſion is rendered afterwards extremely difficult, if not quite impoſſible. The number of perſons who actually need this aſſiſtance, is comparatively very inconſiderable; and therefore it ſhould more generally be avoided. The misfortune reſulting from the uſe of concave glaſſes is this, that the near-ſightedneſs is not only fixed by it, but from a habit of inquiry with regard to the extreme perfection of viſion, frequent changes are made for glaſſes that are more and more concave, until at length the near-ſightedneſs becomes ſo conſiderable, as to be rendered ſeriouſly inconvenient and afflicting. It ought to be remembered, that, for common purpoſes, every near-ſighted eye can ſee with nearly equal accuracy through two glaſſes, one of which is one number deeper than the other; and though the ſight be in a ſlight degree more aſſiſted by the deepeſt of theſe than by the other, yet on its being firſt uſed, the deepeſt number always occaſions an uneaſy ſenſation, as if the eye were ſtrained. If, therefore, the glaſs that is moſt concave be at firſt employed, the eye, in a little time, will be accommodated to it, and then a glaſs one number deeper may be uſed with ſimilar advantage to the ſight; and if the wiſh for enjoying the moſt perfect viſion be indulged, this glaſs may ſoon be changed for one that is a number ſtill deeper, and ſo in ſucceſſion, until at length it will be difficult to obtain a glaſs ſufficiently concave to afford the aſſiſtance which the eye requires. Mr. Ware obſerves, that moſt of the near-ſighted perſons whom he has known, have had the right eye more near-ſighted than the left; and he thinks it not improbable, that this difference between the two eyes has been occaſioned by the habit of uſing a ſingle concave hand-glaſs; which, being commonly applied to the right eye, contributes to render this eye more near-ſighted than the other. In ſome caſes children have manifeſted near-ſightedneſs almoſt as ſoon as they begin to take notice of ſurrounding objects; but this, which is occaſioned by ſome degree of opacity in the tranſparent parts of the eye, is very different from that ſtate of the eye to which the term myopic, or near-ſightedneſs, is uſually applied; and by which is ſimply meant too great a convexity either in the cornea or in the cryſtalline, in proportion to the diſtance of theſe parts from the retina. So far from diſcouraging the uſe of ſpectacles in ſuch caſes, it is neceſſary to recur to them, as without them children could not proſecute their learning with eaſe or convenience. Extreme near-ſightedneſs is ſometimes occaſioned by an evident change in the ſpherical figure of the cornea, and its aſſumption of a conical ſhape. This morbid ſtate of the cornea admits of no amendment by any glaſs. The cornea, in moſt caſes of this kind, is preternaturally thin; and it is not unfrequently accompanied with ſymptoms of general debility, under which laſt circumſtance, chalybeate medicines, and bracing applications to the eye, have afforded conſiderable benefit. Near-ſightedneſs, our author ſays, is ſeldom alike in the two eyes, and he has obſerved a few caſes, in which one eye of the ſame perſon has had a near, and the other a diſtant ſight. Dr. Porterfield has ſuggeſted, that the pupils of near-ſighted perſons are more dilated than thoſe of others; but this does not accord with Mr. Ware's obſervations in ſuch caſes. This ingenious writer, whoſe remarks on all circumſtances relating to the eye merit peculiar attention, obſerves, that near-ſightedneſs has no dependence on the greater or ſmaller degree of convexity poſſeſſed by the cornea, when this circumſtance is conſidered alone; ſince the length of the axis of the eye from the cornea to the retina, and the greater or ſmaller degree of convexity in the cryſtalline humour, muſt be alſo regarded before the diſtance of accurate viſion can be determined. It is alſo no leſs evident, that near-ſightedneſs is not neceſſarily occaſioned by a morbid protruſion of the whole eye; ſince ſome perſons are born with eyes of this deſcription, and others acquire the peculiarity, when further advanced in life, in conſequence of a morbid accumulation of *adeps* at the bottom of the orbit, without either of them being more near-ſighted than thoſe who are free from this imperfection. It is a fact often noticed, that old perſons, who have been long accuſtomed to uſe convex glaſſes of conſiderable power, have recovered their former ſight, even at the advanced age of 80 or 90 years, and have then had no further need of them. This amendment is aſcribed by Dr. Porterfield to a decay of *adeps* at the bottom of the orbit; but Mr. Ware attributes this remarkable revolution in the ſight of old perſons to an abſorption of part of the vitreous humours; in conſequence of which, the ſides of the ſclerotica are preſſed inward, and the axis of the eye, by this lateral preſſure, is proportionably lengthened. This kind of alteration is alſo ſufficient to explain the reaſon, why ſuch aged perſons retain the power of diſtinguiſhing objects at a diſtance, at the ſame time that they recover the faculty of ſeeing thoſe that are near; ſince the lengthened axis of the eye leaves the power by which it is adjuſted to ſee at different diſtances, preciſely in the ſame ſtate in which it was before the lengthening of the axis took place. The faculty, ſays Dr. T. Young, of ſeeing at different diſtances, is produced by a power in the cryſtalline humours to become more or leſs convex, according as the object is more or leſs diſtant from the eye.

Although old perſons loſe the power of diſtinguiſhing correctly near objects, and require for this purpoſe the aid of convex glaſſes, they uſually retain the ſight of thoſe that are diſtant as well as when they were young. Inſtances, however, occur of perſons advanced in life, who require the aid of convex glaſſes to enable them to ſee near, as well as diſtant objects. From the caſe of perſons who have had the cryſtalline humour removed, Mr. Ware infers, that this humour is indiſpenſably neceſſary to enable the eye to ſee at different diſtances. Such perſons alſo have leſs power to aſcertain the diſtance of an object when they look through a convex glaſs than when they view it without this aſſiſtance; and accordingly ſuch perſons ſeldom make uſe of glaſſes when they are walking; and the inconvenience of glaſſes is particularly experienced when they deſcend a flight of ſteps, or paſs over uneven ground. Our author obſerves, that near-ſighted perſons do not appear to poſſeſs the ſame extent of viſion that is enjoyed by thoſe who have a diſtant ſight, and he verifies the obſervation by a ſtatement of his own caſe, whoſe range of diſtinct viſion did not extend further than an inch and a quarter in either eye, and within theſe diſtances he always held a book when he read. He recommends the following rule for determining the concavity of a glaſs that is beſt adapted for near-ſighted perſons, to thoſe who are unable, from diſtance or any other cauſe, to ſuit themſelves at the ſhop of an expert optician. The rule is this: multiply the diſtance at which the perſon reads with eaſe, (which in our author's caſe, with his left or beſt eye, was five inches,) by that at which he wiſhes to read, which may be ſtated at 12 inches; divide the product, 60, by 7, the difference between the two, and it leaves nearly 9 inches for the focus of the concave glaſs that ſhall produce the deſired effect. This glaſs anſwers to that ſold under the name of N° 6; and this is a double concave glaſs, ground on a tool of 8 inches radius on one ſide, and 11 inches on the other, the mean between which is very nearly 9 inches. From the whole ſtatement of our author, he infers, 1. That near-ſightedneſs is rarely obſerved in infants, or even in children under ten years of age. It affects the higher claſſes of ſociety more than the lower; and few inſtances occur, if any, in which, if the uſe of concave glaſſes has been adopted, increaſing years have either removed or leſſened this imperfection. 2. Although the uſual effect of time on perfect eyes is that of inducing a neceſſity to make uſe of concave glaſſes, in order to ſee near objects diſtinctly, yet ſometimes, even after the age of 50, and after convex glaſſes have been uſed many years for this purpoſe, the eyes have not only ceaſed to derive benefit from them, when looking at near objects, but they have required concave glaſſes to enable them to diſtinguiſh, with preciſion, objects at a diſtance. 3. Although the cauſe of this change be not always known, yet ſometimes it has been induced by the uſe of evacuating remedies, particularly of leeches applied to the temples; and ſometimes by looking through a microſcope, for a conſiderable length of time, on ſeveral ſucceſſive days. 4. Inſtances are not uncommon, in which perſons far advanced in life, (*viz.* between 80 and 90,) whoſe eyes have been accuſtomed for a long time to the uſe of deeply convex glaſſes, when they have read or written, have ceaſed to derive benefit from theſe glaſſes, and they have become able, without any aſſiſtance, to ſee both near and diſtant objects almoſt as well as when they were young. This change is probably owing to an abſorption of part of the vitreous humour, by which the axis is lengthened; and thus its length, from the cornea to the retina, is brought into the ſame proportion to the flattened ſtate of the cornea, or cryſtalline, or both, which it had to theſe parts before the alteration took place.

SPECTATOR, a perſon preſent at a ſpectacle.

Among the Romans, ſpectators, ſpectatores, more particularly denoted a kind of gladiators, who had received their diſcharge; and were frequently hired to be preſent as ſpectators at the combats of gladiators, &c. with which the people were entertained. See Rudiarius.

SPECTER, in *Conchology*, a name given by the French naturaliſts to a ſpecies of voluta, on which there are ſeveral reddiſh broad bands, compoſed of looſe and irregular figures; the ground colour is a fine white. They are called by Latin writers *concha ſpectrorum*.

SPECTRORUM Candela, in *Natural Hiſtory*, a name by which ſome have called the belemnites.

SPECTRUM, Ocular, in *Optics*, a name given by Dr. Darwin (Phil. Tranſ. for 1786) to an image, reſembling in form the object to which the obſerver was attending, and which continues for ſome time to be viſible, on cloſing his eyes or covering them, after having been long and attentively looking at a bright object, ſuch, *e. g.* as the ſetting ſun. Theſe ocular ſpectra, he ſays, are of four kinds; *viz.* 1. Such as are owing to a leſs ſenſibility of a defined part of the retina, or "ſpectra from defect of ſenſibility." 2. Such as are owing to a greater ſenſibility of a defined part of the retina, or "ſpectra from exceſs of ſenſibility." 3. Such as reſemble their object in colour as well as in form, which may be termed "direct ocular ſpectra." 4. Such as are of a colour contrary to that of their object, which may be termed "reverſe ocular ſpectra." The author, from experiments which he has detailed, concludes, that the retina is in an active, not in a paſſive ſtate, during the exiſtence of theſe ocular ſpectra; and hence he infers, that all viſion is owing to the activity of this organ. In the firſt caſe, the retina is not ſo eaſily excited into action by leſs irritation, after having been lately ſubjected to greater. In the ſecond, the retina is more eaſily excited into action by greater irritation, after having been lately ſubjected to leſs. In the third, a quantity of ſtimulus greater than natural excites the retina into ſpaſmodic action, which ceaſes in a few ſeconds: and a quantity of ſtimulus ſomewhat greater than the laſt excites the retina into ſpaſmodic action, which ceaſes and recurs alternately. In the fourth caſe, the retina, after having been excited into action by a ſtimulus ſomewhat greater than the laſt mentioned, falls into oppoſite ſpaſmodic action. The retina, after having been excited into action by a ſtimulus greater than the laſt mentioned, falls into various ſucceſſive ſpaſmodic actions. With a greater ſtimulus, the retina falls into a fixed ſpaſmodic action, which continues for ſome days; and a quantity of ſtimulus ſtill greater, induces a temporary paralyſis of the organ of viſion. For the illuſtration of the caſes, with miſcellaneous remarks, we muſt refer to the author's paper, *ubi ſupra*.

SPECULA, among the Romans, were places whence a good view might be had of what was doing at a diſtance. The word is particularly uſed to ſignify watch-towers and beacons.

SPECULARES, in *Natural Hiſtory*, the name of a genus of foſſils of the claſs of the talcs.

The word is derived from the Latin *ſpeculum, a looking-glaſs;* the bodies of this kind being naturally of bright, gloſſy, and poliſhed ſurfaces, and in the thicker maſſes not tranſparent, but reflecting the images of things.

The ſpeculares are talcs, compoſed of viſibly ſeparate plates of extreme thinneſs, and each fiſſile again into a number of others yet finer.

The bodies of this genus are the common Muſcovy talc; the *ſpecularis lucida fuſca*, or brown talc, a ſpecies little inferior to the former in beauty, and found in Germany and England; and the *ſpecularis amethyſtina*, called *talc rouge*, or *red talc*, by the French. This is found in Muſcovy and Perſia, and no where elſe, as far as is yet known, and is often imported into France in maſſes, which are of a beautiful purple: we have of it brought into England, but only in thin flakes, fit for the covering of miniature pictures. In theſe flakes it has none of the redneſs natural to it in the lump, but is the fineſt and moſt tranſparent of all the talcs.

Pliny, and other of the ancient writers, as well as ſeveral of the moderns, uſe the term *ſpecularis lapis* for that ſpecies of talc commonly known by the name of *iſinglaſs*, or *Muſcovy glaſs*.

This has been a ſubſtance in great uſe among mechanics, from the earlieſt times of which we have any account. It is found in broad flat maſſes of ten or twelve inches in breadth, and from half an inch to three inches in thickneſs; and is compoſed in theſe of an almoſt infinite number of broad and beautifully even plates, or flakes, laid with a perfect regularity on one another, and ſeldom parting naturally from each other, though by art they may be divided, almoſt without end, into broad and extremely thin laminæ. Theſe are very flexile and elaſtic, and make no efferveſcence with aqua fortis. By the laſt of theſe properties they are diſtinguiſhed from the plated ſpars which ſome have confounded with them, and by their elaſticity from all other foſſile bodies.

It is found in many parts of the world. The iſland of Cyprus abounds with it. It is very common alſo in Ruſſia, and has of late been diſcovered to abound in the Alps, the Apennines, and many of the mountains of Germany. It is imported in large quantities into England, and is uſed by the lanthorn-makers inſtead of horn, in their nicer works; by the painters to cover miniature pictures; and by the microſcope makers to preſerve ſmall objects for viewing by glaſſes. The ancients uſed it inſtead of glaſs in their windows. Hill's Hiſt. of Foſſils, p. 72.

Some take the lapis ſpecularis to have been a ſpecies of gypſum, and compoſed of the acid of vitriol and calcareous earth. It came into uſe at Rome in the age of Seneca (Ep. 90.), and ſoon after its introduction, was applied not only to give light to apartments, but to protect fruit-trees from the ſeverity of the weather; and it is recorded, that the emperor Tiberius was enabled, principally by its means, to have cucumbers at his table during almoſt every month in the year.

Dr. Watſon apprehends it is ſtill uſed in ſome countries in the place of glaſs; however, it is well known that it was ſo uſed in the time of Agricola, for he mentions (De Nat. Foſ. lib. v. p. 257.) two churches in Saxony which were lighted by it. Agricola eſteemed it to have been a ſpecies of plaſter-ſtone, and in ſpeaking of it he remarks, that though it could bear, without being injured, the heat of ſummer and the cold of winter, yet the largeſt maſſes of it were waſted by the rain. However, it differs from plaſter-ſtone in this property, that it does not, after being calcined and wetted with water, ſwell and concrete into a hard ſtony ſubſtance. Watſon's Chem. Eſſ. vol. ii. p. 297, &c.

SPECULARIA, among the Romans, a kind of window caſements, which were uſed before glaſs was introduced for this purpoſe. They conſiſted of tranſparent ſtones, called *lapides ſpeculares*.

SPECULARIA, the art of preparing and making ſpecula, or mirrors: or the laws of mirrors, their phenomena, cauſes, &c. called alſo *catoptrics*.

SPECULARIS LAPIS, in *Natural Hiſtory*. See SPECULARES.

SPECULATION. — *Certitude of Speculation.* See CERTITUDE.

SPECULATION *Shell*, in *Natural Hiſtory*, a name given by the French writers to a very beautiful ſpecies of the voluta, uſually called by us the Guinea-ſhell, from its being brought from that part of the world.

SPECULATIVE *Geometry*, *Mathematics*, and *Philoſophy*. See the ſubſtantives.

SPECULATIVE *Muſic*. By this expreſſion is uſually underſtood ſcientific muſic, harmonics, the ratio or proportions of ſound; in oppoſition to *practical* muſic, which implies muſic compoſed or performed.

SPECULUM, in *Catoptrics*, is a metallic reflector made uſe of in catadioptric teleſcopes, inſtead of the object-glaſs uſed in dioptric teleſcopes.

Newton. — Mr. Newton, afterwards the celebrated ſir Iſaac Newton, had diſcovered that *light conſiſts of rays differently refrangible*, and that conſequently no figure, which could be given to a ſingle piece of glaſs, would make all the tranſmitted rays concentrate in the focus of that glaſs uſed as an object-glaſs: he relinquiſhed his glaſs-works, and immediately turned his mind to the conſideration of what could be done in the conſtruction of a teleſcope, where the rays of light were made to concentrate by reflection; having previouſly diſcovered and proved, that the angle of reflection of all ſorts of rays was equal to the angle of incidence, without the leaſt perceptible diſperſion. Under an impreſſion that an inſtrument, founded on this baſis, might be made more perfect than could be made with glaſſes alone, when uſed in the uſual way, he tried ſuch metallic ſubſtances as promiſed to produce a hard and bright texture, and to admit of a good poliſh, and in February, 1672, laid before the Royal Society an account of a teleſcope of an entire new conſtruction, that gave a diſtinct image, and magnified or increaſed the viſual angle thirty-eight times. It is ſomewhat remarkable, though not ſo much to be wondered at, when we conſider the genius of the inventor, that this firſt attempt detected not only the beſt materials, but the beſt mode of fuſing and mixing them, if not in the beſt proportions; and left ſucceeding inſtrument-makers little more to do than to vary the proportions, and to exemplify the theory which he pointed out by a ſucceſſion of nice and ſkilful manipulations. Copper, tin, and a portion of arſenic, with ſometimes a little ſilver, were then, as they are at this time, the eſſential ingredients of the compound metal that conſtituted the beſt ſpeculum. The ingenious Huygens was no ſooner informed of the occaſion and ſucceſs of this project, than he calculated and candidly acknowledged the advantage that a good concave ſpeculum muſt have over convex glaſſes in concentrating all the different rays of heterogeneous light. With this firſt inſtrument the ſatellites of Jupiter, as well as the lune of Venus's diſc, were clearly perceived. The ſecond teleſcope, however, was more perfect, and a page of the Philoſophical Tranſactions could be diſtinctly read with it at the diſtance of 100 feet. In this conſtruction, which has obtained the name of the Newtonian conſtruction, there were two ſpecula: one ſpeculum, which was ground to a given radius of curvature, was placed at the end of the tube, which was remote from the object to be viewed, and the other, which was ſmall, was plane, and was fixed in an angle of 45° in the axis of viſion, ſo as to reflect the converging rays to a focus, at the focus of a ſmall eye-glaſs placed at the ſide of the tube, not far from its anterior end or aperture where the eye was ſituated to view the object, that actually lay to the left hand. Caſſegrain in the ſame year communicated to the Royal Society the figure of a reflecting teleſcope, where a perforation in the large ſpeculum admitted the eye-piece to be placed as in the dioptric teleſcope, which he thought had ſeveral advantages, but he did not detail any proceſſes he had uſed towards attaining ſuch a conſtruction; in reply to which ſir Iſaac informed him, that Mr. Gregory had deſcribed a ſimilar conſtruction in his " Optica Promota," in the year 1663, from which reply it ſhould ſeem, that *reflection* had been conſidered by Gregory before ſir Iſaac conſtructed his teleſcope, ſo that the *Gregorian* conſtruction muſt be conſidered as preceding the *Newtonian*, ſo far as relates to the arrangement of its parts; but we are not to conclude from thence, that the beſt compoſition for the ſpeculum was not ſir Iſaac Newton's. During the correſpondence that Huygens had with our author, on the ſubject of a metallic ſpeculum, he took occaſion to obſerve, that no doubt the ſuperiority of a parabolic curve for the face of the reflecting metal over a ſpherical one muſt be known to him, and ſir Iſaac was of opinion that ſome mechanical device might be found out, to produce the deſired curvature, better than any of the *conic ſections;* that is, as we ſuppoſe, better than any *tool* formed agreeably to one of the conic ſections: and with this view Mr. Stephen Gray, we find, preſented a project of forming a grinding tool of a *concatenary* ſhape to be ſubſtituted for the parabola, which, however, did not anſwer in practice. The project was this; a piece of clay was formed thin, when ſoft, into an exact circular cake, and laid on a ſuſpended horizontal rim or ring of a ſmaller diameter, ſo as to allow the cake to aſſume the ſhape of the required curve, which it appeared to do; but on baking this convex cake, it was found to have altered its figure, and to have become flat at the vertex, ſo as to be incapable of becoming a proper bed for the bituminous coat that was intended to receive the emery.

In the teleſcope which ſir Iſaac Newton firſt made, the focal length of the concave ſpeculum was 6$\frac{1}{3}$ inches, that of the eye-piece, which was a plano-convex lens, being juſt $\frac{1}{6}$th; but as the metal was neither perfect, nor very highly poliſhed, he thought that the power ought not to be ſo highly charged for opaque objects, particularly as the aperture was only 1$\frac{1}{3}$d of an inch. Suppoſing the performance of any inſtrument to be known and approved, the author propoſes the ſubjoined table to ſhew what ought to be the apertures, lengths, and powers or charges of other inſtruments to perform equally well. In the firſt column the length of the teleſcope is expreſſed in feet; which quantity doubled gives the ſemi-diameter of the ſphere on which the concave metal is to be ground; in the ſecond column are the proportions of the apertures for theſe ſeveral lengths; and in the third column are the proportions of the charges or diameter of the ſpheres, on which the convex ſuperficies of the eye-glaſſes are to be ground.

Lengths.	Apertures.	Charges.
$\frac{1}{2}$	100	100
1	168	119
2	283	141
3	383	157
4	476	168
5	562	178
6	645	186
8	800	200
10	946	211
12	1084	221
16	1345	238
20	1591	251
24	1824	263

Suppoſe, for example, that a half-foot or ſix-inch teleſcope will magnify diſtinctly 30 times with one-inch aperture, and that it be required to find the dimenſions of an analogous four-feet teleſcope; then oppoſite 4, in column 1, we ſee 476, in column 2; and if 100 at the top of this column be conſidered 1.00, then 476 will be 4.76 for the correſponding aperture; alſo 168, in column 3, will be 1.68 for the charge, producing a magnifying power of 145 times; for if the teleſcope of ſix inches magnify 30 times, the focus of its eye-glaſs muſt be $\frac{1}{5}$th of an inch, and $\frac{168}{500} = \frac{1}{3}$ nearly will be the focal length of the eye-glaſs for 4 feet or 48 inches, and conſequently this number divided by $\frac{1}{3}$ will give 145 nearly for its power. "But what the event will really be," ſays Newton, "we muſt wait to ſee determined by experience." And experience, we may add, has ſhewn, that a four-feet reflector, as now made, with the ſmall ſpeculum alſo concave, will do much more.

Hadley.—From this time we do not find that much, if any, improvement took place in the manipulation of the metallic ſpeculum, till about the year 1719, when Mr. Hadley ſucceeded in making two reflecting teleſcopes of 5 feet 3 inches long; one of which he preſented to the Royal Society of London, and deſcribed in the Philoſophical Tranſactions of March and April, 1723. But though Mr. Pound and himſelf made good obſervations on Saturn, Jupiter, and their reſpective ſatellites therewith, nothing is ſaid about the means uſed in caſting, grinding, and poliſhing either of the ſpecula in queſtion. Dr. Robert Smith, in his "Complete Syſtem of Optics," has, however, ſupplied the omiſſion we have juſt noticed, and has ſtated at conſiderable length how Hadley's method of proceeding was practiſed ſucceſsfully by Dr. Bradley and himſelf at Kew, where, after many trials, they produced their firſt ſpecimen, of 26 inches focal length, in May, 1724. The different proceſſes were now made known to Haukſbee, Scarlet, and Hearne, mathematical-inſtrument makers in London, who, from that period, continued to manufacture this inſtrument for ſale, which before had been made only by and for private individuals.

We will give here only a ſhort detail of the proceſſes uſed by Hadley, Smith, and Bradley, in caſting, poliſhing, and figuring their ſpecula; becauſe the modern improvements in this curious art claim our more particular notice. Having fixed on the radius of curvature, and propoſed diameter, of the large ſpeculum, two arcs were ſtruck with a beam-compaſs on two ſlips of braſs, large enough to receive the curves of the ſame radius as that of the ſpeculum; and when the metal was filed away, ſo that one of the curves was convex, and the other concave, they were ground within one another with fine emery, till they exactly fitted each other, and then became gauges for forming the wooden patterns by, which were next made in a lathe, of ſomewhat larger dimenſions than were required for the ſpeculum, that the rough edges of the caſt-metal might be reduced, as the caſe ſhould require. From this wooden pattern another of pewter, containing about one-tenth of regulus of antimony, was caſt in the uſual way, and turned in the lathe to fit the convex braſs gauge, and to exceed the propoſed ſpeculum by one-twentieth of an inch in thickneſs, and double that quantity in diameter. The flaſks for receiving the pewter pattern, for caſting the ſpeculum by, were of iron, and two inches wider, and one inch deeper, than the pattern, in order that the ſand might be every where an inch thick; and the ingates for receiving the fluid metal were ſo made as to allow four or five ſtreams over the face of the ſand, which was obtained at Highgate. This ſand was neither much wetted, nor rendered too adheſive by an admixture of clay; and when the liquid metal was poured in, the flaſks were ſuffered to remain expoſed to the ſun, ſo as to cool gradually, before the metal was taken out, in order that it might neither warp nor crack. With reſpect to the compoſition of the metal, above 150 different mixtures were tried before one was determined on, which was preferred to ſome of the reſt. One of the metals was three parts of copper and one and a quarter of tin, which was hard and white, but found to be porous, eſpecially if great heat was uſed. Another was ſix parts of Hamburgh plate braſs, caſt and milled, with one part of tin only; but the fumes of the calamy ſtone left ſcabrous ſtreaks on the ſurface. A third metal, therefore, compoſed of two parts of the former of theſe compoſitions, and one of the latter, was adopted, as being ſuperior to either; but it was found neceſſary that the copper and braſs ſhould be melted together ſeparately, before the tin was melted and poured in. And much importance was attached to the immediate pouring out of the whole mixture, as ſoon as it could be well ſtirred: for after cooling, leſs heat was neceſſary to melt the whole mixture, than was ſufficient to fuſe one of the ingredients alone; and the leſs heat was uſed in bringing the maſs into a liquid ſtate, the leſs porous the ſpeculum was found to be, when poliſhed. After the metal thus caſt had become cool, it was firſt ground on a common grinding-ſtone a little concave, till all the ſand-holes and inequalities were taken off; and then a ſmaller grinding-ſtone, or a piece of one, was ſhaped ſo convex as to fit the braſs concave pattern, on which the metal was again ground, when fixed upon a block, with a little emery and water, till the gauge fitted it. The diameter of the rough ſtone was to the diameter of the ſpeculum as 6 to 5. When the ſtrokes in grinding were made in a circular direction, they diminiſhed the edges of the ſtone; but when made acroſs, they made it flatter, ſo that it might be made a portion of either a ſmaller or larger ſphere, by the mode of working, and conſequently might be made to grind the concave ſpeculum accordingly. But care was taken that as little of the external hard cruſt was ground away as poſſible, when the figure was once complete, and the ſurface even. When the rough grinding was finiſhed, various other tools were uſed, not only with the ſpeculum, but with each other, to inſure an uniformity of ſhape. A braſs concave tool, ſhaped like the ſpeculum, but of larger diameter, was worked on a marble convex tool, on which were bedded by cement a number of ſmall blue hones, like a pavement; ſo that the working of the braſs concave tool on this pavement made a convex curve over the ſurface of the pavement, which was thus prepared to ſmooth the ſpeculum ſtill further, as well as to improve its figure, by varying the mode of applying the grinding ſtrokes. Again, a poliſhing tool made convex, of glaſs or fine marble, and brought to its figure by the braſs concave tool, was covered with a piece of fine even ſarcenet, and laced tight behind, on which a ſolution of pitch in ſpirits of wine was ſpread evenly with a varniſh bruſh, till its conſiſtence was uniform, and thick enough to receive a portion of fine putty powder, when another tool, made concave of braſs, called a *bruiſer*, was uſed to rub down the gritty matter of the putty occaſionally, as well as to grind ſometimes the bed of hones, when its figure began to alter too much. During the grinding, a wooden handle was cemented on the central part of the ſpeculum, to move it by. It would be tedious to detail all the variety of precautions, with the ſucceſſion of circular, ſpiral, and croſs ſtrokes, recommended for giving perfection to the figure and poliſh of the metal; all which the reader may find in Smith's Optics, from page 301 to page 312, together with the author's mode of examining both the exact length of the focus, and the figure of the curve, by the reflected light of a candle.

In reflecting teleſcopes of various lengths, a given object will appear equally bright and equally diſtinct, when their linear apertures, and alſo their linear amplifications, or magnifying powers, are as the ſquare-ſquare roots of the cubes of their lengths, agreeably to both ſir Iſaac Newton and Dr. Smith. For example, ſuppoſe that a reflecting teleſcope, with an aperture of 2.448 inches, have a ſpeculum of two feet focal length, and an eye-glaſs of $\frac{236}{1000}$th of an inch focus, where the power will be $\frac{24}{.236} = 102$, and that it be required to have another made of three feet focal length, that ſhall produce the ſame brightneſs and diſtinctneſs in the object viewed; firſt we ſhall have $2 \times 2 \times 2 = 8$ for the cube, and the ſquare root of $8 = 2.83$, and again the ſquare root of $2.83 = 1.68$; then $3 \times 3 \times 3 = 27$ is the cube of the new focal length, and 5.2 its ſquare root; and again, the ſquare root of 5.2 will be 2.28; hence, as 1.68 : 2.28 :: 102 : 138; therefore 138 will be the magnifying power of the enlarged teleſcope, 0.261 the focus of its eye-piece, and 3.312 inches its correſponding aperture; for as 1.68 : 2.28 :: 2.448 : 3.312, &c.; and alſo $\frac{36}{138} = 0.261$.

The following table, conſtructed on this propoſition, was calculated by Dr. Smith, which we inſert, as being in a form more intelligible to a common workman, than the one we have before inſerted from the calculation of ſir Iſaac Newton.

Focal Diſtance of Speculum.	Focal Diſtance of Eye-Glaſs.	Magnifying Power.	Aperture.
Feet.	Inches.		Inches.
½	0.167	36	0.864

This table is adapted for teleſcopes of the Newtonian conſtruction, in which the figure of the great metal is ſuppoſed to be truly ſpherical; but it is preſumed, that when this table ſuppoſes the conſtruction to be of the Gregorian kind, the focal length is the ſum of the focal lengths of both the ſpecula, or the diſtance that the rays paſs after both reflections, before they come to the eye-glaſs; and that the large ſpeculum is parabolical.

Short.—We do not find that any optician diſtinguiſhed himſelf in the art of making ſpecula for reflecting teleſcopes, after Dr. Smith's time, till we come to Mr. James Short, whoſe compoſition was beautiful, and whoſe poliſh, as well as parabolic figure, were excellent; nay, have been conſidered as ſtandards of perfection for even ſubſequent opticians to imitate. We have, however, to regret that this conſummate workman not only kept his proceſs a ſecret from the other opticians, but, in order to ſecure to himſelf the fame he had acquired of being the firſt in his line of manufactory, ſome little time before his death, as we are credibly informed, he employed his founder, Mr. Juſtice Blackburgh, to deſtroy all his tools, leſt they ſhould fall into ſome perſon's hands, who might avail himſelf of their uſe; and accordingly they were all melted into a liquid maſs: and his long and ſucceſsful experience has no further benefited poſterity, than as it left ſpecimens of workmanſhip to ſhew what ſkilful perſeverance could effect.

Short left behind him, however, a table of the apertures, powers, and prices, of reflecting teleſcopes, conſtructed by him in the Gregorian form; which, not being generally known, we ſhall ſubjoin, by way of effacing the blot on his memory.

Numbers.	Focal Length in Inches.	Diameter of Aperture in Inches.	Magnifying Powers.		Price in Guineas.
1	3	1.1	1 power of	18 times.	3
2	4½	1.3	1	25.	4
3	7	1.9	1	40.	6
4	9½	2.5	2	40, and 60.	8
5 }	12	3.0	2	55, and 85.	10
6 }	12	3.0	4	35, 55, 85, and 110.	14
7	18	3.8	4	55, 95, 130, and 200.	20
8	24	4.5	4	90, 150, 230, and 300.	35
9	36	6.3	4	100, 200, 300, and 400.	75
10	48	7.6	4	120, 260, 380, and 500.	100
11	72	12.2	4	200, 400, 600, and 800.	300
12	144	18.0	4	300, 600, 900, and 1200.	800

In this table Mr. Short *always* overrated the *higheſt* power of his teleſcopes, according to the authority of the Rev. John Edwards, of whom we ſhall have occaſion to ſpeak hereafter; and to this circumſtance alone, we are aſſured by an ingenious and candid optician, it is to be aſcribed, that all following opticians have been obliged, by way of ſatisfying the expectations of their cuſtomers, to overrate the higheſt power of their teleſcopes, in order to obtain a price adequate to their reſpective values. Experimental meaſurements, indeed, ſoon detect this falſe repreſentation; and it would be to the credit of opticians, if they would agree to fix a true meaſure to each power of their teleſcopes, and to ſell them, notwithſtanding, at their accuſtomed prices: for then their purchaſers would not experience diſappointment.

Short made two or three Gregorian teleſcopes of 18 inches focus, with 4.5 inches aperture, and power 170; and half a dozen of 24 inches focus, with 6 inches aperture, with the uſual magnifying powers; but one of a Caſſegrain form, with a convex ſmall ſpeculum, of the ſame dimenſions, intended to have a power of 355, was not diſtinct, and would bear only a power of 231.

Mudge.—In the year 1777, Mr. John Mudge produced a paper to the Royal Society, which is printed in their 67th volume, entitled "Directions for making the beſt Compoſition for the Metals of reflecting Teleſcopes; together with a Deſcription of the Proceſs of grinding, poliſhing, and giving the great Speculum the true parabolic Curve." It will be ſufficient for our preſent purpoſe, if we ſhew in what reſpects Mr. Mudge's metal differs from that which we have juſt deſcribed, and in what his improvements in caſting conſiſt. In the firſt place, Mr. Mudge attempted to aſcertain what metals, and proportions of thoſe, will produce a compoſition that has the three requiſites of extreme hardneſs, whiteneſs, and compactneſs, or exemption from poroſity. The firſt two qualities, after many experiments, he found were united in a mixture of 14½ ounces of grain-tin with two pounds of good Swediſh copper; but the quality of compactneſs was not to be acquired from the mixture ſimply conſidered: it was produced principally from the manner in which the mixture was made. It had been uſual to melt the copper firſt, and then to add the tin, and to pour the liquid mixture, with the ſcoria firſt taken off, into the flaſks, to form the ſpeculum in the firſt melting; but the metal generally turned out to be porous, when poliſhed. Mr. Mudge, on conſidering that putty is tin calcined, began to think, that part of the tin melted in a high heat might be converted into putty, and that the pores might ariſe from this cauſe; he, therefore, poured out the liquid compound to form an ingot, which would fuſe with a lower heat than the copper alone required; and on uſing this metal a ſecond time, fuſed with a moderate heat, it was generally, if not always, found compact. Thus melting a ſecond, or even a third time, proved to be a remedy againſt poroſity; and it was afterwards found, that if an ounce of the tin was reſerved to be put into the mixture at the final melting, the brilliancy of the metal was thereby increaſed. If a ſpoonful of charcoal duſt be thrown into the crucible, before the metal be ſtirred with a wooden ſpatula, and poured into the moulds, Mr. Mudge ſays that the metal will be found to have a cleaner ſurface, than when no ſuch duſt is uſed. For Mr. Mudge's method of grinding, poliſhing, and figuring his ſpecula, ſee our article GRINDING.

Edwards.—In the Nautical Almanac of the year 1787 is printed a memoir, entitled "Directions for making the beſt Compoſition for the Metals of reflecting Teleſcopes, and the Method of caſting, grinding, poliſhing, and giving the great Speculum the true parabolic Figure," by the Rev. John Edwards, B.A., of Ludlow. Theſe directions having been conſidered an improvement on Mr. Mudge's, in ſeveral reſpects, were publiſhed firſt in a pamphlet, which was ſoon bought up by the trade; but at the requeſt of the compoſer of the preſent article, they were reprinted in Nicholſon's Philoſophical Journal, vol. iii. 8vo. Series, p. 490, et. ſeq., in the year 1800; but with the omiſſion of a portion of the appendix.

After what we have already ſaid on this ſubject under our article GRINDING, as well as in the preceding part of our preſent article, it will not be neceſſary to give the whole of Mr. Edwards's memoir, but to dwell more particularly on thoſe methods of proceeding which are peculiarly his own, and which conſtitute his acknowledged improvements. The firſt object that Mr. Edwards had in view was, like that of his predeceſſors, to aſcertain, by a number of trials of various mixtures, made from the metals and ſemi-metals, what compoſition is, on the whole, to be preferred: for which purpoſe he tried ſilver, platina, iron, copper, braſs, lead, and tin, crude antimony, regulus of antimony, martial regulus of antimony, arſenic, biſmuth, zinc, and antimony combined with cawk-ſtone; and in the appendix to his memoir he gave the reſult of 71 mixtures, which we will here tranſcribe, in order that the ſame experiments may not be fruitleſsly repeated by future mechanicians.

1. Copper and grain-tin, equal parts; very bad, ſoft, and of a blue colour.
2. Copper with arſenic $\frac{1}{8}$; but little different from the firſt.
3. Tin 2, copper 1; much worſe than the preceding ones.
4. Copper 32, tin 16, arſenic 4, fixed with nitre; black and brittle.
5. Copper 6, tin $1\frac{3}{4}$, arſenic 1; very indifferent.
6. Copper 32, tin 14, arſenic 2; a very good metal.
7. Copper 32, tin $13\frac{1}{2}$, arſenic 1; not quite ſo good as the ſixth.
8. Copper 32, tin $13\frac{1}{2}$, arſenic $1\frac{1}{2}$; a good metal.
9. Copper 32, tin 15, arſenic 2; much better than any of the above.
10. Copper 6, tin 2, arſenic 1; compact, but very yellow when poliſhed.
11. Copper 3, tin $1\frac{1}{4}$; compact, and whiter than the tenth.
12. Copper 32, tin $14\frac{1}{2}$; a pretty good metal, but poliſhes too yellow.
13. Copper 32, tin 15, arſenic 2, flint-glaſs in powder 3; very bright, but rotten.
14. Braſs 6, tin 1; compact, but too yellow.
15. Two parts of the eleventh compoſition, and one part of the fourteenth compoſition; compact, but much too yellow when poliſhed.
16. Braſs 5, tin 1; ſomewhat whiter than the fourteenth.
17. Braſs 4, tin 1; a good metal, but rather yellow.
18. Braſs 4, tin 1, with arſenic $\frac{1}{10}$; whiter than the ſeventeenth.
19. Braſs 3, tin 1; will not poliſh well.
20. Braſs 2, tin 1; of a ſparry nature.
21. Tin 3, braſs 1; too ſoft, being only a kind of hard pewter.
22. Braſs and arſenic, equal parts; a dirty white colour.
23. Braſs, copper, and arſenic, equal parts; a dingy white.
24. Braſs and platina, equal parts; very difficult to fuſe and mix well together, is then malleable, and of a dingy white colour, like the twenty-ſecond compoſition.
25. Copper 32, tin 14, crude antimony 4; black and rotten.
26. Copper 32, tin 14, crude antimony 1; blueiſh, and rough-grained.
27. Copper 32, tin 15, arſenic 4, biſmuth 2; much too rotten.
28. Copper 32, tin 15, arſenic 3, biſmuth 1; much too yellow when poliſhed, and appears alſo porous.
29. Copper 2, zinc 1; a pale malleable metal.
30. Copper and zinc, equal parts; ſtill malleable and rough-grained.
31. Copper 32, tin 15, arſenic 4, zinc 4; a good metal, but does not take a high luſtre.
32. The thirty-firſt compoſition, fluxed with corroſive ſublimate; a compact and hard metal, but rather yellow when poliſhed.
33. Copper 32, tin 16; a moſt beautiful brilliant compoſition, but much too brittle and rotten.
34. Copper 32, tin 17; blueiſh and rough-grained.
35. Copper 32, tin 18; blueiſh and rough-grained
36. Braſs 2, zinc 1; nearly of a gold colour.
37. Braſs and zinc, equal parts; a pale gold colour, and rough-grained.
38. Spelter 4, tin 1; very rotten.
39. Copper and crude antimony, equal parts; of a ſparry nature.
40. Copper 32, tin 15, arſenic $\frac{1}{4}$th of the whole; a very beautiful and brilliant metal, but tarniſhes when expoſed for ſome time to the air.
41. Silver and biſmuth, equal parts; a yellowiſh-white metal, and not much harder than ſilver itſelf.
42. Silver and tin, equal parts; a white metal, almoſt like ſilver itſelf, and much too ſoft for ſpecula.
43. Silver, tin, and biſmuth, equal parts; a dingy white colour, but much harder than the two preceding compoſitions.
44. Copper 32, tin 15, ſilver 1; a beautiful compact metal, but poliſhes rather too yellow.
45. Copper 32, tin 15, ſilver 2; not ſo white as the preceding.
46. Copper 32, tin 16, braſs 4, arſenic 2; rather too much tin, as the compoſition was of a blueiſh complexion, and rough-grained.
47. Copper 32, tin 15, braſs 1, ſilver 1, arſenic 1; a moſt excellent metal, being by much the whiteſt, hardeſt, and the moſt reflective I have ever yet met with.
48. Common bell-metal; poliſhes very yellow.
49. Common bell-metal 4, regulus of antimony 1; blueiſh and rough-grained.
50. Common bell-metal 6, regulus of antimony 1; ſtill blueiſh and rough-grained.
51. Copper 32, tin 14, regulus of antimony $1\frac{1}{6}$, *viz.* 1 oz. to 1 lb.; too much antimony, it being of a blueiſh colour, and rough-grained.
52. Copper 32, tin 13, regulus of antimony $\frac{1}{16}$; blueiſh and rough.
53. Copper 32, tin 13, regulus of antimony $\frac{1}{32}$, *viz.* 1 oz. to 2 lb.; a very fine metal, in appearance like thirty-three.
54. Copper 32, tin 13, regulus of antimony $\frac{1}{40}$, *viz.* 1 oz. to $2\frac{1}{2}$ lb.; a beautiful metal, not much unlike forty-ſeven, but not quite ſo white.
55. Crude antimony 16, cawk-ſtone 1 or 2 oz.; a very bright glaſſy metal, like the common vitrum antimonii, but by no means fit for mirrors.
56. Copper 32, tin 16, vitrum antimonii made from the cawk-ſtone 1 oz.; a very indifferent compoſition, as the vitrum antimonii did not differ in its effects from crude antimony.
57. Copper 32, tin 14, lead 2; no art can make this compoſition mix intimately, as the lead will always ſeparate from the copper and tin.
58. Copper 32, tin 16, regulus of antimony 3; black, and much too rotten.
59. Copper 32, tin 16, iron-filings 8; a blueiſh-grey colour, and rough-grained, and appeared ſomewhat like ſteel when broken through.
60. Fifty-ninth compoſition 8 oz., tin 1 oz.; a little whiter than the fifty-ninth, but ſtill too blue.
61. Equal parts of fifty-nine and ſixty; ſtill of too blue a colour, and not cloſe-grained.
62. Copper 32, tin 16, arſenic 3, iron-filings $\frac{1}{4}$ of an oz.; a pretty brilliant compoſition, but much inferior to forty-ſeven.
63. Platina 1 oz., braſs 1 oz., cawk-ſtone red-hot $\frac{1}{2}$ oz.; exceſſively difficult to fuſe, and of a dirty light brown colour, and ſomewhat malleable.
64. Copper 32, tin 16, iron-filings 4, regulus of antimony 4, and fluxed with corroſive ſublimate; an exceeding hard and compact metal, but of too blue a colour.

65. Copper 2 oz., tin 1 oz., iron-filings 1 dr., regulus of antimony 1 dr.; too blue a colour, and rough-grained.

66. Regulus of antimony and tin, equal parts; ſparry, and not fit for mirrors.

67. Caſt-ſteel; will not poliſh upon pitch, either with putty, or colcothar of vitriol.

68. Steel 1, tin $\frac{1}{4}$; very rough-grained and blueiſh, and not much different from ſteel itſelf.

69. Steel 1, tin 1; rough-grained, and of a blueiſh colour.

70. Steel 1, and forty-ſeventh compoſition 20 parts; rough-grained, and not near ſo good as forty-ſeven.

71. Steel 1, and forty-ſeventh compoſition 30; not much different from the forty-ſeventh compoſition, but not ſo beautiful and cloſe-grained.

"Many other mixtures," ſays Mr. Edwards, "were tried, by combining the foregoing compoſitions in more than a hundred varieties of proportions; but none of them were found equal to N° 47, as that mixture forms a metal that is the whiteſt, hardeſt, moſt reflective, and takes the higheſt luſtre of any thing I have yet ſeen."

The mixture, therefore, which was at laſt choſen from theſe various experiments, was 32 ounces of pure copper, with 15 or 16 of grain-tin, juſt enough to ſaturate the copper, 1 of braſs, and 1 of arſenic; which compoſition will be ſtill further improved, it is ſaid in a note, but we believe not correctly, by 1 of ſilver. The uſe of the copper was to leſſen the extreme brittleneſs of the mixture; the arſenic rendered the metal cloſe and free from pores; and the ſilver, it was thought, improved the brightneſs, without injuring the hardneſs, when uſed in a ſmall quantity. This mixture, it will be remarked, very much reſembles Mr. Mudge's, who uſed 14½ of grain-tin to 32 of copper, but without arſenic, or other addition: he found 15 *too hard* for the blue ſtone to take hold of; but Mr. Edwards availed himſelf of another ſtone, procured at Edgedon, in Shropſhire, ſituated between Ludlow and Biſhop's Caſtle, which was keen enough to bite a metal with from 15 to 16 of tin to 32 of copper, which compoſition Mr. Mudge conſiders to poſſeſs a *maximum* of whiteneſs as well as of hardneſs. Mr. Mudge, however, ſays, that one of his beſt workmen, called Jackſon, found a ſtone that would cut a metal of one-third tin and two-thirds copper, but the diſcovery of ſuch ſtone, which he always kept a ſecret, coſt him the expence of a journey of two hundred miles; which diſtance exceeds that of Edgedon from London, by about fifty miles; and, therefore, the ſtones of Jackſon and of Mr. Edwards were probably not from the ſame quarry, if they were ſimilar in kind. Edwards's mode of caſting is nearly the ſame as Mudge's, both as to a firſt fuſing for the ingot, with a ſecond fuſing for the ſpeculum at a lower heat; and as to his flaſks and ſand (procured from Highgate), a ſmall portion of the tin was alſo reſerved to be put into the crucible at the ſecond melting, when alſo the arſenic, tied up in paper, was put in; and after the fumes of this ingredient had ceaſed to aſcend, the mixture, ſtirred with a wooden ſpatula, while no breath was inhaled into the lungs, was poured into the flaſks, the moment that about an ounce of powdered reſin, or reſin and nitre, had been thrown in and melted, to give a good face, as Mudge did with the charcoal duſt. The principal difference from Mudge's proceſs is, that in the firſt melting, after the braſs is made as fluid as poſſible, the braſs and ſilver muſt be added with the common black flux, of two parts of tartar to one of nitre, or by ſtirring the melted mixture with a ſpatula of birch; after which the tin muſt be added, and the whole poured out into an ingot, as ſoon as it is found to be in a liquid ſtate; and after the ſecond melting, when the arſenic has been added, and alſo the reſin, the flaſks receive the metal, with the face downwards; the ingate having been made on the back of the metal near its edge, and its breadth increaſing to half the diameter of the metal at the place of joining. The upper part of the ingate ſhould contain as much metal in weight as the ſpeculum and the flaſks ſhould be opened, and the ſand cleared out, while it remains red-hot, with the face ſtill downwards, and then removed by a pair of tongs into an iron pot, containing a large quantity of hot aſhes or ſmall coals, ſufficient to bury the metal, where it muſt remain to cool by degrees with the aſhes. We muſt not, however, omit to mention one precaution, on which ſome ſtreſs ſeems to be laid, *viz.* that when the pattern, with its ingate, or git, is taken out of the ſand, ten or a dozen ſmall holes muſt be made through the ſand at the back of the mould, with a ſmall wire, or common knitting-needle, to permit the air to eſcape while the liquid metal is filling the mould, which are ſafer than one large hole: alſo at the ſecond melting, the flaſks muſt be jogged with a ſlight ſtroke or ſhake, as ſoon as the fluid metal is poured in, to prevent flakes or air-bubbles being formed on the face of the metal. The git may be taken off, when the metal is quite cool, with a common fine half-round file, to make an inciſion, after which a gentle blow will remove it. If, however, the metal is caſt from a mould too thick, it will not take the parabolic figure. For a ſpeculum of 4½ inches diameter, and 18 inches focal length, the thickneſs ſhould be $\frac{4}{10}$ths of an inch at the edge, and the back ſhould be convex, ſo as to allow the whole metal to be of uniform thickneſs when ground, in order that it may not yield to the preſſure, or incumbent weight, during the grinding and poliſhing. The handle ſhould be made of the ſame concavity and convexity as the metal, but double its thickneſs, and only three-fourths of its diameter; it ſhould alſo have a hole through the centre, to receive a ſcrew going into the chuck of a lathe, in order that the edge of the metal may be formed, firſt by a file, and then by a ſtone from Edgedon, while it is revolving.

The ſpeculum being caſt by theſe directions, is next rough-ground on a common grinding-ſtone, formed by a bar of ſteel, while revolving, to the radius of convexity ſuitable for making the deſired concavity of the metal; after this rough-grinding, two tools are all that are requiſite; a convex tool made of lead and tin, or elſe of pewter, and a bed of hones, of the ſort already mentioned; for the convex tool ſerves alſo for a poliſher, in conjunction with its coat of pitch and *colcothar of vitriol*, which is preferred to putty: the poliſh from the latter is indeed of a white ſilvery hue, but that from the former gives a fine dark luſtre, like the complexion of poliſhed ſteel, which is deemed preferable. The colcothar, to be good for this purpoſe, muſt be of a deep red or purple colour, muſt diſſolve in the mouth without gritty lumps, and feel ſoft and oily to the touch. It may be levigated with a little water between two bars of poliſhed ſteel, and worked with two or three additions of water, till it acquires a dark and nearly black colour, when it will be fine enough to be put into a bottle with water for uſe. We will not repeat all the proceſſes to be attended to in the uſe of the convex tool, and of the bed of hones, which we have ſufficiently detailed under our article GRINDING, but remark only on their dimenſions and ſhape, which form eſſential conſiderations in Mr. Edwards's mode of grinding, poliſhing, and particularly of giving the requiſite figure without a ſucceſſion of tentative operations. The bed of hones ſhould be of a circular figure at the circumference, and in every reſpect the ſegment of a ſphere, with a diameter juſt $\frac{2}{10}$ths of an inch wider than that of the metal, when it is four or five inches in diameter; and the reaſon is, that if it is much larger, it will enlarge the circle of concavity of the metal worked on it. The convex tool muſt not, however, exceed the ſpeculum in diameter more than $\frac{1}{10}$th of an inch, otherwiſe it will enlarge the radius of concavity too much. Much water uſed with the bed of hones is detrimental to the figure, and therefore muſt be avoided in bringing out the ſcratches of the grinding-ſtone, and in producing a true ſpherical face. We have ſaid nothing hitherto of the *ſhape* of the rough grinder, or convex tool, to be uſed alſo as a poliſher; this muſt be *elliptical* at its circumference, and the longer diameter muſt be to the ſhorter exactly as 10 to 9, the latter being juſt equal to the diameter of the ſpeculum to be ground and poliſhed by it. This proportion has been found by experience to give the *parabolic* figure in ſpecula of ordinary dimenſions, by the common mode of uſing the tool in all directions; which diſcovery by Mr. Edwards gives him a claim to originality of method, as well as of ſimplicity and certainty in the operations, independently of ſuperior ſkill in the operator. This elliptical tool is uſed firſt after the grinding-ſtone with fine emery and water, before the bed of hones, and again with the colcothar and water as a poliſher, and during the latter operation, it is ſaid to give alſo the parabolic figure. The preparation of this elliptical convex tool, as a poliſher, is thus effected. The pitch is made by boiling tar in a ladle or crucible over a very ſlow fire, till it is very hard when tried cold, and with this an equal quantity of reſin is melted, which prevents too much brittleneſs, and makes a good, hard, unelaſtic coat for the reception of the colcothar. With regard to the requiſite *hardneſs* of the pitch, Mudge and Edwards ſeem to differ in opinion; but as the metal of Edwards is harder than that of the other, and as he uſes a different powder for the poliſh, each opinion may be well founded, ſo far as relates to his own mode of poliſhing. The pitch, or pitch and reſin, being melted in a crucible, is poured on the heated elliptical tool, and ſpread to the thickneſs of a half-crown, with an iron ſpatula; when it is cooled a little, a ſheet of writing-paper is laid on it, and is preſſed equably with the concave face of the ſpeculum itſelf, which does the work of Mudge's concave tool in this reſpect; and when the paper is removed, it will be ſeen, by the fine furrows of its face made thereby, whether or not the impreſſion of the ſpeculum has, at the firſt trial, given its counterpart to the pitch all over; if not, a ſecond impreſſion muſt be taken in like manner, after the pitch has been ſoftened a little before a fire; otherwiſe the face of the ſpeculum might have been dipped in water, to prevent adheſion, and then the paper might have been diſpenſed with. The ſuperfluous pitch muſt now be removed from the edge of the elliptical poliſher, and a cone of wood inſerted into its central ball, to make it perfectly round, like the hole of the metal before the coating was poured on. The pitch is next ſaturated with the colcothar and water, and then poliſhing commences, and is continued, without any particular attention to the ſtrokes, more than is neceſſary for giving the poliſh, and when that is finiſhed by croſs ſtrokes given in all directions, as uſual, the parabolic figure is enſured by the variable dimenſions of the poliſher's diameter. Laſtly, the final poliſh is nearly attained when black mud is generated quickly on the ſurface of the metal, which muſt be partially, but not entirely, wiped off at intervals, till the buſineſs is finiſhed, when the truth of the figure and goodneſs of the metal may be put to the proof that we have deſcribed in our former article, as recommended by Mr. Mudge; or may be tried by Edwards's more convenient teſt, which we ſhall preſently deſcribe.

Since we made the preceding abridgment of Edwards's directions, we have ſeen an extract from one of his letters to Dr. Maſkelyne, containing *an addition* to his former directions, which, as it is ſhort, we will here ſubjoin. "Make the brilliant compoſition firſt of copper and tin. Melt the proportional quantity of ſilver and braſs in a ſmall crucible by itſelf. When you put the brilliant compoſition the ſecond time into the crucible, add alſo the lump of braſs and ſilver melted together before in a ſeparate crucible; and when the whole is now fluid, add the proportional quantity of arſenic, and then pour it off into the flaſks, after the ſcoria is taken off, and a little powdered reſin is thrown into it." The reaſon aſſigned is, that as copper requires more heat to melt it, than either ſilver or braſs does, if the braſs were put into the high heat of melting copper, its lapis calaminaris would calcine, which will not be the caſe when the ingot is made liquid by the lower heat of the ſecond melting. The beſt fuel that Edwards found for melting the metal was coal-coke, as prepared by the maltſters, which caſts no ſmoke, and is more laſting than charcoal: he alſo found, that the blueiſh hue of crown-glaſs uſed for the eye-piece, beſt corrects the yellowiſh colour of objects, as ſhewn by a ſpeculum, and particularly when N° 47 is the compoſition choſen. In trying the figure of the great ſpeculum, Mr. Edwards rejects the diaphragms of Mr. Mudge as unneceſſary, and adopts a more ſimple method, thus; when the ſpecula and eye-piece are in their places, he fixes a circle (of white paper probably) of half an inch, or an inch in diameter, at the diſtance of from fifty to one hundred yards, and gives it a broad black annular margin, by way of contraſt; then, when the teleſcope is adjuſted nicely to diſtinct viſion thereby, the ſcrew that moves the ſmall mirror muſt be turned either way, until a *dark haze* ſurrounds the circle, (or field of view,) which will become broader and broader the further the ſcrew is turned; now, if the haze is more diſtinct, and the edge of it better defined when the ſcrew turns to the right hand, or brings the ſmall ſpeculum nearer, from the point of diſtinct viſion, than when the motion is in a contrary direction, the figure of the great ſpeculum is *ſpherical;* but if, on the contrary, the edge of the haze is better defined by the oppoſite motion, then the figure is *hyperbolical;* and, laſtly, if at equal diſtances on each ſide of the true focal point the appearance of the haze is the ſame, the figure is known to be properly *parabolic*, and fit for its office. The ſmall ſpeculum, in the Gregorian conſtruction, being placed to receive converging rays from the large one, is required to be ſpherical, as we have before ſaid; but in the Newtonian conſtruction it is made plane, and of an oval ſhape, to reflect the rays to the eye, placed at an angle of 90°. Mr. Edwards ſays, he received his inſtruction how to grind and poliſh one of theſe from his friend, Mr. (now Dr.) Herſchel, when he lived at Bath. To grind one of the *elliptical* ſpecula *flat*, a ſmall tool of lead with emery is firſt uſed, and then two or more conſiderably larger ones are uſed; both the tools and bed of hones ſhould not be leſs than ſix inches in diameter. The figure of the tools is not conſidered to be completed, till the ſpeculum can be firſt highly finiſhed upon one of them, and afterwards be applied to another, without receiving any change: the laſt half dozen ſtrokes ſhould be in the direction of the longer axis of the ellipſis. When this is perfected, it muſt be poliſhed upon the pitch-poliſher, of a circular form, the diameter of which is greater than the tranſverſe axis of the ſpeculum by *one-tenth*. As Mr. Edwards ſpeaks of Mr. (Dr.) Herſchel as his friend; and as the doctor has not, that we know of, yet publiſhed the compoſition of his metal and mode of grinding, poliſhing, and figuring it; we may conclude that he practiſes Mr. Edwards's proceſs, and particularly as Mr. Edwards gives us the following information in the poſtſcript of his pamphlet. "Mr. Herſchel chiefly makes uſe of a Newtonian reflector, the focal diſtance of whoſe great mirror is ſeven feet, its aperture 6.25 inches, and powers 227 and 460 times, though ſometimes he uſes a power of 6450 for the fixt ſtars. Note, if the metals of a Newtonian teleſcope are worked as exquiſitely as thoſe in Mr. Herſchel's ſeven-feet reflectors, the higheſt power that ſuch a teleſcope ſhould bear, with perfect diſtinctneſs, will be given, by multiplying the diameter of the great ſpeculum by 74; and the focal diſtance of the ſingle eye-glaſs may be found, by dividing the focal diſtance of the great mirror by the magnifying power: thus, $6.25 \times 74 = 462$, the magnifying power; and

$$\frac{7 \times 12}{462} = 0.182$$ of an inch, will be the focal length of the ſingle eye-glaſs required." When we arrive at our article Telescope, we truſt that we ſhall be able to lay before our readers more minute information reſpecting the ſpecula, as well as other parts of Dr. Herſchel's wonderful inſtruments, than we have room for in our preſent article.

Suppoſing now Mr. Edwards's ſpecula to be finiſhed, it remains that we ſay a few words reſpecting his mode of fixing them in his tube, to give a diſtinct image of the object to be viewed, without which they would be uſeleſs. When the large ſpeculum is made to reſt againſt the inner end of the tube for which it is adapted, the arm which carries the ſmall ſpeculum muſt be firſt adjuſted: in order to do this properly, extend firſt two fine threads, or wires, acroſs the aperture of the tube at right angles, ſo as to interſect each other exactly in the axis of the tube; before the arm is finally faſtened to the ſlider, place it in the tube, and through the eye-piece, without glaſſes, let the eye be directed to the ſcrew-hole in the end of the arm, and if the point of interſection of the croſs-wires be at its centre, the hole is in the axis, but not otherwiſe. When this exactneſs is obtained by mechanical means, the arm may be there made faſt to the ſlider. In the next place, the ſmall ſpeculum muſt be placed parallel to the large one, thus; cut a piece of card into a circle about one-half or two-thirds of the diameter of the mouth of the tube, and fix it concentrically at the mouth with a piece of ſtick, that ſhall biſect the tube, to the middle of which the circular cord may be tied, ſo as to exclude all the light, except an annular portion at the circumference of the tube; this being done, turn the teleſcope to the ſky, and the annular light that falls on the great ſpeculum will be reflected on the little ſpeculum, on which it will form an annular light alſo of ſmaller dimenſions. Now, if the breadth of this ſmall ring of light is obſerved to be equally broad at every ſide of the ſmall ſpeculum, the poſition thereof is parallel to that of the large one, but if not, it muſt be adjuſted till this is the caſe. But it may ſo happen, that this adjuſtment may put the centre of the ſmall ſpeculum out of the axis of the tube, which may be detected thus; examine again the annular light, and take notice whether or not the ring is *concentric* with the circumference of the metal; if not, it muſt be made ſo by the ſcrews of adjuſtment, or otherwiſe. In order to be certain that theſe adjuſtments of the ſmall ſpeculum are accurate, turn the teleſcope again to the ſmall circle of paper with a black margin, with the tube quite open, and having made its image concentric with the ſmall ſpeculum at the point of diſtinct viſion, alter the focus by moving the ſmall ſpeculum gradually, till the black margin becomes a black ſpot, or point; and if this ſpot lie on the centre of the ſmall ſpeculum apparently, the two adjuſtments, for the axis of viſion, and for paralleliſm, are both correct. Again, if a ſtar of the firſt magnitude appear perfectly round and well defined; and alſo if the ſmall ſtars, in the double ſtars, are well ſeen, theſe are proofs of the excellence not only of the figure and poliſh of the metal, but likewiſe of all the adjuſtments.

We have only to add further to what we have ſaid of Edwards's metal and proceſs, that on conferring lately with ſome of the moſt eminent opticians of the preſent day, their opinion is, that reflecting teleſcopes are brought as near to perfection as art and experience can effect, by Watſon, Tulley, and others, but that it is not neceſſary to adhere rigidly to Mr. Edwards's, any more than to Mr. Mudge's directions; the Edgedon ſtones, for inſtance, do not anſwer the deſcription given of them for cutting the hardeſt metals, which are always the beſt when the colour is proper; (the denſity of which, we underſtand, may be determined by their ſpecific gravity, without the trouble of previous poliſhing); neither is a bed of hones indiſpenſably neceſſary; as the fineſt emery, that waſhes off in grinding, may be again uſed to give a ſmooth ſurface before poliſhing, as the Tulleys, father and ſon, have ſometimes done, perhaps more out of curioſity than choice, and have thus begun and finiſhed the proceſs with only *one tool*, unleſs the ſpeculum itſelf be called a tool for equalizing the pitch. Lord Stanhope, and his operator, Mr. Varley, who are engaged in making experiments in poliſhing ſpecula, have uſed Welſh ſlate with ſucceſs for compoſing a bed of poliſhing materials; and no doubt there are various ſtones not tried that may hereafter prove ſuperior to thoſe hitherto uſed for this purpoſe. The braſs and ſilver recommended by Edwards are, moreover, now generally omitted by the beſt opticians, as tending to diminiſh the hardneſs of the metal more than is requiſite; but the arſenic is ſtill retained. And, laſtly, the property of the *elliptic* tool, aſcribed to it by Edwards, is diſallowed by ſeveral of the moſt ſkilful opticians; ſo that, after all, each workman ſucceeds beſt when he practiſes the methods of grinding, poliſhing, and giving the requiſite figure, in which his own ſkill and experience have rendered him moſt expert, and conſequently moſt confident.

Speculum, *Horizontal.* See Horizontal.

Speculum. This name is given to ſeveral inſtruments employed in *Surgery*, for gaining a view of tumours, or ulcers, ſituated within cavities. Thus, there are ſpecula ani, ſpecula auris, &c. The ſpeculum oculi is an inſtrument for opening the eye-lids, and keeping them apart, ſo that the ſurgeon may have a good view of the eye.

Speculum *Muſicæ*, the title of a muſical treatiſe, written in Latin by John de Muris, (ſee Muris,) and only to be found among the MSS. in the late king of France's library, at Paris. It is a treatiſe ſo ample, and ſo ſcarce, that, having procured large extracts from it, and a complete table of its contents, we ſhall be the more minute in our account of it, as it ſeems to have been the ground-work of all the muſical treatiſes that were produced by other writers, till the time of Franchinus Gaforius, in the latter end of the 15th century.

This work, which is written on vellum, in folio, contains ſix hundred pages. The firſt ſentence of the original is, "Libro tertio de Philoſophica Conſolatione Boetius volens reddere Cauſam," &c. It is divided into ſeven books: the firſt of which treats of the invention of muſic, and of its diviſions, and contains 76 chapters; the ſecond, of muſical intervals, 123; the third, of harmonics, or muſical proportion, 56; the fourth, of concords and diſcords, 51; fifth, of the ancient tetrachords, diviſion of the monochord, and doctrines of Boethius, 52 chapters; ſixth, of the modes and notation of the ancients, of the changes made in their ſyſtem by Guido, and of the eccleſiaſtical tones, 113. Book the 7th, of meaſured muſic; of diſcant, in treating of which he has the chapter "de ineptis Diſcantoribus," part of which has been given in the preceding chapter; of the time-table, moods or diviſions of time; of the folly of placing a tail to the ſemibreve, by which he ſeems to mean the minim, without naming it; of perfect and imperfect meaſures; and laſtly, a parallel between ancient and modern muſic, which occupies the laſt five of the 45 chapters into which this book is divided, the concluding ſentence of which is, "Exempli cauſa deſcribere tibi volo quorum figuræ ſunt in hoc ordine conſequentes.

Explicit Tractatus Muſicæ, Magiſtri
Johannis de Muris."

Notwithſtanding all the nice and ſubtle diviſions and ſubdiviſions of his ſeven books into 917 chapters, the practical muſician would at preſent profit but little from the ſtudy of them, as almoſt all the doctrines contained in the firſt five books are ſpeculative, and ſuch as may be found in Ptolemy, Boethius, and other ancient authors, whom almoſt all the muſical writers of later times have copied in pure pedantry, without underſtanding themſelves what they read, and conſequently without conveying any uſeful ſcience to their readers by what they have written. It is only in the two laſt books that De Muris condeſcends to ſpeak of the practical muſic of his own times: in the ſixth book he treats of the eccleſiaſtical tones, notation, and chants, which John Cotton and Walter Odington had done before; and in the ſeventh he defines cantus menſurabilis, diſcant, moods, characters of the different duration of ſounds, as the long, breve, ſemi-breve, and their perfection and imperfection. Here he employs ſeveral chapters in refuting ſuch as have diſputed his doctrines; and laſtly, he draws a parallel between the muſic of the ancients and that of the moderns, in order to aſcertain their ſeveral degrees of perfection.

It is in mere charity to the curious in muſical antiquities that we have beſtowed ſo much pains in examining and deſcribing this book; which, though of difficult acceſs, and more difficult peruſal, might tempt them, from the celebrity of the author, to explore its dark regions, and impair their eyes and patience in ſearch of ſcientific treaſures which it does not contain.

SPECULUM *Veneris*, in *Botany*, a name borrowed from the Flemings, given by Gerarde to an annual ſpecies of *Campanula*, common in gardens, and remarkable for the brilliancy of its deep blue flowers with a white centre. Linnæus has retained this as a ſpecific name, and the plant is commonly called Venus's Looking-glaſs. See CAMPANULA and PENTAGONIA.

SPEEAN, in *Rural Economy*, provincially uſed to ſignify to wean from the dams, as calves, hogs, lambs, and other animals.

SPEEAVE, provincially to ſay or cut young animals.

SPEECH, the act, or art of expreſſing a man's thoughts, by certain ſigns invented for that purpoſe.

Theſe ſigns are principally ſounds made by the voice, and letters. See LANGUAGE.

SPEECH, in *Grammar*, denotes an aſſemblage of ſeveral words ranged in order.

The grammarians generally make eight parts of ſpeech, *i. e.* eight kinds of words uſed in diſcourſe; *viz. noun, pronoun, verb, participle, adverb, conjunction, prepoſition*, and *interjection*; each of which ſee under its proper article.

F. Buffier, one of the laſt writers on grammar, only admits of three parts of ſpeech, *viz. noun, verb*, and *modificative*; which laſt includes the *adverb, conjunction*, and *prepoſition*.

The ingenious Mr. Harris, after Ariſtotle, diſtributes all words into four ſpecies, *viz.* ſubſtantives, or nouns; attributives, or verbs; definitives, or articles; and connectives, or conjunctions; the two former are principals, or ſignificant from themſelves; and the two latter are acceſſories, or ſignificant by relation. Under theſe four ſpecies are included pronouns, adverbs, prepoſitions, and interjections. Hermes, p. 31.

SPEED, JOHN, in *Biography*, a conſiderable elucidator of the geography and hiſtory of Great Britain, was born in 1552, at Farrington, in Cheſhire. He was brought up to the trade of a tailor, and was, by apprenticeſhip, a freeman of the company of Merchant Tailors in London, when that patron of learning, ſir Fulk Greville, diſcovering his attachment to the antiquities of his country, gave him an allowance to enable him to quit his employment, and devote himſelf to ſtudy. His firſt publication was entitled "The Theatre of the Empire of Great Britain, preſenting an exact Geography of the Kingdoms of England, Scotland, and Ireland, and the adjacent Iſles." This work conſiſted of a ſet of maps of all the counties, with the ichnography of the principal towns, and brief deſcriptions, moſtly copied from Camden's Britannia. His greateſt work, the labour of fourteen years, entitled "The Hiſtory of Great Britain," appeared in the year 1614. It is chiefly a compilation from preceding authors and manuſcript records, compriſing all the events in Britiſh hiſtory, from the invaſion of Julius Cæſar to the reign of king James I.; and though rude in ſtyle, yet it contained more valuable matter, and is better arranged, than the preceding chronicles. Speed, it is ſaid, was the firſt Engliſh writer who, ſlighting Geoffrey's tales, fell upon more ſolid matter. He was aſſiſted by ſir Robert Cotton, who reviſed and corrected the whole. Mr. Speed was author of a work entitled "A Cloud of Witneſſes, or Genealogies of Scripture," prefixed to the new tranſlation of the Bible in 1611, and to ſeveral ſubſequent editions of it. This uſeful and induſtrious man paſſed 57 years in the marriage ſtate, with a wife, by whom he had twelve ſons and ſix daughters. He died at London in 1629, and was buried in the church of St. Giles, Cripplegate.

SPEEDWELL, in *Botany*. See VERONICA.

SPEEDWELL, *Female*. See ELATINE.

SPEEDY-CUT, a term uſed to ſignify a kind of cut which happens to a horſe when put to his ſpeed. See SHOEING *of Horſes*.

SPEEN, or *Speenham Land*, in *Geography*. See NEWBURY.

SPEGEL, HAQUIN, in *Biography*, a Swediſh archbiſhop, diſtinguiſhed for great learning, was born in 1645. After acquiring the rudiments of a good education, he was ſent to the academy of Greipſwald; made a tour to Germany, Holland, England, Denmark; and on his return took his degree of maſter of arts at Lund, in 1671. The ſame year he was appointed chaplain to Charles XI., whom he accompanied in his campaigns during the whole Dutch war. In 1685 he was made biſhop of Skara, was tranſlated thence to Linköping in 1691, and in 1711 was raiſed to the archiepiſcopal chair. After the fire which took place at Linköping in 1700, he contributed by his active exertions towards rebuilding the Gymnaſium, a ſervice of ſo much importance, that the remembrance of it is ſtill preſerved by an inſcription on the front of the building. He augmented the library with a great number of excellent books, and on the death of his ſon, preſented to it a collection of medals and coins. He died at Upſal, in 1714. Among his works, which were numerous, are the following: "A Hiſtory of the Swediſh Church; or a Chronicle of the Biſhops, in two Parts;" "Sermons on Chriſt's Sufferings;" "Gloſſarium Linguæ Gothicæ;" beſides a great number of hymns, and various ſermons.

SPEIGHT's Town, in *Geography*, a ſea-port of the iſland of Barbadoes, ſituated on the weſt coaſt, near the northern part of the iſland, formerly much frequented by the Briſtol traders, and thence called Little Briſtol. It is a handſome town, containing about 350 well-built houſes, diſpoſed into four regular and ſpacious ſtreets, of which the longeſt is called Jews'-ſtreet, and, with the other three, leads down to the water ſide. The planters in that part of Barbadoes called Scotland, uſed to ſhip off their goods here for England, which occaſioned the building of ſtore-houſes, and a concourſe of people, to the great advantage of the town; but moſt of the trade is now removed to Bridge-town. It has a ſpacious church, dedicated to St. Peter, which gave name to its precinct, and is the place where the monthly ſeſſions are held. The town is defended by two forts, beſides another in Heathcote's bay, ſome diſtance ſouth of the town. One of the above forts ſtands in the middle of the town, and is mounted with 14 guns; the other, which hath 32, ſtands at the north end of it: but there are, beſides theſe, ſeveral platforms on the ſea-ſhore. N. lat. 13° 15'. E. long. 58° 31'. Edwards's Weſt Indies.

SPEISSE, in *Mineralogy*, a name given by the Germans, and other workers on cobalt, to a ſort of impure regulus of biſmuth, ſometimes occurring in their proceſſes.

It is not uncommon for ores of biſmuth to be mixed with the cobalt in the ſmalt-works. Both this ore and the cobalt yield the blue vitrifiable earth of which ſmalt is made; but in one of them it is blended with arſenic, and in the other with the biſmuth. The ſeparation of it from theſe two minerals requires different proceſſes, and the workmen, therefore, ſeparate the two minerals, and work each by itſelf; but it ſometimes happens that the ore of biſmuth is ſo like to the true cobalt, that it cannot be diſtinguiſhed by the eye, and ſo intimately mixed with it, that it cannot be ſeparated from it; in this caſe the whole is expoſed to the fire together, and after the arſenic is ſublimed in form of meal, there remains a coarſe and impure regulus of biſmuth, which having mixed itſelf with the earth of the cobalt, and other extraneous ſubſtances, is of a reddiſh-white colour, and very impure and friable. This gives them the trouble of a ſecond operation, by which they ſeparate the pure regulus of biſmuth, and the remainder being a mixture of its earth and that of the cobalt, is run together into the blue glaſs called *ſmalt*, the earth of biſmuth ore being of the ſame nature with that of cobalt. Phil. Tranſ. N° 396, p. 199.

SPEL, in *Rural Economy*, a term provincially uſed to ſignify a bar. It alſo ſignifies the thin ſtraight or bent ribs in the work of baſket or ſieve-making in ſome places.

SPELE, in *Geography*, a town of the iſland of Candy; 15 miles S.E. of Candy.

SPELK, in *Rural Economy*, a ſmall thin rod, or piece of wood uſed in thatching. Small hazel rods are moſtly employed in this way.

SPELL, a kind of charm, to drive away a diſeaſe, by hanging a word or ſentence written on a paper about the neck. See Charm.

Spell, in *Sea Language*, the period in which a ſailor, or gang of ſailors, is employed in a particular exerciſe, from which they are relieved as ſoon as the limited time expires. Such are the ſpells to the hand-lead in ſounding, to the pump, to look out on the maſt-head, &c. and to ſteer the ſhip, which laſt is generally called the *trick*.

Spell alſo implies the relief or return of duty to thoſe ſervices: thus it is ſaid, ſpell the pump, ſpell the lead, &c.

SPELLING, that part of grammar properly called orthography.

Dr. Jones gives the following rules, or maxims, of ſpelling.

1. That all words were originally pronounced as ſpelt.

2. That in all words whoſe ſounds have been ſince altered (the origin of the difficulty of ſpelling), the alteration was made for the ſake of eaſe and pleaſure.

And hence, 3. All words that can be written ſeveral ways, muſt be ſpelt according to the hardeſt, harſheſt, and moſt unuſual ſound.

SPELLO, in *Geography*, a town of the Popedom, in the duchy of Spoleto. This was anciently Hiſpellum, and being made a Roman colony by Julius Cæſar, was by him named Colonia Julia Hiſpella. In the year 1529, it was ſacked by Philibert de Châlons, prince of Orange, general of Charles V.; and three years afterwards the walls were ordered to be pulled down by pope Paul III.; 10 miles S.W. of Nocera.

SPELMAN, *Sir* Henry, in *Biography*, an eminent antiquary, was deſcended from an ancient family ſettled in Norfolk. He was born in 1562, at Congham, near Lynn, and having received a common education, he was ſent at an early age to Trinity college, Cambridge. Owing to his father's death, he was called from the univerſity before he had completed his 17th year, and he was afterwards entered of Lincoln's-Inn, in order that he might ſtudy the common law, but his inclination was not favourable to legal purſuits: he ſeems to have given a decided preference to polite literature and antiquities, but theſe purſuits were cut ſhort by an early marriage, which induced him to ſettle upon his eſtate, and take the management of it in his own hands. He did not, however, abandon his antiquarian purſuits, and while he was yet a very young man, he drew up a treatiſe in the Latin language, entitled "Aſpilogia," relative to armorial bearings, and made tranſcripts of ſeveral charters of monaſteries in Norfolk and Suffolk. He was alſo aſſociated to the original ſociety of antiquarians, and became the intimate friend of Cotton, Camden, and other favourers of that claſs of ſtudies. In 1604 he was elected high ſheriff of the country, and about the ſame time communicated to Speed a deſcription of Norfolk, for his work entitled "The Theatre of Great Britain." In 1607 he was nominated by the king one of the commiſſioners for ſettling the titles to lands and manors in certain counties of Ireland, and on this occaſion he went thrice to that country. Farming now became irkſome, becauſe he probably found it unprofitable: he ſold off his ſtock, let his eſtates, and came with his family to London, and he choſe as the particular object of his ſtudies, the antiquities of Engliſh law, as deducible from Engliſh records; but he was diverted from his object by an incidental ſubject. During his reſidence on his eſtate, he had purchaſed the lands of two ſuppreſſed monaſteries, and being involved in a troubleſome law-ſuit in order to defend his title, he began to entertain ſcruples concerning the ſecularization of property once belonging to the church. When, therefore, an uncle of his complained to him of difficulties which he had met with in building upon the glebe of an impropriate parſonage, he plainly gave his opinion, that it was a token of divine diſpleaſure for keeping the parſonage in lay hands, and he drew up a work in 1613, with the title "De non temerandis Eccleſiis; Churches not to be violated; a Tract of the Rights and Reſpects due to Churches, &c." He practiſed what he had pleaded for in theory, and being poſſeſſed of an impropriation in Norfolk, he devoted the profits of it to the augmentation of the vicarage.

By king James he was knighted, and on the revival of the ſociety of antiquarians in 1614, he attended as one of the old members; on which occaſion he wrote "A Diſcourſe concerning the Original of the four Law Terms of the Year." His zeal for the honour of the church and the authority of the canons, induced him to write a tract in anſwer to an apology for archbiſhop Abbot, who had accidentally killed his game-keeper, in which he maintained that the prelate by that act had ceaſed from his office, and could not be reinſtated without a new conſecration. Having in the mean time continued his enquiries into legal antiquities, he found that the knowledge of the Saxon language was abſolutely neceſſary to his purpoſe, which he accordingly ſet about obtaining, and in 1621 he printed a ſpecimen of his propoſed work, which was ſo much approved, that ſeveral eminent ſcholars urged him to its completion. In 1626 he publiſhed the firſt part, under the title of "Archeologus, in modum Gloſſarii ad rem antiquam poſteriorem." Notwithſtanding the applauſe of the learned, the author was not encouraged by the ſale of his work to publiſh the ſecond part during his life, which he had fully prepared for the preſs. It was, however, given to the world after his deceaſe, and the whole was entitled "Gloſſarium Archaiologicorum." The object of this work is the explanation of obſolete words occurring in our laws; and it is not a mere gloſſary, but contains various entire diſſertations. He next employed himſelf in a collection of Engliſh laws and ſtatutes, from the Conqueſt to the ninth year of Henry III., which was printed in 1617. Having been appointed, on the recommendation of archbiſhop Laud, one of the commiſſioners for enquiring into the exaction of fees in the courts and offices throughout England, he publiſhed, in 1628, a tract "De Sepultura," or concerning "Burial Fees." Before our author had finiſhed his gloſſary, he engaged in another conſiderable work, which was "A Hiſtory of the Engliſh Councils." Of this he publiſhed in 1639 the firſt part, which included the period from the firſt introduction of the Chriſtian religion into England to the Norman Conqueſt. A ſecond part, only a ſmall portion of which was of his own compoſition, was printed ſeveral years after his death. In the ſame year he inſtituted a Saxon lecture in the univerſity of Cambridge, which he intended to have rendered perpetual, but his deſign was defeated. In 1639 alſo he publiſhed a treatiſe on "The original Growth, Propagation, and Condition of Tenures by Knights' Service in England," in which he diſplayed an extent of learning that proved his faculties to be perfect, notwithſtanding his advanced age. He lived to complete his 80th year, and died at London in 1641. By the king's order, he was interred in Weſtminſter Abbey. After his deceaſe, two poſthumous works of his were publiſhed, *viz.* "A Treatiſe concerning Tythes," printed in 1647; and "A Hiſtory of Sacrilege," which was deſtroyed at the printer's by the great fire of London, and a plan of it only preſerved. In 1698 biſhop Gibſon publiſhed a folio volume, entitled "Reliquiæ Spelmanniæ," containing a number of his poſthumous tracts relative to the Engliſh laws and antiquities. He was, ſays his biographer, a very reſpectable promoter of antiquarian learning, and a man of great private worth.

SPELMAN, EDWARD, great-grandſon of the preceding, reſided at High-Houſe, near Rougham, Norfolk, where he died in 1767. He had devoted himſelf to literature, and made himſelf known by ſeveral publications of conſiderable worth. The firſt of theſe was a tranſlation of Xenophon's "Cyropedia," in two volumes, 8vo. A more elaborate work was entitled "The Roman Antiquities of Dionyſius Halicarnaſſenſis," tranſlated into Engliſh, with notes and diſſertations, in four volumes, quarto, a work which ſtands high among our tranſlations from the Greek language. One of theſe diſſertations was a verſion of a fragment of Polybius on government, particularly that of Rome, to which the tranſlator prefixed a preface, applying the ſyſtem of Polybius to the Engliſh government. This was printed without his name in 1743. He alſo printed for the uſe of his friends, and for private diſtribution only, "A Diſſertation on the Preſence of the Patricians in the Tributa Comitia:" and after his death the Rev. Mr. Lemon publiſhed in 1775, a poſthumous work of this writer, entitled "Additional Obſervations on the Greek Accents." Gen. Biog.

SPELT, in *Agriculture*, a term applied ſometimes to wheat-graſs, a ſpecies of *triticum*, or wheat. It is ſometimes written *ſpelta*.

SPELTA, in the *Materia Medica*, a name uſed for the grain of the zea dicoccos, commonly called *ſpelt-corn*.

SPELTER, or **SPELTRE**, a name ſometimes given to zinc.

SPELUNCATO, in *Geography*, a town of the iſland of Corſica; 12 miles E. of Corte.

SPENAZZOLA, a town of Naples, in Baſilicata; 13 miles E. of Venoſa.

SPENCE, JOSEPH, in *Biography*, was educated at New college, Oxford, of which he afterwards became a fellow. He took the degree of M.A. in 1727, and in that ſame year made himſelf known by "An Eſſay on Pope's Tranſlation of the Odyſſey." This work diſplayed a cultivated taſte, as well as a ſenſibility to the beauties of poetry, and was ſo favourable to the tranſlator, that he ſought his acquaintance, and admitted him to a familiar intimacy. In the following year he was elected profeſſor of poetry of the univerſity of Oxford, an office which he held for ten years. After this he travelled with the young duke of Newcaſtle, and in 1742, having quitted his fellowſhip, he was preſented by his college to a rectory in Buckinghamſhire. He reſided, however, at Byfleet, in Surrey, at a manſion lent him by the duke his pupil, and thus performed the duties of rector merely by an annual viſit, attended with liberal charities. In the ſame year he was elected king's profeſſor of modern hiſtory, at Oxford: this was a duty as eaſy to be performed as the other, but he did not devote that leiſure which his preferments offered him to indolence, for in 1747, he brought to the preſs his principal work, entitled "Polymetis, or an Enquiry concerning the Agreement between the Works of the Roman Poets and the Remains of ancient Artiſts, being an Attempt to illuſtrate them mutually by each other." This was a folio work, with plates. The performance was extremely well received by the public, and ſtill ſtands very high in the literary world, though it has been ſlighted by ſome few, who perhaps haſtily condemned, before they had given proper attention to it. In 1754 he was preſented with a prebendary of Durham, and he continued to amuſe himſelf with a variety of miſcellaneous compoſitions that appeared in different forms. His laſt publication was an edition of "Holdſworth's Remarks on Virgil," with notes, and additional obſervations of his own. In the month of Auguſt, 1758, he was found drowned in a piece of water in his own garden at Byfleet, into which it is ſuppoſed he had fallen in a fit, the water being too ſhallow to cover him. He is characteriſed as being of a ſocial benevolent diſpoſition, and being very much beloved by his friends. He was ſtudious to draw obſcure merit into notice, of which he gave evident proofs by his printed account of Stephen Duck; Robert Hill, the learned tailor;

and Mr. Blacklock, the blind poet. Several of his detached and miſcellaneous compoſitions were inſerted in the “Muſæum,” and in Dodſley's “Fugitive Pieces.” He had collected ſome MS. volumes of anecdotes of eminent writers, communicated by Pope and others, which are ſtill in the poſſeſſion of the duke of Newcaſtle's family, and from which Dr. Johnſon was permitted to make extracts for his lives of the poets. Gen. Biog.

SPENCER, John, a learned divine of the church of England, was born in 1630, at Bocton-under-Bleane, in Kent. His father dying while he was an infant, the care of educating him was undertaken by an uncle, who ſent him to the free-ſchool of Canterbury. His proficiency in learning procured for him a recommendation to a ſcholarſhip in Caius college, Cambridge, where he was admitted in 1645. Paſſing through the uſual gradations in that univerſity, he was choſen fellow of his college in 1655, and took orders: of courſe he muſt have complied with the requiſitions of the ruling powers at that time. He became diſtinguiſhed for his pulpit compoſitions, and was appointed univerſity preacher, in which capacity he took an opportunity of hailing the event of the Reſtoration by a thanſgiving ſermon, which was printed under the title of the “Righteous Ruler,” which, in reference to the profligate character of the reſtored ſovereign, muſt have been regarded as extremely appropriate! Some enthuſiaſts having, in a periodical paper entitled “Annus Mirabilis,” brought to notice a number of pretended prodigies, as portending future changes in the ſtate, Spencer conceiving it to be of dangerous conſequence thus to unſettle the minds of the people, publiſhed in 1663, “A Diſcourſe concerning Prodigies,” wherein a variety of preſages by them is reprehended, and their true and proper uſe is aſſerted and vindicated. A ſhort extract from the preface will ſhew the nature of the work: “We have,” ſays he, “of late been perſuaded by three or four ſeveral impreſſions of books, that England is grown Africa, and preſents us every year, ſince the return of his majeſty, with a new ſcene of monſtrous and ſtrange ſights; and all held forth to the people, like black clouds behind a ſtorm, the harbingers of ſome ſtrange and unuſual plagues approaching to the ſtate; and this by perſons pretending an intimacy with ſcripture, and the fathers, Greek and Latin, ancient and modern writers.” The work diſplayed a freedom from credulity and ſuperſtition very laudable at that time. To a ſecond edition, in 1665, was added “A Diſcourſe concerning vulgar Prophecies;” in which the vanity of receiving them as the certain indications of any future event is diſcovered, and ſome characters of diſtinction between true and pretended prophets are laid down. This attempt to bring down the public to reaſon and ſobriety was not leſs timely than the former, and might have been uſefully renewed in many other inſtances and at much later periods. The author in the ſame year proceeded doctor in divinity. He was, in 1667, preſented to a living by his college, and in a very ſhort time after was elected to the maſterſhip of that ſociety, an office which he held with high reputation during twenty-ſix years. Several preferments were beſtowed upon him, of which the laſt and moſt conſiderable was the deanery of Ely in 1667. He had previouſly been choſen vice-chancellor of the univerſity of Cambridge, and in that quality he made a ſpeech to the duke of Monmouth, when he was inſtalled chancellor, which was printed by Hearne, in his work entitled “Vindiciæ Thom. Caii.” It was particularly as a maſter of Hebrew literature and antiquities he is known in the learned world. His firſt work was written in the Latin language, a diſſertation “De Urim et Thummim,” which was publiſhed in the year 1678. This was a forerunner of his great work, “De Legibus Hebræorum Ritualibus, et earum Rationibus, Libri Tres,” 2 vols. fol. 1685; a performance conſidered ſo valuable and important, that it was reprinted at the Hague in 1686, and at Leipſic in 1705. The grand object of this work is to prove, in detail, that the rites and ceremonies of the Jewiſh religion were inſtituted in direct oppoſition to the practices of the ſurrounding idolatrous nations, and in order to eſtabliſh the ſtrongeſt diſtinction between the Jews and them. The ſame hypotheſis has been maintained by ſeveral learned men, and has been oppoſed by others, without affecting on either ſide the authority of that religion. Spencer's work is ſtill conſidered as the moſt complete and judicious treatiſe in that view of the queſtion. The author died at the age of ſixty-three, and he was interred with great ſolemnity in the chapel of his college, to which ſociety he was a liberal benefactor. He left behind him many MS. additions to his great work; which were entruſted to the care of biſhop Tenniſon, by whom they were bequeathed to the univerſity of Cambridge, and were eventually publiſhed in four books, under the care of profeſſor Capellow, in two vols. folio. Biog. Brit.

Spencer, in *Geography*, a townſhip of America, in Worceſter county, Maſſachuſetts, taken from Leiceſter, and incorporated in 1733, containing 1453 inhabitants; 11 miles S.W. of Worceſter.

Spencer, a large poſt-townſhip of New York, the capital of Tioga county, is ſituated near the centre of that county, 50 miles S.E. of Bath; bounded N. by Cayuta and Danby, E. by Candor, S. by Oſwego, and W. by Chemung. Spencer was divided in 1811; and Cayuta, Danby, Caroline, and Candor, erected into ſeparate towns from the N. and E. parts. The population of Spencer in 1810 was 3128. It is well ſupplied with ſmall creeks and mill-ſtreams. The Catetant winds acroſs the northern part with numerous branches; the Cayuta forms the weſtern boundary; and ſome ſmaller ſtreams ſpread over the central part. The ſoil is of various qualities, and the ſurface has a conſiderable hilly aſpect, covered with a great variety of foreſt-trees. The ſeat of juſtice for the county has been lately removed from Elmira to this townſhip, and the county buildings are within Drake's ſettlement, as it is called, ſituated on the Catetant creek; where is a ſmall village, denominated Spencer; and as its ſituation is pleaſant and healthy, and it is the centre of county buſineſs, it promiſes to become a flouriſhing county village.

SPENSER, Edmund, in *Biography*, one of the moſt diſtinguiſhed Engliſh poets, was born in London about the year 1553. His parents were in humble life, though in his works he claims kindred with the noble family of the Spenſers of Northamptonſhire. Of his early education nothing is known, but it appears that he was, in 1569, a ſizer in Pembroke college, Cambridge. He, in proper time, took his degrees, and in 1576 he was candidate for a fellowſhip, but was not ſucceſsful. This diſappointment was probably the cauſe of his quitting the univerſity, which he left for a reſidence among his relations in the north of England. Here, it appears, he fell in love, and the object of his affection, whom he has commemorated under the name of Roſalindo, after leading him through the uſual viciſſitudes of a love adventure, finally deſerted him. This circumſtance is ſaid to have given him a turn to paſtoral poetry, ſince his “Shepherd's Complaint,” which is devoted to amorous complaining, was his firſt publication. It was publiſhed in 1579, and dedicated, under the ſignature of Immerito, to Mr. afterwards ſir Philip Sidney. He was introduced to the acquaintance of this celebrated perſon by his friend, Mr. Gabriel Harvey, previouſly to his publiſhing his "Shepherd's Calendar," which ſufficiently refutes a tale concerning his being firſt made known to ſir Philip Sidney by a paſſage in the Faery Queen, and the munificent reward which he received on the occaſion. He was, however, patronized by ſir Philip, who introduced him to his uncle, the favourite Leiceſter, who engaged him as an agent for his ſervice in foreign countries, but it is uncertain whether he ever actually travelled abroad; at any rate he could not have been long in that employ, ſince, in 1580, he was attending lord Grey of Wilton, appointed lord-deputy of Ireland, as his ſecretary. In this ſituation he diſplayed thoſe talents for buſineſs, which are uſually, though often very unjuſtly, repreſented as incompatible with a poetic genius. He returned with lord Grey in 1582, and was probably ſome years an attendant at court, and in 1586 he had a grant from the crown of upwards of 3000 acres of land in the county of Cork, out of the vaſt forfeited property of the earl of Deſmond. In 1587 Spenſer went over to take poſſeſſion of this eſtate; his reſidence was the caſtle of Kilcolman, near Doneraile, where, in the ſtyle of paſtoral poetry, he deſcribes himſelf as keeping his ſheep "under the Mole, that mountain hore," and frequenting the coolly ſhade of the green alders by the Mulla's ſhore. Here it appears he received a viſit in 1589 from ſir Walter Raleigh, who had been a commander in Ireland under lord Grey, and had obtained a large grant of land from the crown. Spenſer celebrates him in a poem under the title of the "Shepherd of the Ocean," and highly extols his courteſy and elegant accompliſhments. At this period Spenſer was engaged in the compoſition of his "Faery Queen," of which he had written the three firſt books; and accompanying Raleigh the next year to England they were publiſhed, with a dedication to queen Elizabeth, and an introductory letter addreſſed to Raleigh, explaining the plan of the whole projected work. Elizabeth rewarded his poetry and dedication by a penſion of 50*l. per annum*, granted in 1591, and he has been termed her laureat, though the title was not formally conferred upon him. Spenſer returned to Ireland in 1591, and married a country laſs of low degree, but the diſturbances in that country forced him to return to England in 1595. Here he printed ſome poems, and drew up a plan for the entire reduction of that iſland in the ſpace of two winters, which work he completed in the next year, giving it the title of "A View of the State of Ireland." This piece remained in MS. till it was printed in 1633 by ſir James Ware, who beſtows much applauſe on the information and judgment diſplayed in it, though he intimates, that it was deficient in moderation: and it is generally admitted, that in what he ſays concerning the hiſtory and antiquities of the country there are many errors, and the fanciful turn of a poet is more conſpicuous than the ſobriety of a judicious enquirer. In 1596 he publiſhed a new edition of his "Faery Queen," with additional books, which only completed half his original deſign. It was currently reported, that the remaining ſix books were loſt by a ſervant, who was entruſted to carry them to England, which certainly would be one of the greateſt diſaſters that a poet could poſſibly ſuffer, and might greatly contribute to break his ſpirits: the fact, however, is very queſtionable, and certainly does not ſtand on good authority; it is moſt probable that they were never finiſhed. He returned to Kilcolman in 1597, but Tyrone having in the next year broken out in rebellion, and overrun the county of Cork, Spenſer was obliged to take refuge with his wife in England, leaving all his property to the ſpoil and ravages of the inſurgents. His houſe was burnt, and with it, it is ſaid, an infant who had not been removed. Reduced to a ſtate of indigence, he ſunk under his misfortunes in the ſame year, or in the beginning of the next. He was interred in Weſtminſter Abbey, at the expence of the earl of Eſſex, ſeveral of his brother poets attending, and throwing into his grave copies of panegyrical verſes. A monument was afterwards erected to his memory by Anne, the celebrated counteſs of Dorſet. Of his family and poſterity nothing is known, except that one of his deſcendants was reſtored in the reign of Charles II. to ſo much of the eſtate in Ireland, as he could prove had belonged to his anceſtor; and that another, or perhaps the ſame, came to England in the reign of William with a ſimilar claim, which was allowed. The works of Spenſer are animated with a fervent ſpirit of piety, and a pure and exalted morality; and though he certainly paid an aſſiduous court to the great, he was not guilty of that meanneſs of adulation, which was too much practiſed even by ſome eminent perſons of that age. The homage paid to the queen was great, but it was deemed impoſſible to carry this too far.

The poetical reputation of Spenſer is chiefly ſupported by his great work the "Faery Queen," for his paſtorals will ſcarcely pleaſe a correct taſte; and though critics admit that there is much occaſional beauty of ſentiment and harmony of verſification in his ſonnets, hymns, and other miſcellaneous pieces, yet on the whole they are ſcarcely diſtinguiſhed from the effuſions of tedious pedantry common in that age. But the "Faery Queen" is juſtly regarded as one of the great compoſitions in Engliſh poetry, and has loſt none of its value by antiquity. "If its plan is ſingularly involved, its allegories often defective and obſcure, and its adventures extravagant, it is, however, abſolutely unrivalled for the fertility of its conceptions, and the vividneſs of its painting. Its great length, and want of intereſt as a fable, deter readers, in general, from a complete peruſal, but it will always be reſorted to by the lovers of poetry as a rich ſtorehouſe of invention, eſpecially of that kind which conſiſts in the perſonification of moral ideas." Biog. Brit.

SPENT, at *Sea*. The ſeamen ſay a ſhip hath ſpent any maſt or yard, when it is broken down by foul weather, or any ſuch accident; but if it be done by an enemy's ſhot in a fight, they ſay, *ſuch a yard*, or *maſt*, *was ſhot by the board*.

SPERA, in *Geography*, a town of European Turkey, in Dobruzzi Tartary; 40 miles S. of Iſmail.

SPERAGE, Asparagus, in *Botany*. See Asparagus.

SPERDILLEN, in *Geography*, a lake of Norway, in Aggerhuus, 32 miles long and 12 wide; 4 miles N. of Chriſtiania.

SPERGULA, in *Botany*, a word which Dodonæus, who is cited as its author, expreſsly ſays was latinized from the name of this herb in Brabant, *Spuerie*, whence its Engliſh appellation, Spurrey. Whether σπυρὶ, a modern Greek name for *Verbaſcum Blattaria*, has any common origin with this Flanders word, or whether both may allude to the copious diſperſion of ſeeds in both caſes, and have been derived from the ancient Greek *σπειρω*, *to ſow*, or *ſcatter*, we can only propoſe as a conjecture. Linnæus, however, ſeems to have had ſome ſuch etymology in contemplation, when he, in Phil. Bot. p. 167, explains *Spergula* by "*a ſcattering of ſeed*;" though probably he looked no further than the Latin, *ſpargo*.—Linn. Gen. 232. Schreb. 312. Willd. Sp. Pl. v. 2. 818. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 502. Prodr. Fl. Græc. Sibth. v. 1. 317. Ait. Hort. Kew. v. 3. 137. Purſh v. 1. 320. Dill. Gen. 131. t. 7. f. 3.

Juſſ. 301. Lamarck Illuſtr. t. 392. Gærtn. t. 130.—Claſs and order, *Decandria Pentagynia*. Nat. Ord. *Caryophyllei*, Linn. *Caryophylleæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of five ovate, obtuſe, concave, ſpreading, permanent leaves. *Cor.* Petals five, ovate, concave, ſpreading, undivided, larger than the calyx. *Stam.* Filaments ten, rarely but five, awl-ſhaped, ſhorter than the corolla; anthers roundiſh. *Piſt.* Germen ſuperior, ovate; ſtyles five, ſomewhat reflexed, thread-ſhaped; ſtigmas thickiſh. *Peric.* Capſule ovate, covered partly by the calyx, of one cell, and five valves. *Seeds* numerous, globoſe, but depreſſed, ſurrounded with more or leſs of a notched or dilated border.

Eſſ. Ch. Calyx of five leaves. Petals five, undivided. Capſule ſuperior, ovate, of one cell, with five valves.

Obſ. Linnæus remarks, that this genus differs from *Ceraſtium* in having undivided petals. Their general habit alſo differs more than is the caſe with moſt genera of this natural order, that of *Spergula* nearly according with various *Arenariæ*, from which the five ſtyles only diſtinguiſh it. *S. pentandra* has but five ſtamens.

1. S. *arvenſis*. Rough-ſeeded Corn Spurrey. Linn. Sp. Pl. 630. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1535. Curt. Lond. faſc. 5. t. 31. (Sagina ſpergula; Ger. Em. 1125.)—Leaves whorled. Stalks of the fruit reflexed. Seeds kidney-ſhaped, angular, rough.—Native of corn-fields and waſte ground, on a ſandy ſoil, throughout Europe, flowering from July to September. *Root* annual, ſmall. *Herb* more or leſs downy and viſcid, very various in luxuriance, ſomewhat ſucculent and brittle, with a branched, round, looſely ſpreading *ſtem*, whoſe joints are beſet with copious, whorled, linear, obtuſe *leaves*. *Panicles* terminal, forked, divaricated, level-topped. *Flower-ſtalks* downy; ſtrongly reflexed, from the baſe, as the fruit ripens. *Calyx* membranous at the edge, nearly as long as the white *petals*. *Stamens* generally ten; ſometimes five, or ſome intermediate number. *Capſule* almoſt twice as long as the calyx. *Seeds* numerous, kidney-ſhaped or roundiſh, ſwelling, angular, with an obſolete, not dilated nor membranous, border; when ripe they are black, and rough all over with minute tubercles or briſtles. In Flanders, Germany, and the north of Europe, this herb ſerves as fodder, and poultry are fed with its ſeeds. With us it is a troubleſome weed, on a light ſoil.

2. S. *pentandra*. Smooth-ſeeded Corn Spurrey. Linn. Sp. Pl. 630. Willd. n. 2. Engl. Bot. t. 1536. (S. annua, ſemine foliaceo nigro, circulo membranaceo albo cincto; Dill. Giſſ. 46.)—Leaves whorled. Stalks of the fruit reflexed. Stamens five. Seeds lenticular, ſmooth, with a membranous border.—Native of Germany, England, and probably other parts of Europe, in ſandy ground, flowering in July and Auguſt. Mr. Shepherd, curator of the botanic garden at Liverpool, firſt obſerved this plant about that neighbourhood, growing along with the preceding ſpecies, with which it altogether agrees in general appearance, but the *flowers* are perhaps rather ſmaller, and their *ſtamens* are rarely more than five in number. The moſt remarkable difference is found in the *ſeeds*, which are compreſſed and lenticular, always ſmooth, and bordered by a very conſpicuous whitiſh membrane. Such is the difference likewiſe between *Arenaria marina* and *rubra*. We cannot but feel a miſtruſt of this character, however ſtriking, conſidering the cloſe reſemblance between theſe two *Spergulæ*, at leaſt, in other reſpects. The plant found about Liverpool is certainly what Linnæus and Dillenius intended, and therefore the uncertainty expreſſed in *Fl. Brit.* reſpecting *S. pentandra*, is now removed.

3. S. *nodoſa*. Knotted Spurrey. Linn. Sp. Pl. 630. Willd. n. 3. Fl. Brit. n. 3. Engl. Bot. t. 694. Curt. Lond. faſc. 4. t. 34. Fl. Dan. t. 96. (Saxifraga paluſtris alſinefolia; Ger. Em. 567.)—Leaves oppoſite, awl-ſhaped, ſmooth; the upper ones cluſtered. Calyx without ribs.—Native of wet ſandy heaths and commons, in the colder countries of Europe, flowering in July and Auguſt, but not very common with us. Mr. Goodyer, an accurate and ingenious contributor to the ſecond edition of Gerarde's Herbal, firſt detected this ſpecies in England. Its habit is that of an *Arenaria*, eſpecially the pure white *flowers*. The fibrous perennial *root* produces ſeveral ſpreading or proſtrate *ſtems*, three or four inches long, ſlightly branched, beſet with many pairs of awl-ſhaped, ſhort, ſmooth, dark-green *leaves*, accompanied by axillary tufts of ſmaller ones, giving the herb a knotty or jointed aſpect. *Flowers* large, ſtalked, about the extremities of the ſtems. *Styles* five, as well as the valves of the *capſule*, by which alone this plant is ſeparated from *Arenaria*.

4. S. *laricina*. Larch-leaved Spurrey. Linn. Sp. Pl. 631. Willd. n. 4. Sm. Plant. Ic. t. 18. (Alſine n. 61: Gmel. Sib. v. 4. 155.)—Leaves oppoſite, awl-ſhaped, fringed, cluſtered.—A rare ſpecies, found by Steller in Siberia. It differs from the laſt in being ſomewhat larger, with longer, acute *leaves*, fringed at the baſe. Engliſh botaniſts had been accuſtomed to conſider the following as the true *S. laricina*, till the Linnæan herbarium taught them to correct this error.

5. S. *ſaginoides*. Smooth Awl-ſhaped Spurrey. Linn. Sp. Pl. 631. Willd. n. 5. Fl. Brit. n. 4. Engl. Bot. t. 2105. (Alſine n. 64; Gmel. Sib. v. 4. 157.)—Leaves oppoſite, awl-ſhaped, pointleſs, naked. Flower-ſtalks ſolitary, very long, ſmooth.—A rare inhabitant of the Scottiſh highland mountains, flowering in June. Gmelin found it in Siberia. The perennial fibrous *root* reſembles that of *S. nodoſa*, but the herb is ſmaller, more branched and erect, without any axillary cluſters of *leaves*, and having more reſemblance to a *Sagina* than an *Arenaria*. Every part is quite ſmooth, by which, and the want of a briſtly point to the *leaves*, this *Spergula* eſſentially and conſtantly differs from the more common one next deſcribed. The *flowers* are terminal, rather drooping, on long, ſolitary ſtalks. *Petals* white, roundiſh, hardly ſo long as the *calyx*. *Stamens* ten. Profeſſor Swartz deſcribes but five, which makes us doubtful of his plant. *Seeds* kidney-ſhaped, without any edge or border.

6. S. *ſubulata*. Ciliated Awl-ſhaped Spurrey. Swartz in Stockh. Tranſ. for 1789, 45. t. 1. f. 3. Willd. n. 6. Fl. Brit. n. 5. Engl. Bot. t. 1082. (S. laricina; Hudſ. 203. Fl. Dan. t. 858. S. ſaginoides; Curt. Lond. faſc. 4. t. 35. Sagina procumbens β; Linn. Sp. Pl. 185.)—Leaves oppoſite, awl-ſhaped, fringed, tipped with a briſtly point. Flower-ſtalks ſolitary, very long, ſomewhat hairy.—Native of ſandy barren heaths in the north of Europe, flowering with us from June to Auguſt. It is perennial, and reſembles the laſt in general habit, but the *leaves* are conſtantly fringed with glandular hairs, and tipped with a briſtly point. The *flowers* too are ſmaller, with generally hairy glutinous ſtalks, and uſually but five *ſtamens*. *Seeds* ſmall, compreſſed, pale brown, encircled with a black line, but no dilated border.

7. S. *glabra*. Smooth Capillary Spurrey. Willd. n. 7. (S. ſaginoides; Allion. Pedem. v. 2. 118. t. 64. f. 1, excluding the ſynonyms.)—Leaves oppoſite, thread-ſhaped, ſmooth, cluſtered. Flower-ſtalks ſolitary, very long, ſmooth.—Common in the graſſy alpine paſtures of Savoy, according to Allioni, by whoſe work alone we have any knowledge

of this plant. It vies in magnitude with *S. laricina*, but is much more ſlender in the *foliage*, as well as quite ſmooth. *Petals* white, twice as long as the *calyx*. *Stamens* ten.

SPERGULASTRUM, (ſo called from its reſemblance to *Spergula*,) a genus of Michaux, *Flora Boreali-Americana*, v. 1. 275. The author ſpeaks of it as a doubtful genus, differing from *Spergula* chiefly in having but four *ſtigmas*, or rather *ſtyles*, which in one ſpecies vary to three. Perſoon and Purſh have publiſhed this genus under the appellation of *Micropetalum*, the original name being equally contrary to ſenſe and uſage, becauſe it is formed of another eſtabliſhed one, merely varied in termination.

SPERILEN, in *Geography*, a lake of Norway, in Aggerhuus; 35 miles N. of Chriſtiania.

SPERLING, Otto, in *Biography*, ſon of a perſon of the ſame name, was born at Chriſtiania, in Norway, in 1634. He received the early part of his education at Copenhagen; he afterwards ſtudied at the gymnaſium of Bordeſholm, and then at the academy of Helmſtadt. In 1655 he became private tutor to the ſon of M. Wrangel, governor of Swediſh Pomerania, and in 1658 made a tour to Holland, France, and England. In 1662 he went to Hamburgh, as tutor to the youngeſt ſon of Corfits Ulfeld, and in 1674 took the degree of doctor of laws at Kiel. In 1681 he travelled with the ſons of J. A. Von Bachwald, and ſpent ſome time at Paris, where he was employed in arranging the library of the celebrated Colbert, for which ſervice he received a penſion of 200 rix-dollars as long as that noble-minded man lived. On his return he proceeded to Hamburgh, where he practiſed the law: he was afterwards aſſeſſor in the court of Gluckſtadt, and in 1690 he was invited to Copenhagen, where he was employed in various important affairs. In 1692 he was elected profeſſor of juriſprudence and hiſtory, and afterwards of oratory and hiſtory, in the new knights' academy at Copenhagen. In 1698 he obtained leave to reſign, on account of his age, but in 1701 he reſumed his former ſtation as profeſſor of hiſtory and oratory, in which he continued till the ſuppreſſion of the academy in 1710. He became a member of the Royal Society of London in 1700, and died in 1715. He was author of a great many works, among which were the following: "Monumentum Hamburgenſe Benedictinum;" "De Danicæ Linguæ ac Nominis antiqua Gloria et Prærogativa inter Septentrionales," &c. Gen. Biog.

Sperling, in *Geography*, a town of Pruſſia, in the province of Natangen; 15 miles E. of Angerburg.

SPERLINGA, a town of Sicily, in the valley of Demona; 10 miles S. of Miſtretta.

SPERLONGA, a town of Naples, in Lavora; 7 miles S. of Fundi.

SPERM, Sperma, σπερμα, the ſeed of which an animal is formed.

SPERMACETI, or Parmasitty, in *Pharmacy*, is a whitiſh, flaky, unctuous ſubſtance, prepared from oil; principally from that of a cetaceous fiſh, called by ſome the *male whale*, by others *cachalot*, and by the Latins *orga;* diſtinguiſhed from the common whale by its having teeth in lieu of whale-bone, and by a bunch on its back. See Physeter.

The ancients were ſtrangers to the nature of this preparation; and even Schroder ſeems in doubt, whether to reckon it an animal or mineral ſubſtance.

It had its name *ſpermaceti*, ſeed or ſperm of whale, given it, no doubt, to raiſe its value, by a notion of its ſcarcity. The ſpongy oily maſs from which it is made, is found in a large triangular trunk, four or five feet deep, and ten or twelve long, filling almoſt the whole cavity of the head, and ſeeming to be entirely different from the proper brain of the animal. The oil is ſeparated from it by dripping. In this ſtate it has a yellow unctuous appearance, and is brought to England in barrels. An ordinary ſized whale, it is ſaid, will yield upwards of twelve large barrels of crude ſpermaceti. The mode of purifying it in the large way is as follows: the maſs is put into hair or woollen bags, and preſſed between plates of iron in a ſcrew-preſs, until it becomes hard and brittle. It is then broken in pieces, and thrown into boiling water, where it melts, and the impurities, which riſe to the ſurface or ſink to the bottom, are ſkimmed off or ſeparated from it. After being cooled, and ſeparated from the water, it is put into freſh water in a large boiler, and a weak ley of the potaſh of commerce added to it by degrees. This part of the proceſs is thrice repeated, after which the whole is poured into coolers, when the ſpermaceti concretes into a white ſemitranſparent maſs, which, on being cut into ſmall pieces, aſſumes the flaky appearance which it has in the ſhops. Some of our druggiſts, it is ſaid, poſſeſs the art of making it from the ſediment or fæces of any kind of oil.

Some ſophiſticate it with wax; but the deceit is diſcovered, either by the ſmell of the wax, or by the dulneſs of the colour. Some alſo ſell a preparation of oil gained from the tail of the whale, inſtead of that from the brain; which laſt kind turns yellow, as ſoon as opened to the air. In the general, there is no merchandize that ſhould be kept cloſer from the air than ſpermaceti.

Purified ſpermaceti is an almoſt ſilvery white, friable, ſemitranſparent, unctuous ſubſtance, inodorous and inſipid, or having very little flavour, and only a ſlight tallowy odour. It is ſofter and more brittle than white wax; and it is diſtinguiſhed from every other ſpecies of concrete oil, by its ſuperior tranſparency, high luſtre, and cryſtalline texture. Its ſpecific gravity is 9.433, and it melts at 112° Fahr.; and at a higher temperature evaporates, with little alteration. By the aſſiſtance of a wick, it burns with a clear white flame, ſuperior to that of tallow, and without any diſagreeable odour; and this conſtitutes its excellence as a material for candles. By repeated diſtillation, the ſpermaceti becomes permanently fluid at the common temperature. According to the experiments of Crell, its diſtillation requires a greater heat than fat; and the coagulated oil, thus procured, partly white and partly browniſh. By repeated diſtillation it affords a yellowiſh acid, and becomes more fluid, but coagulates in the cold. The acid, rectified by diſtillation, is entirely colourleſs, and affords the ſame ſalts with earths and alkalies as Crell's ſubacic acid. The oil unites with ammonia into a ſaponaceous emulſion. It may be diffuſed in water by means of the yolk of egg or mucilage. It is ſparingly ſoluble in boiling alcohol, 150 parts of the menſtruum being neceſſary for this purpoſe; and as the ſolution cools, the ſpermaceti is again precipitated. Pure ether very copiouſly diſſolves it, but ſeems to retain none of it when cold. Oil of turpentine has the ſame effect. With cauſtic potaſh it combines into a ſoap, ſoluble in warm water. Fluid ammonia, when cold, has no action upon it; but when warm, very eaſily diſſolves it, forming an emulſion, which is not decompoſed either by ſimple cooling, or by mixture with water; but the addition of an acid inſtantly precipitates the ſpermaceti. With concentrated ſulphuric acid it forms a browniſh ſolution, which, dropped into water, gives up its ſpermaceti, apparently unaltered. Like the other fat oils, it diſſolves ſulphur. By long expoſure to the air, it acquires a yellow tinge, and becomes rancid; but it may be again purified, by being waſhed in a warm ley of potaſs. The great uſe of ſpermaceti is for making candles; and it is alſo employed in medicine.

Spermaceti candles are of modern manufacture: they are made ſmooth, with a fine gloſs, free from rings and ſcars, ſuperior to the fineſt wax candles in colour and luſtre; and, when genuine, leave no ſpot or ſtain on the fineſt ſilk, cloth, or linen.

In medicine, ſpermaceti is demulcent and emollient; but for internal uſe it poſſeſſes no advantages ſuperior to thoſe of the bland oils. It is uſed in dyſentery and irritations of the alimentary canal, and alſo in catarrh and phthiſis; but in the latter caſes it is leſs beneficial than the bland oils. Some imaginary virtues have been aſcribed to ſpermaceti, which have occaſioned the uſe of it by women in child-bed. In its combination with water by means of the yolk of egg, it is a pleaſant vehicle for opium, when the after-pains are troubleſome. It forms a part of the compoſition of ſeveral ointments. The doſe is from ʒſs to ʒjſs, rubbed with ſugar, or in the form of emulſion. It poſſeſſes a property, which is that of ſoftening the ſkin, which has occaſioned its being uſed by the ladies in paſtes, waſhes, &c. Its officinal preparations are the "ceratum ſimplex" of the Edinb. Ph., formed of ſix parts of olive oil, three parts of white wax, and one part of ſpermaceti; the "ceratum cetacei" of the Lond. Ph. (ſee CERATUM); the "unguentum cetacei," or ſpermaceti ointment, of the Lond. Ph., formed by melting together, over a ſlow fire, ſix drachms of ſpermaceti and two drachms of white wax, and ſtirring them conſtantly till they be cold; and the "unguentum ſpermatis ceti," or ointment of ſpermaceti, of the Dubl. Ph., formed by making half a pound of white wax, one pound of ſpermaceti, and three pounds of prepared lard, into an ointment. Theſe ointments conſtitute the ordinary dreſſings for bliſtered ſurfaces and excoriations.

SPERMACOCE, in *Botany*, ſo named by Dillenius, in his *Hortus Elthamenſis* 369, from σπερμα, *ſeed*, and ακωκη, *a ſharp point*, in alluſion to the little erect beaks of the capſules.—Linn. Gen. 50. Schreb. 66. Willd. Sp. Pl. v. 1. 568. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 232. Purſh 105. Juſſ. 197. Lamarck Illuſtr. t. 62. Gærtn. t. 25.—Claſs and order, *Tetrandria Monogynia.* Nat. Ord. *Stellatæ*, Linn. *Rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſmall, ſuperior, with four teeth, permanent. *Cor.* of one petal, funnel-ſhaped; tube cylindrical, ſlender, longer than the calyx; limb in four deep, obtuſe, widely ſpreading, ſomewhat reflexed ſegments. *Stam.* Filaments four, awl-ſhaped, ſhorter than the corolla; anthers ſimple. *Piſt.* Germen inferior, roundiſh, compreſſed; ſtyle ſimple, divided in the upper part; ſtigmas obtuſe. *Peric.* Capſules two, combined, oblong, gibbous externally, flat on the inner ſide, obtuſe, each with two beaks. *Seeds* ſolitary, roundiſh, rolled in at the edges.

Eſſ. Ch. Corolla of one petal, funnel-ſhaped. Capſules two, combined, each crowned with two teeth.

A genus of extra-European weeds, not recommended by any beauty of aſpect, or known utility, chiefly the produce of the Weſt Indies, or the warmer parts of North America, a few ſpecies only being found in the Eaſt Indies. The plants are generally herbaceous, in many inſtances annual, often rough, with oppoſite, ſimple, entire *leaves;* ſheathing, membranous, jagged or briſtly, *ſtipulas*, like many of the ſame natural order; and numerous, ſmall, white, reddiſh, or blueiſh, whorled or capitate, *flowers*.

Eight ſpecies are enumerated in *Linn. Syſt. Veg.* ed. 14, of which the ſeventh, *S. procumbens*, is the ſame as *Hedyotis fruticoſa* of Linnæus. Willdenow has twenty ſpecies, to which three new ones are added by Purſh. Five find a place in the *Hortus Kewenſis.* We ſhall ſelect a few examples, ſufficient to give a general idea of the whole.

S. *tenuior.* Slender Button-weed. Linn. Sp. Pl. 147. Willd. n. 1. Ait. n. 1. (S. verticillis tenuioribus; Dill. Elth. 370. t. 277. f. 359.)—Stem ſmooth, erect. Leaves lanceolate; rough on the upper ſide. Flowers whorled. Stamens ſhorter than the corolla. Fruit hairy.—Native of the Weſt Indies. Found alſo, according to Purſh, in dry gravelly ſituations, from Virginia to Carolina, flowering from June to Auguſt. *Root* annual. *Stem* ſquare. *Leaves* an inch and a half long, lanceolate, acute. *Flowers* very ſmall, white.

S. *glabra.* Smooth Button-weed. Michaux Boreal-Amer. v. 1. 82. Purſh n. 2.—Stem ſmooth, procumbent. Leaves ovato-lanceolate, ſmooth on both ſides. Flowers whorled. Fruit ſmooth.—On the banks of rivers in moſt of the weſtern territories of North America, flowering in July and Auguſt. The plant is annual. *Flowers* white, longer than in the former.

S. *verticillata.* Denſe-whorled Button-weed. Linn. Sp. Pl. 148. Willd. n. 9. Ait. n. 4. (S. verticillis globoſis; Dill. Elth. 369. t. 277. f. 358.)—Hairy. Leaves lanceolate. Whorls globoſe, many-flowered.—Native of Africa. Cultivated by Sherard. The *ſtem* is ſhrubby, erect, branched, with numerous, narrow, ſomewhat cluſtered *leaves*, and denſe whorls of ſmall, white, very copious *flowers*. Such is the Senegal plant, deſcribed by Dillenius. The Jamaica ſpecimen from Brown, which is ſmooth, and which led Linnæus to admit that circumſtance into his ſpecific definition, may poſſibly be a different ſpecies, but we have not ſufficient materials to decide this point. Swartz ſpeaks of this laſt as having, when in flower, the ſmell of Melilot.

S. *hirta.* Rough Hairy Button-weed. Linn. Sp. Pl. 148. Willd. n. 12. Swartz Obſ. 45. (S. n. 3; Browne Jam. 141.)—Stem branched, hairy. Leaves ovato-lanceolate, rough with callous points. Flowers axillary, crowded, ſeſſile. Stamens prominent.—Native of dry graſſy places in the Weſt Indies. *Root* annual. Angles of the *ſtem* rough with recurved briſtly hairs. *Leaves* ſtalked, an inch and a half or two inches long, rough like a file, eſpecially on the upper ſide. *Stipulas* fringed with long taper briſtles. *Flowers* ſmall, whitiſh, with blue *anthers*. *Fruit* hairy.

S. *villoſa.* Shaggy Button-weed. Swartz Prodr. 29. Ind. Occ. 1943. Willd. n. 13. (Pulegium fruticoſum erectum, verticillis denſiſſimis; Sloane Jam. v. 1. 170.)—"Stem ſhaggy, ſlightly branched. Leaves ovato-lanceolate, downy; the uppermoſt four together. Flowers whorled. Stamens ſhorter than the corolla."—Native of fields and meadows, in the ſouthern part of Jamaica, flowering all the year round. The *ſtem* is herbaceous, a foot high, but little branched, ſquare, clothed with ſoft hairs. *Leaves* obtuſe, with briſtly ribs. *Flowers* white, with whitiſh, nearly ſeſſile, *anthers*. *Swartz.*

S. *procumbens.* Procumbent Corymboſe Button-weed. Linn. Syſt. Nat. ed. 12. v. 2. 115. Willd. n. 19. (S. corymboſa; Linn. Sp. Pl. 149.)—Stem procumbent. Leaves linear-lanceolate, entire, ſmooth-edged. Corymbs lateral, ſtalked, many-flowered.—Native of the Eaſt or Weſt Indies. Of this we have ſeen only an imperfect ſpecimen, in the Linnæan herbarium, which we ſhould rather gueſs to belong to *Hedyotis*, but the *fruit* is not in a ſtate to decide that queſtion. The *leaves* are an inch long. *Flowers* in roundiſh corymboſe heads, compoſed of crowded leafy whorls, on axillary compreſſed ſtalks. *Calyx* recurved, downy. *Corolla* hairy within. *Stamens* prominent.

S. *hyſſopifolia.* Hyſſop-leaved Button-weed. Sm. Inſ. of Georgia, v. 1. 75. t. 38.—Stem decumbent. Leaves linear-lanceolate, fringed with briſtly teeth. Whorls of few flowers.—Native of Surinam and Georgia. A ſpecimen was ſent by Rolander to Linnæus, who marked it *S. ſtrigoſa*, but afterwards effaced that name, nor does this ſpecies ſeem to have been any where deſcribed, till it appeared in the Natural Hiſtory of the Inſects of Georgia, with the plants on which they feed, publiſhed by the writer of this article, from the drawings and papers of Mr. John Abbot. This work is never cited by Willdenow, nor perhaps had it fallen in his way. The ſpecies before us has woody, wavy, decumbent, ſlightly branched, ſmoothiſh *ſtems*. The *leaves* are an inch long, remarkable for being bordered with fine cartilaginous teeth, pointing forward, like thoſe of many ſpecies of *Galium*. Briſtles of the *ſtipulas* numerous, long, and ſtout. *Flowers* reddiſh, three or four in each whorl. *Calyx* fringed. *Fruit* obovate, roughiſh, red even in an early ſtate, though the *calyx* is green. We ſhould ſuſpect this to be the *S. diodina* of Michaux and Purſh, found in dry barren ſoils, on iron ore hills, from Virginia to Carolina, but the *flowers* of that ſpecies are deſcribed as white, and very ſmall, ſolitary and alternate, the *ſtem* and *ſeeds* hairy, which characters do not anſwer to our plant, though the edges of the *leaves* appear to be ſimilarly rough in both.

S. *involucrata*. Long-flowered Button-weed. Purſh n. 4.—" Stem alternately branched, very hiſpid. Leaves ovato-lanceolate, pointed, hairy on both ſides. Stipulas with many briſtles. Heads terminal, bracteated. Stamens prominent."—Found in Carolina by Mr. Fraſer. About a foot high. *Leaves* broad, rather oblique. *Flowers* white, with a very long tube.

SPERMACOCE, in *Gardening*, contains plants of the herbaceous, annual, and ſhrubby kinds; among which the ſpecies cultivated are, the ſlender button-weed (S. tenuior); and the whorl-flowered button-weed (S. verticillata).

Method of Culture.—Theſe plants are increaſed by ſowing the ſeeds on a moderate hot-bed, early in the ſpring, or in pots to be plunged in it. When the plants have attained ſome growth, they ſhould be removed into ſeparate pots, filled with good friable mould, replunging them in the bed. They ſhould afterwards be managed as other plants of the exotic ſtove kind.

They afford variety in hot-houſe and ſtove collections.

SPERMATIC, in *Anatomy*, an epithet applied to various parts belonging to the teſticle, as the artery, veins, nerves, cord, &c. See the deſcription of the teſtis in the article GENERATION.

SPERMATIC *Chord, Diſeaſe of*, in *Surgery*. See HYDROCELE.

SPERMATOCELE, a kind of rupture, occaſioned by a diſtenſion of the ſeminal veſſels, by which they are let fall into the ſcrotum.

SPERMATOPŒA, a name given to ſuch medicines as are ſuppoſed to increaſe the ſemen.

SPERMATOSIS is a term ſometimes uſed for the formation of ſeed.

SPERONE, LA, in *Geography*, a cape at the ſouth-eaſt extremity of Corſica; 4 miles E. of Bonifacio.

SPERONI, SPERONE, in *Biography*, a diſtinguiſhed Italian writer of the 16th century, was the ſon of Bernardino Speroni, a noble of Padua, in which city he was born in the year 1500. He ſtudied under the famous Pomponazzo, in Bologna. He took his degrees in medicine and philoſophy, and was appointed at an early age reader in logic, and profeſſor of philoſophy, in the univerſity; but being greatly attached to his former preceptor Pomponazzo, he returned to Bologna, which he did not quit till the death of that eminent man. He then reſumed the profeſſor's chair at Padua, which he held till the death of his father in 1528, and his own marriage. After this he was employed by his fellow-citizens in public buſineſs, and was entruſted with ſeveral honourable commiſſions. But he was not leſs intent upon literature than diligent in active buſineſs, and became one of the moſt learned men of his time. When reſiding as an envoy at Venice, his ſpeeches before the ſenate were ſo much admired, that it has been affirmed, that the judges and advocates belonging to other courts would leave their own places, to hear his pleadings. Neverthelefs he was not a lawyer by profeſſion, but only took up, occaſionally, the cauſes of his friends. In 1560 Speroni went to Rome, as agent to the duke of Urbino at the Papal court. He obtained the friendſhip of the principal men of letters at that capital, and was on terms of particular intimacy with Charles Borromeo; and on that account he was induced to add theology to his other ſtudies. Pius IV. conferred on him the honour of knighthood; and the dukes of Urbino and Ferrara ſent for him to their different courts, where he was treated with the greateſt reſpect. Almoſt all the princes of Italy followed the example of thoſe ſovereigns, intreating him to take up his abode with them; but he preferred the tranquillity of private life to the honours that might have been ſhowered upon him. He died at the great age of 88, and was interred with every kind of funeral honour. As a writer, his ſtyle is ſpoken of with ſingular approbation: it is ſaid to be entirely free from the affected elegance and the prolixity which characterize many authors of that country and period. It rather ſeems purpoſely to ſhun the moſt ornamented expreſſions, and yet it is inferior to none in true poliſh, and unites gravity and preciſion to harmony and eloquence. One of the moſt celebrated compoſitions of Speroni was a tragedy, entitled "Canace and Macareus," which was much applauded by the Paduan academy degli Inflammati. Some copies of it having got abroad without the knowledge of the author, an incorrect edition was printed at Venice in 1546, but with the imprint Florence. Before, however, this ſurreptitious publication, there appeared in MS. a criticiſm upon it, in which it was treated with ſingular ſeverity. This being afterwards printed, Speroni thought it neceſſary to defend his compoſition, and a long controverſy enſued. The author, no doubt, improved his work before he gave it to the public, ſanctioned by his own authority; and when it thus appeared, it was regarded as one of the beſt productions of that claſs which the age exhibited. Of the other writings of this author, many are moral treatiſes in the form of dialogue, in which he was one of the firſt compoſers in Italian, and in which he is ſaid to have had few equals. The reſt related to polite literature, eloquence, poetry, hiſtory, &c.; all diſplaying an extenſive knowledge of books, and a correct judgment. His works have been collected and publiſhed at Venice, in 5 vols. 4to.

SPERVERIUS, in *Ornithology*, a name by which Bellonius, and ſome other authors, have called the ſparrow-hawk, more commonly known by the names of *niſus*, and *accipiter fringillarius*.

SPESSART, in *Geography*, a large foreſt of Germany, to the right of the Mayne, extending from Wurzburg to Aſchaffenburg.

SPETKER, a river of Switzerland, belonging to the abbey of St. Gal; 4 miles E. of St. Gal.

SPEUSIPPUS, in *Biography*, an Athenian philoſopher, ſon of Eurymedon, by a ſiſter of Plato, ſucceeded his uncle in his ſchool, over which he preſided during eight years, commencing from the death of that illuſtrious philoſopher, in the year B. C. 348. He placed the ſtatues of the Graces in the ſchool built by Plato in the academy, and cloſely adhered to the doctrines of his maſter. His manners, however, were not conformable to his philoſophy: he was vindictive, and a lover of pleaſure. He was likewiſe avaricious, and, contrary to the practice of Plato, exacted a gratuity from his diſciples. He was admitted to the friendſhip of Dion while he reſided at Athens; and it was by his inſtigation that Dion, invited by the malecontents of Syracuſe, undertook his expedition againſt Dionyſius. (See Dion. in Vit. Corn. Nep.) Becoming paralytic in his limbs, he was conveyed to and from the academy in a carriage of ſome kind. Upon one of theſe occaſions he met Diogenes, and ſaluted him; but the cynic, inſtead of returning the civility, upbraided him for enduring to live under ſuch an infirmity. To which Speuſippus replied, "that he did not live in his limbs, but in his mind." At length, overcome by his maladies, and wearied of life, he put an end to his exiſtence, having firſt conſtituted Xenocrates his ſucceſſor in the academy. He was author of ſeveral philoſophical treatiſes, which have periſhed; though it is ſaid that they were held in ſuch eſtimation by Ariſtotle, that he gave three talents for them.

SPEY, in *Geography*, a river of Scotland, which riſes in the loch of that name, about eight miles S.W. from Fort Auguſtus, in the county of Inverneſs, and runs into the North ſea, in the frith of Murray; 3 miles N.W. of Fochabers. N. lat. 57° 40′. W. long. 2° 59′.

SPEYERSBERG, a town of Bavaria, in the biſhopric of Bamberg; 11 miles N. of Bamberg.

SPEYMOUTH, a pariſh of the ſhire of Elgin, Scotland, 1½ mile N.W. from Fochabers.

SPEZZA, or SPETIA, a ſea-port town of the Ligurian republic, ſituated on a gulf of the Adriatic, to which it gives name, and anciently called "Portus Lunæ." At the entrance of the gulf is a ſmall iſland, called "Palmaria," which makes the harbour ſafe and large; 35 miles S.E. of Genoa. N. lat. 44° 9′. E. long. 9° 40′.

SPEZZANO, a town of Italy, in the department of the Panaro; 5 miles S. of Modena.—Alſo, a town of Naples, in Calabria Citra; 4 miles E.N.E. of Coſenza.

SPHACELUS, from σφαζω, *to deſtroy*, implies, in *Surgery*, the complete mortification of a part of the body. See GANGRENE.

SPHACHIA, in *Geography*, a diſtrict or province of the iſland of Crete, lying towards the ſouth, and extending to the eaſt much more than Cidonia, or Kidonia, which is ſituated to the north; it is conſidered as making part of the pachalic of Candia; though the interior police and adminiſtration belong to the inhabitants themſelves, called "Sphachiots." The firſt chain of the high mountains of Sphachia, compriſed in the province of Kidonia, is covered with ſnow for four or five months. It is, in general, ſtony and deſtitute of earth; but it has a few narrow vallies which are ſuſceptible of culture. Barley is ſown here in May, and gathered in September. As ſoon as the ſnow is melted, the flocks are brought to theſe mountains; and though the ground appears almoſt naked, cattle find a food, which, if not abundant, is very reliſhing, and very fit for giving to their milk and fleſh a quality, unattainable by thoſe that are bred in the moſt fertile places. The Sphachiots inhabit the high mountains, which extend from E. to W., from the province of Selino, as far as that of Amari. Independently of a great number of villages, which are ſituated on theſe mountains, ſome are found towards the ſouth coaſt, and among others "Sphachia," their chief place, which is a ſmall harbour that contains ſeven or eight large boats, which the Sphachiots uſe for their trade, and ſometimes alſo for the piracies which they practiſe in imitation of their anceſtors. The Malteſe formerly frequented this harbour, and were furniſhed by the inhabitants with proviſions, and all the aſſiſtance which they wanted. Sphachia produces ſcarcely any oil; but it affords a ſmall quantity of wheat, and barley in greater abundance: it alſo furniſhes honey and wax. The principal production conſiſts in little cheeſes made with ewes' milk, which are exported to Conſtantinople. In winter the Sphachiots drive their flocks to the ſea-ſide, in order to obtain plenty of graſs; but in ſummer they remove them back to feed on the rich paſtures, which the milder temperature and gradual melting of the ſnow always maintain in a ſtate of verdure. With the wine which theſe Greeks make on the firſt link of the chain of their mountains, they indulge themſelves ſo freely, that they conſume their whole ſtock during the three or four months that ſucceed the vintage, and in the remainder of the year they are obliged to drink pure water. The inhabitants of the Sphachian mountains are diſtinguiſhed by their induſtry and activity; they are ſhepherds, agriculturiſts, and artiſans; they occupy their land to advantage, and breed a great number of cattle; and manufacture with tolerable ſkill the cloths which they uſe, as well as the utenſils and implements which they employ. Upon the whole, the Sphachiot has preſerved the energy of the independent man, and the activity of a perſon who enjoys, without moleſtation, the fruit of his labour.

The Sphachiots, who are conſidered as the real deſcendants of thoſe famous Cretans who were ſo long maſters of the country, are diſtinguiſhed from the other Greeks by their tall ſtature, their comely appearance, their love of liberty, their courage, their ſkill, and, above all, the hatred which they have vowed againſt the uſurpers of this iſland. Under the Romans, the Saracens, the Venetians, and the Turks, the Sphachiots found means to preſerve their laws and their cuſtoms. They annually appointed their magiſtrates in the general aſſemblies of the people. Obliged by the Turks to tranſport, in ſummer, from the top of their mountains, the ice neceſſary for the conſumption of the inhabitants of Canea and Retimo, they paid no tax, no impoſt; they had no agas; they never ſaw among them the agents of the Turkiſh government; they formed, in a word, a republic in ſome meaſure independent. When, in 1769, ſome Ruſſian emiſſaries came to diſturb the peace, and impair the happineſs, which theſe privileged Greeks enjoyed on their mountains, the Sphachiots recurred to arms; and ſome hundreds of the braveſt of them went and joined the Mainots, their friends, and proceeded together to offer their ſervices to count Orloff, at a time when they apprehended the Ruſſians were preparing to deliver the Greeks from the Ottoman yoke. The paſha of Candia, informed of the conduct of the Sphachiots, reſolved, in the ſame year 1770, to march againſt them with all the forces of the iſland. He wiſhed to exterminate them, and thus to afford a terrible example of ſeverity to all the Greeks who might be tempted to imitate them. The Turks ſoon united under their colours. The Sphachiots, taking advantage of their rocks and mountains, defended themſelves againſt the attacks of the Turks, and ſheltered themſelves amidſt their crags and precipices. Notwithſtanding their reſiſtance, the Turks perſevered, though tired of a painful and diſagreeable war, and loudly demanding to return home, reduced the Sphachiots to the laſt extremity. Almoſt all their villages were ſet on fire; many of their women and children were carried off, as well as their flocks, and their proviſions were exhauſted. In theſe circumſtances they received with pleaſure the firſt propoſals that were made to them, conſented to pay their annual tribute, and obtained permiſſion to return to their habitations, and continue their barter with the maritime towns. The Turks treated them in the moſt inſulting and cruel manner, loading 3000 or 4000 Greeks with their baggage, and in their different battles placing them in front, ſo as to make a rampart of their bodies. This cowardly and barbarous treatment greatly diſtreſſed theſe brave mountaineers; and frequently prevented their firing on their enemies, for fear of injuring thoſe whom they conſidered as their brethren, ſtill more unfortunate than themſelves. Although the Sphachiots pay their karatch with the greateſt repugnance, and are diſpoſed to avail themſelves of the firſt favourable moment for ſhaking off the yoke, which hangs heavy on their necks, they took care, during the laſt war of the Ruſſians againſt the Turks, to reſiſt the ſolicitations addreſſed to them for taking a part in any hoſtile armaments. By this wary conduct, they have preſerved the few privileges which they have remaining. Olivier's Travels.

SPHÆCULÆ, among the Romans, were tickets of wood, *teſſeræ ligneæ*, by which the emperors ſcattered their preſents to people of both ſexes in the theatre, or circus.

SPHÆRANTHUS, in *Botany*, derived from σφαιρα, *a ſphere*, or *globe*, and ανθος, *a flower*, from the aggregation of its florets into globular heads.—Linn. Gen. 452. Schreb. 591. Willd. Sp. Pl. v. 3. 2394. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 184. Juſſ. 176. Lamarck Dict. v. 7. 321. Illuſtr. t. 718. Gærtn. t. 164. Loureir. Cochinch. 509. Vaill. Mem. de l'Acad. des Sc. 1719. t. 20. f. 12.—Claſs and order, *Syngeneſia Polygamia Segregata*. Nat. Ord. *Compoſitæ Capitatæ*, Linn. *Cinarocephalæ*, Juſſ.

Gen. Ch. *Common Calyx* globular, imbricated with pointed, permanent ſcales, clothing the general receptacle on all ſides; *partial* one to each ſcale of the common calyx, many-flowered, of five linear, equal, erect leaves. *Cor. partial* compriſing about three perfect florets in the diſk, and moſtly five female ones in the radius. *Perfect florets* of one petal, funnel-ſhaped, with a five-cleft, ſpreading limb; *female* awl-ſhaped, tubular, with a trifid, very ſmall, cloſed mouth. *Stam.* (in the perfect florets) Filaments five, capillary, very ſhort; anthers cylindrical, tubular, longer than the corolla. *Piſt.* (in the perfect florets) Germen ſhrivelled; ſtyle long and rather thick; ſtigma quite ſimple: (in the female florets) Germen oblong; ſtyle ſetaceous, the length of the ſtamens; ſtigma cloven. *Peric.* none, except the unchanged calyx. *Seeds* (in the perfect florets) none; (in the female) ſolitary, oblong, naked. *Recept. common* ſcaly; *partial* naked.

Eſſ. Ch. Partial calyx eight-flowered. Florets tubular, perfect; ſome imperfectly female. Receptacle ſcaly. Down none.

1. S. *indicus*. Indian Sphæranthus. Linn. Sp. Pl. 1314. Fl. Zeylan. 312. Willd. n. 1. (S. purpurea alata ſerrata; Burman. Zeylan. 220. t. 94. f. 3.)—Leaves lanceolate, ſerrated, decurrent, ſmooth. Peduncles winged. Wings of the ſtem and ſtalks ſerrated.—Native of the Eaſt Indies. It flowers at Kew, in the ſtove, from Auguſt to December. *Root* perennial. *Stems* herbaceous, branched above and below, ſmooth. *Leaves* alternate, ſeſſile, lanceolate, naked, ſerrated, remarkably decurrent, involute, having the fragrance of oil of lavender. *Flowers* ſolitary, terminal, globular, of a blue or purpliſh colour.

2. S. *microcephalus*. Small-headed Sphæranthus. Willd. n. 2.—Leaves obovato-lanceolate, ſlightly pointed, ſerrated, decurrent, ſmooth. Peduncles winged. Wings of the ſtem and ſtalks entire.—Native of Java.—Willdenow, upon whoſe authority this and the following ſpecies are adopted, ſays, that this is very like the preceding, but that its *wings* are entire, not ſerrated. *Leaves* obovato-lanceolate, obtuſe, with minute, very diſtant, pointed ſerratures. *Flowers* in oblong, not ſpherical, heads, about half as big as thoſe of the laſt ſpecies.

3. S. *hirtus*. Hairy Sphæranthus. Willd. n. 3. Lamarck Illuſtr. t. 718. f. 1.—Leaves obovate, ſerrated, hairy, decurrent. Peduncles winged.—Allied to the firſt ſpecies, but diſtinct in having obovate *leaves*, and ſmaller *heads of flowers*, as well as in the hairineſs of all its parts.

4. S. *africanus*. African Sphæranthus. Linn. Sp. Pl. 1314. Thunb. Prodr. 169. (Scabioſa minor, alato caule, maderaſpatenſis; Pluk. Alm. 335. t. 108. f. 7.)—Leaves decurrent, ovate, ſerrated. Peduncles round.—Native of the Cape of Good Hope and Madras, flowering at Kew in July and Auguſt. *Stem* herbaceous, about ten inches high. *Leaves* alternate, ovate-lanceolate. *Peduncles* ſuſtaining three or four globular *heads of flowers* of a pale yellow colour.

5. S. *chinenſis*. Linn. Mant. 119. Willd. n. 5.—Leaves ſeſſile, pinnatifid.—Native of India. Why then (ſays profeſſor Martyn) is it named *chinenſis*?—It is extremely like *S. indicus*, but a much ſmaller plant, with pinnate, ſinuated *leaves*, and, if we miſtake not, is the very ſame as the Linnæan *Artemiſia maderaſpatana*.

6. S. *cochinchinenſis*. Loureir. Cochinch. 510.—Leaves decurrent, oblong, undivided. Flowers in heart-ſhaped, ovate, nearly ſeſſile, terminal heads.—Native of China and Cochinchina, among corn, and in gardens.—Stem herbaceous, a foot and half high, erect, round, ſmooth, whitiſh, with a few aſcending branches. *Leaves* alternate, ſeſſile, undulated, rugoſe, woolly. *Flowers* white, tinged with a little purple. Loureiro obſerves, that the laſt ſpecies (*S. chinenſis*) differs from this only in having pinnatifid leaves.

SPHÆRIA, a genus of the fungus tribe, defined by Micheli, but properly named by Haller, in alluſion to the ſpherical ſhape of the ſeed-veſſels.—Hall. Hiſt. v. 2. 120. Schreb. Gen. 770. Perſ. Syn. 1. Lamarck t. 879. (Lichen-agaricus; Mich. Gen. 103. t. 54, 55.)—Claſs and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi, angiocarpi*.

Eſſ. Ch. *Capſules* roundiſh, immerſed, filled with jelly, which becomes a maſs of minute, volatile, *ſeeds*.

Perſoon reckons up 184 ſpecies, diſtributed in eight ſections, of each of which we ſhall exhibit examples.

Sect. 1. *Cauleſcent; elongated or club-ſhaped; their ſubſtance either fleſhy or corky*. Ten ſpecies.

S. *militaris*. Scarlet Club-ſhaped Sphæria. Perſ. n. 1. Obſ. Mycolog. faſc. 2. 66. t. 6. f. 3. Sowerb. Fung. t. 60. (Clavaria militaris; Linn. Sp. Pl. 1652. Hudſ. 638. With. v. 4. 361? C. militaris crocea; Vaill. Pariſ. 39. t. 7. f. 4. C. granuloſa; Bulliard t. 496. f. 1.)—Tawny red, or ſcarlet, fleſhy, club-ſhaped. Head granulated with the prominent ſeed-veſſels. Perſoon mentions this as found in autumn, after great rains, in wet graſſy places, always growing out of ſome dead caterpillar or chryſalis. The only ſpecimen we ever ſaw was gathered on a dry gravelly bank above Thorpe, near Norwich, and meaſured about an inch in height, the head being ovate, of a beautiful ſcarlet, granulated like orange-peel; the ſtalk paler and ſmooth. The figures above cited are rather taller, and generally more yellowiſh. Withering appears to confound various diſtinct ſpecies under the above name.

S. *entomorhiza*. Slender-ſtalked Sphæria. Dickſ. Crypt.

faſc. 1. 22. t. 3. f. 3. Perſ. n. 4. With. v. 4. 389.—Stalk elongated, ſlender, ſimple or divided, ſomewhat compreſſed. Head roundiſh, brown.—Found by the late Rev. Mr. Lightfoot, in the woods of the ducheſs dowager of Portland at Bulſtrode, in autumn, but rarely, growing out of ſome dead inſect. The *ſtalk* was uſually two or three inches high, wavy, ſlender, blackiſh; ſometimes deeply cloven. *Heads* ſolitary, globular, granulated, browniſh, the ſize of a ſmall pea.

S. *ophiogloſſoides.* Fibrous-rooted Club Sphæria. Perſ. n. 5. (Clavaria radicoſa; Bulliard t. 440. f. 2. C. paraſitica; Willden. Berolin. 405. t. 7. f. 17. With. v. 4. 361.)—Stalk ſimple, yellowiſh, with a branched fibrous root. Head oval, turgid, black.—Native of ſandy heaths, or fir woods, in autumn. Mr. Pitchford found it near Norwich, many years ſince, nor can there be any doubt reſpecting the above ſynonyms. His ſpecimens, like thoſe of Willdenow, grew paraſitically, on the *Tuber cervinum*, one or two on each individual, to which they were attached by their long and much-branched fibrous roots. The *ſtalk*, about two inches high, is wavy or curved, roundiſh, of a dirty yellow, as well as the *root*. *Head* an inch long, when full grown, granulated, of a glaucous black, ſolid; pale yellow within.

S. *Hypoxylon.* Horned Black Sphæria. Perſ. n. 7. Obſ. Mycolog. faſc. 1. 20. t. 2. f. 1, *a, f.* Sowerb. Fung. t. 55. (Clavaria Hypoxylon; Linn. Sp. Pl. 1652. Hudſ. 639. With. v. 4. 369. C. cornuta; Bulliard t. 180.)——Cluſtered, branched, compreſſed; black and hairy below; whitiſh and dilated at the ſummits.—Common on rotten ſtumps or poſts, in woods and gardens, making a conſpicuous appearance. Its uſual height is three or four inches. The hairineſs is moſt copious and coarſe on young plants. In winter the ſummits of the branches are plentifully covered with white powder, but deſtitute of the ſpherical ſeed-veſſels. The latter, according to Perſoon, are perfected in ſummer. His obſervations contradict the opinion reported by Withering after Dr. Waller, that the preſent ſpecies is the male of the following. Indeed that opinion is much invalidated by the aſſertion that *Clavaria ophiogloſſoides* of Linnæus, (ſee GEOGLOSSUM,) is only a variety of the *digitata*. Such a miſtake is no otherwiſe accountable, than by ſuppoſing the perſon who made it took the ſpecies laſt deſcribed for the *Geogloſſum*, and even then his accuracy of judgment could not rank high.

S. *digitata.* Finger-ſhaped Black Sphæria. Sowerb. Fung. t. 69. (S. polymorpha; Perſ. n. 10. Clavaria digitata; Linn. Sp. Pl. 1652. Hudſ. 639. With. v. 4. 368. Bulliard t. 220. Lichen-agaricus terreſtris digitatus niger, &c.; Mich. Gen. 104. t. 54. ord. 2. f. 4.)—Cluſtered, club-ſhaped, obtuſe, tumid, coal-black. Frequent on old rotten ſtumps in beech woods, as well as on old poſts of different kinds, into which its long perennial roots deeply inſinuate themſelves, the fungus ſpringing up every autumn, in the ſhape of numerous, ſimple or divided, hard, black, rough, finger-like bodies, whitiſh at the ſummit while young, and tapering below into very ſlender ſtalks. Perhaps *S. digitata*, Perſ. n. 9, may be a variety only; but the Linnæan ſynonym belongs to what we have deſcribed.

Sect. 2. *Roundiſh or diffuſe, without a ſtem.* Thirteen ſpecies.

S. *concentrica.* Concentric Black Sphæria. Perſ. n. 11. Bolt. Fung. t. 180. (S. fraxinea; With. v. 4. 393. Sowerb. Fung. t. 160. Lycoperdon fraxineum; Hudſ. 641; excluding the ſynonym of Micheli.)—Roundiſh, tumid, firm, ſmooth, with numerous concentric internal layers. Frequent on the decayed ſtumps of Aſh, Willow, and other trees. Uſually coal-black, ſomewhat ſhining, in globular maſſes, the ſize of a cheſnut, or larger, and of the ſubſtance and lightneſs of charcoal.

S. *fragiformis.* Orange Sphæria. Perſ. n. 13. (Lycoperdon varioloſum; Linn. Syſt. Nat. ed. 12. v. 3. 234. Hudſ. 645. Sowerb. Fung. t. 271.)—Cluſtered, ſomewhat confluent, of a ruſty red; black and ſhining within. Seed-veſſels minutely papillary, in the deciduous coat.—Frequent on rotten branches and ſtumps in damp woods. Each plant is the ſize of a pea, more or leſs, bright red when young. In an advanced ſtate they become confluent, of a brick colour, and the coat, in which the minute ſeed-veſſels are lodged, ſcales off, leaving a black central maſs, miſtaken by Mr. Sowerby for the ſeed.

Sect. 3. *Shape roundiſh, but various and indeterminate. Capſules ſcattered horizontally, with prominent orifices, often ſpinous.* Twenty-three ſpecies.

S. *poronia.* Dotted Cup Sphæria. Perſ. n. 24. (S. punctata; Sowerb. Fung. t. 54. Peziza punctata; Linn. Sp. Pl. 1650. Bulliard t. 252.)—Stalked; cup-ſhaped, ſhallow, white in the diſk, with black ſcattered ſunk capſules.—Found in ſandy countries, chiefly on horſe-dung, rarely on that of cows. It looks like a ſtalked *Peziza*, ſcarcely half an inch broad, conſpicuous for its white diſk, dotted with the black ſeed-veſſels. The ſubſtance is firm, or leathery.

S. *deuſta.* Large Spreading Sphæria. Perſ. n. 25. (S. maxima; Web. Goett. 286. Dickſ. Crypt. faſc. 1. 23. S. verſipellis; Tode Mecklenb. v. 2. 55. t. 17. f. 129. Hypoxylon uſtulatum; Bulliard t. 487. f. 1. Lichen-agaricus cruſtaceus craſſus, bovinum renem veluti repræſentans, niger et quaſi deuſtus; Mich. Gen. 104. t. 54. f. 1.)—Broad, indeterminate, thick, wavy and tumid; at firſt grey and powdery; finally black and rigid. Capſules ſunk.—Not uncommon on old rotten ſtumps, over which it ſpreads, to the extent of two or three inches, in thick, diffuſe, unequal maſſes, finally coal-black, and of the texture of *S. concentrica*, (ſee the preceding ſection,) with which Hudſon and ſome other botaniſts have confounded it. The ſhape, however, is not globoſe, nor is the internal ſubſtance formed of concentric layers. The *capſules* moreover are larger, and very conſpicuous in a vertical ſection of the plant, being cloſely ranged, in a ſimple ſeries, under the external coat, through which their *ſeeds* are diſcharged by a ſlender tube belonging to each capſule.—Perſoon remarks, that this ſpecies ſometimes acquires a kind of ſtalk, when growing on very rotten wood, or on the ground near an old ſtump.

S. *ceratoſperma.* Horn-ſeeded Sphæria. Perſ. n. 38. (S. Ceratoſpermum; Tode Mecklenb. v. 2. 53. t. 17. f. 131. Ceratoſpermum nigrum minimum diſcoides, e diverſarum arborum ramorum emortuarum corticibus, et præcipuè corylo erumpens; Mich. Gen. 125. t. 56. f. 1.)—Roundiſh, convex, ſcattered, black. Capſules with long prominent beaks.—Found by Micheli in woods near Florence, chiefly on dead branches of hazel, in the winter. Tode obſerved it in July, on the dead bark of *Roſa canina.* Each plant is leſs than a ſplit pea, ſeated on the dead wood or bark, under the cuticle, and ſoon becomes diſtinguiſhed by the protruſion of numerous little black horn-like excreſcences, which appear to be the prominent beaks of the ſunk *capſules.* Tode's figures, however, do not preciſely accord with thoſe of Micheli. We once examined the original ſpecimens of the latter writer, but the horn-like proceſſes had diſappeared; nor have we met with any thing in England anſwerable to this ſpecies, though many which belong to Perſoon's eighth, or laſt, ſection are ſufficiently ſimilar in their mode of growth to explain the nature of that before us.

Sect. 4. *Shape indeterminate. Capſules horizontal; at firſt marginal, and ſeparate; afterwards confluent.* Twenty-four ſpecies.

Perſoon himſelf doubts the certainty of this ſection, ſome of the ſpecies ſeeming rather to belong to that immediately preceding, others perhaps to the eighth.

S. *graminis.* Graſs Sphæria. Perſ. n. 50. Obſ. Mycol. faſc. 1. 18. t. 1. f. 1 and 2.—Linear-oblong, forming ſhining black ſpots upon leaves. Capſules globoſe, without prominent beaks.—Obſerved by Perſoon on the leaves of *Elymus europæus* and *Lolium perenne*, in the ſhape of oblong, black, ſlightly prominent ſpots, various in length, which, when cut vertically, diſplay a ſeries of ſunk globular *capſules*, not projecting above the ſurface.

The reſt of this ſection are ſimilarly paraſitical on the leaves or ſtalks of various plants.

Sect. 5. *Capſules crowded into an elevated tuft, on a common cruſtaceous receptacle; their beaks converging.* Fifteen ſpecies.

S. *ferruginea.* Ruſty-cruſted Sphæria. Perſ. n. 62. Obſ. Mycol. faſc. 1. 66. t. 5. f. 1, 2.—Capſules black, with taper ſtraight beaks; their baſes ſurrounded with ruſty powder.—Gathered by Perſoon, on dry branches of hazel. It burſts from under the cuticle in little oblong tranſverſe prominent maſſes, of which nothing appears but the taper ſpine-like beaks of the little black *capſules.* When laid bare, a powdery ruſty maſs, like a cruſt, is found to accompany the capſules, but Perſoon ſuſpects this may poſſibly originate from the wood. His figure is admirable, as uſual with all that he has publiſhed.

Sect. 6. *Capſules ranged circularly, moſtly decumbent, without a cruſt, lodged under the cuticle of plants, their orifices generally crowded together.* Fourteen ſpecies, which might perhaps have been comprehended in the laſt ſection.

S. *convergens.* Converging Sphæria. Perſ. n. 86. Tode Mecklenb. v. 2. 39. t. 14. f. 111.—Aggregate, ſlightly prominent. Capſules black, ovate, with ſtraight beaks, all meeting in a point.—On the branches of trees, eſpecially between the bark and cuticle of beech when dry. It conſiſts of little black tubercular ſpots, each formed of a few minute *capſules*, ranged circularly, whoſe beaks, about their own length, meet in a conical point. There are no traces of any cruſt, or common baſis.

S. *ſalicina.* Aggregate Willow Sphæria. Perſ. n. 88. Obſ. Mycol. faſc. 1. 64. (S. cancellata; Tode Mecklenb. v. 2. 34. t. 13. f. 107.)—Aggregate, circular. Mouth of the capſules concreted into a rugged perforated diſk.—Not rare on dead dry branches of Willows, according to Tode and Perſoon, giving them the roughneſs of a file when handled. The minute black *capſules* are ſo combined at their orifices, eight or ten in each circular aſſemblage, as to form one body, united by a rugged or reticulated, woody or fungous, ſubſtance, of a grey or dirty white.

Sect. 7. *Capſules diſtinct, forming a roundiſh tuft, on a common receptacle, and burſting through the cuticle of plants.* Eleven ſpecies.

S. *coccinea.* Scarlet Sphæria. Perſ. n. 92. (S. decidua; Tode Mecklenb. v. 2. 31. t. 13. f. 104.)—Tufted, pale red. Capſules ovate, ſmooth.—Said to be not unfrequent on dead branches of beech; conſiſting of ſcattered oval tufts, half the ſize of a pea, bordered by the reflexed torn cuticle of the branch. The *capſules* are minute, half ſunk in the tumid receptacle, each with a ſhort beak. There is a larger and brighter-coloured variety, found by Dr. Roth on the elder.

S. *populina.* Poplar Sphæria. Perſ. n. 94. Obſ. Mycol. faſc. 2. 67. t. 5. f. 10, 11.—Tufted, black. Capſules numerous, ovate, ſmooth, ſomewhat ſpreading, ſeated on a denſe receptacle.—On the branches of poplars, but not common. It forms little black ſcattered tufts, each compoſed of 25 or 30 ovate, pointed, ſeſſile *capſules*, divaricated at the points, and, though crowded, quite unconnected at the baſe.

S. *aucupariæ.* Mountain-aſh Sphæria. Perſ. n. 96. (S. cæſpitoſa; Tode Mecklenb. v. 2. 41. t. 14. f. 113.)—Tufted, black, powdered with white. Receptacles aggregate, palmate, each bearing ſeveral cylindrical capſules.—On dead branches of the mountain-aſh in May. This burſts in round, black, hard maſſes, from under the cuticle of the tree, each the ſize of a vetch-ſeed. When magnified, each tuft appears to conſiſt of many hand-ſhaped erect portions, whoſe finger-like points are ſuppoſed to be the *capſules*; but the whole ſeems a very obſcure production, nor has it ever fallen under our obſervation.

Sect. 8. *Capſules ſolitary, diſtinct, deſtitute of a receptacle.* Eighty-three ſpecies, ſubdivided according to the ſhape or proportion of the mouths, or beaks, of the capſules.

S. *pileata.* Cap Sphæria. Perſ. n. 102. (S. macroſtoma, var. ε, pileata; Tode Mecklenb. v. 2. 13. t. 9. f. 78.)—Simple, globoſe; its mouth inverſely conical, flat at the top, with a linear orifice.—Found ſunk in the bark of dead branches of trees, in the early ſpring. *Tode.* The ſize of poppy-ſeed, black and ſmooth, crowned with a diſcoid dilatation, in which the mouth is ſeated.

S. *dehiſcens.* Wide-mouthed Sphæria. Perſ. n. 106. (S. macroſtoma, var. α, β, γ; Tode Mecklenb. v. 2. 12. t. 9. f. 76.)—Simple, globoſe, immerſed; its mouth compreſſed, with tumid lips.—Found ſunk in the wood itſelf of rotten branches of trees, in the month of April. Very near the laſt, from which Tode conſidered it as not ſpecifically diſtinct. The only difference conſiſts in the leſs prominent, and not conical, form of the lips of the capſule.

S. *roſtrata.* Needle-beaked Sphæria. Perſ. n. 112. Tode Mecklenb. v. 2. 14. t. 9. f. 79.—Simple, naked, globoſe, granulated, with a very long taper-pointed beak.—Found more or leſs immerſed in rotten beech wood. Each plant conſiſts of a globular, rugged, black, thickly coated *capſule*, the ſize of coarſe ſand, with a curved, ſharp, ſlender beak, four or five times its own length.

S. *acuta.* Sharp-mouthed Sphæria. Perſ. n. 122. Obſ. Mycol. faſc. 2. 70. Sowerb. Fung. t. 119.—Scattered, naked, black, ſhining, depreſſed, with a cylindrical ſharp beak.—Found on the dead ſtalks of nettles more eſpecially, in the ſpring. Firſt obſerved in England by the Rev. Mr. Relhan. It grows in a rather ſcattered manner; each plant like a minute bottle, vertically flattened.

S. *Peziza.* Scarlet-cup Sphæria. Perſ. n. 129. Tode Mecklenb. v. 2. 46. t. 15. f. 122. (S. miniata; Hoffm. Germ. v. 2. t. 12. f. 1. Peziza hydrophora; Bulliard t. 410. f. 2. Lycoperdon hydrophorum; Sowerb. Fung. t. 23.)—Crowded, dull red, globoſe, ſomewhat hairy; at length depreſſed and concave.—Frequent in the hollows of rotten trees in autumn, compoſing broad patches, of a dull ſcarlet hue. Each plant is ſmaller than a muſtard-ſeed, externally roughiſh or hairy. If Mr. Sowerby be right, the *ſeeds* appear to form a white ball, which is protruded out of the *capſule*, after which the latter becomes depreſſed and hollow, as all authors deſcribe it when advanced. See ſomewhat ſimilar in the character of SPHÆROBOLUS in its proper place.

S. *hiſpida.* Briſtly Sphæria. Perſ. n. 144. Tode Mecklenb. v. 2. 17. t. 10. f. 84.—Simple, ſcattered, pear-ſhaped, black, clothed with ſcattered ſpreading briſtles.—Found by Tode on oak branches, ſtripped of their bark, in September. Each individual is about half a line long, erect, ovate, tapering into a ſhort thick mouth; the outſide beſet with ſpreading briſtles, which well mark the ſpecies.

S. *herbarum*. Flat Common Sphæria. Perſ. n. 153. (S. complanata; Tode Mecklenb. v. 2. 21. t. 11. f. 88.)—Simple, ſcattered, orbicular, more or leſs depreſſed, ſmooth, brown, with a nipple-ſhaped mouth.—Copious on the dried ſtalks of various herbaceous plants. Each ſpecimen is about the ſize of the ſmalleſt pin's head. See *S. Saturnus*, Sowerb. Fung. t. 218.

S. *moriformis*. Mulberry-ſhaped Sphæria. Perſ. n. 168. Tode Mecklenb. v. 2. 22. t. 11. f. 90, 91.—Simple, ſcattered, elliptical or roundiſh, cloſed, tuberculated, black.—Said to be not unfrequent on dead branches, eſpecially of firs. This, like all the following, belongs to a tribe of ſpecies deſtitute of a beak, or any perceptible orifice. Its ſize is about equal to muſtard-ſeed. The whole ſurface is tuberculated. The ſhape elliptical, or globular. Perhaps this may be *S. claviformis*, Sowerb. Fung. t. 337.

S. *comata*. Tufted Sphæria. Perſ. n. 170. Tode Mecklenb. v. 2. 15. t. 10. f. 81.—Simple, crowded, globoſe, crowned with a converging tuft of capillary fibres, twice its own length.—Obſerved by Tode on the dead ſtems and ſtalks of plants after rain. This is a very remarkable ſpecies, on account of the denſe tuft of fibres, invariably found to crown the ſummit of each ſpecimen, and which, therefore, has no appearance of being of an extraneous or paraſitical nature. Indeed there are inſtances of briſtles or hairs, either generally or partially clothing ſome other ſpecies. The general colour is black, but a brown variety has been noticed, though rarely, on rotten wood of willows.

S. *cylindrica*. Cylindrical Ball-bearing Sphæria. Perſ. n. 180. Tode Mecklenb. v. 2. 42. t. 15. f. 114.—Simple, ſcattered, cylindrical, black, bearing a globe of white ſeeds.—Found by Tode on rotten willows, protruding from the wood in the form of minute, ſcattered, black points, hardly viſible to a caſual obſerver, each crowned by a little white ball of *ſeeds*, which betrays ſome analogy to that of *S. Peziza;* inſomuch that one might almoſt think ſuch a character, if well aſcertained in ſome other ſpecies, might form a generic diſtinction. We know, however, too little of the different changes, which the fructification of many of the reſt undergo, to draw a line between them, and theſe powdery balls, being doubtleſs liquid in an early ſtate, come under the eſſential definition of *Sphæria*. The character of *Næmaſpora* of authors, conſiſting in the permanently gelatinous nature of what its capſules diſcharge, ſeems to keep that genus ſufficiently diſtinct from the preſent.

SPHÆRISTERIUM, σφαιριστηριον, in *Antiquity*, the ſeventh part of the ancient gymnaſium; being that in which the youth practiſed tennis-playing.

The ſphæriſterium, or tennis-court, was between the place named *palæſtra*, and that where they ran races, which was between the porticoes and the outer wall, though Vitruvius does not make mention of it in the deſcription he gives of the ancient gymnaſium.

The exerciſe here performed was called σφαιριστικη, *ſphæriſtica*, and σφαιρομαχια, *ſphæromachia*, which ſome will have to have differed from the modern tennis; but it is not known in what the difference conſiſted.

The Mileſians were particularly averſe from this exerciſe; and the Athenians were as remarkably fond of it. Theſe latter frequently gave the freedom of their city to the ſphæriſtæ, or maſters in this art, by way of compliment.

SPHÆROBOLUS, in *Botany*, ſo named by Tode, from σφαιρα, *a globe*, and βολος, *a caſt*, or *throw;* becauſe the ſeeds are forcibly ejected, in the form of a little round ball.—Tode Mecklenb. v. 1. 43. Perſ. Syn. 115. (Carpobolus; Mich. Gen. 221. t. 101. Willd. Berol. 414.)—Claſs and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi, angiocarpi*.

Eſſ. Ch. Receptacle nearly globoſe, at length ſplitting into rays, and diſcharging elaſtically the globoſe ſeed-veſſel.

1. S. *ſtellatus*. Starry Projectile Puff-ball. Perſ. n. 1. (Lycoperdon Carpobolus; Linn. Sp. Pl. 1654. Hudſ. 644. Sowerb. Fung. t. 22.)—Found in various parts of Europe, in autumn, upon rotten wood or branches of trees, heaps of ſaw-duſt, or in the tan-pits of hot-houſes. In an early ſtate each plant conſiſts of a pale yellow globe, larger than a muſtard-ſeed. Several ſuch grow crowded together in patches, bound down, as it were, with a fine cottony web. After a while, each plant burſts into ſeveral ſtarry rays, and, by a momentary exploſion, projects, to the diſtance of ſix or eight inches, a whitiſh globular maſs of powdery *ſeeds* from its internal cavity. Sometimes this ball of *ſeeds* remains ſticking to the points of the rays. When fallen to a diſtance, the ſkin of the ball is found empty, the *ſeeds* having flown out in its paſſage through a hole at the baſe, which is uſually bordered by an inner layer of the outer ſtarry caſe, or *volva*, torn away by the ball.

We do not perceive the neceſſity of changing the original generic name, given by Micheli, whoſe figures and deſcription of this curious little fungus long excited the curioſity of botaniſts, before the plant was known to be ſo frequent as it is. Mr. Sowerby gives the beſt repreſentation of it. Tode deſcribes a ſecond ſpecies, which can ſcarcely belong to the ſame genus, and which is figured under the name of *Peziza marginata*, in Sowerby's Fungi, t. 16, and under that of *Patellaria excavata*, in Hoffmann's Plantæ Lichenoſæ, t. 23. t. 3. Albertini and Schweiniz mention this production with doubt, in their learned work on the Niſkian Fungi, p. 346. n. 1034; but it ſeems not as yet well underſtood.

SPHÆROCARPUS, ſo named by Micheli, from σφαιρα, *a globe*, and καρπος, *fruit*, in alluſion to its ſpherical ſeed-veſſel.—Mich. Gen. 4. Sm. Engl. Bot. v. 5. 299. Relh. 441. Mart. Mill. Dict. v. 4.—Claſs and order, *Cryptogamia Algæ?* or perhaps *Hepaticæ?* Nat. Ord. *Hepaticæ?*

Eſſ. Ch. Calyx inferior, of one leaf, inflated, entire. Seeds very numerous, collected into a globe, at the bottom of the calyx.

1. S. *terreſtris*. Reticulated Sphærocarpus. Engl. Bot. t. 299. (S. terreſtris, minima; Mich. Gen. 4. t. 3. Dill. Muſc. 536. t. 78. f. 17. Targionia Sphærocarpus; Dickſ. Crypt. faſc. 1. 8. With. v. 3. 814.)—Micheli firſt obſerved this ſingular little plant in gardens about Florence, in the winter and ſpring, growing in patches on the ground. The Rev. H. Bryant, Mr. Crowe, and Mr. Woodward, found it, ſince the publication of Hudſon's 2d edition, chiefly in the clover and turnip fields of Norfolk, eſpecially on ſtrong land, covering the earth copiouſly in the winter months, in patches of a pale glaucous green. The whole habit is delicate and membranous. *Fronds* ſimple, roundiſh or ovate, crowded, wavy, each attached by a fibrous, probably annual, *root*. The diſk of each frond is nearly covered by an aſſemblage of pear-ſhaped, reticulated, pellucid, bottle-like *calyces*, each a line long, contracted at the mouth, and lodging a little ball of green *ſeeds* at the bottom of its cavity, clothed with a fine ſkin. This plant ſeems to us eſſentially diſtinct in genus from TARGIONIA, (ſee that article,) and more allied to *Blaſia* and *Jungermannia*.

Sphærocarpus is alſo applied by ſome authors to deſignate a genus of *Fungi*, the Trichia of others. See that article.

Sphærocarpus of Gmelin, in his faulty edition of Linn. Syſt. Nat., is a ſcitamineous genus, the *Hura* of Koenig, now conſidered as a *Globba*.

SPHÆROLOBIUM, was ſo named by the writer of this article, from σφαιρα, *a globe*, and λοβιον, *the diminutive of* λοβος, *a pod*, to expreſs the roundiſh form of its very ſmall legume.—Sm. in Sims and Konig's Ann. of Bot. v. 1. 509. Brown in Ait. Hort. Kew. v. 3. 13.—Claſs and order, *Decandria Monogynia*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, permanent, bell-ſhaped, two-lipped; tube angular; upper lip in two abrupt oblique ſegments, united about half way up; lower in three deep, lanceolate, equal ones; without any lateral appendages. *Cor.* Papilionaceous, of five petals, with claws which are ſhorter than the calyx; ſtandard kidney-ſhaped, emarginate, aſcending; wings two, half obovate, rather ſhorter than the ſtandard, converging at the upper margin; keel equal to the wings, of two oblong cohering petals. *Stam.* Filaments ten, linear-awl-ſhaped, ſeparate, declining, ſhorter than the keel, the two uppermoſt with a ſpace between them; anthers roundiſh, two-lobed. *Piſt.* Germen ſtalked, roundiſh; ſtyle linear, keeled, rigid, obliquely rolled inward, about equal to the keel; ſtigma ſmooth, with a membranous dilatation at each ſide. *Peric.* on a ſtalk half its own length, obliquely orbicular, turgid, pointed, of one cell and two coriaceous valves. *Seeds* one or two, kidney-ſhaped.

Eſſ. Ch. Calyx five-cleft, two-lipped. Corolla papilionaceous. Stigma keeled, with a membranous border. Legume ſtalked, ſpherical, turgid, oblique. Two upper ſtamens diſtant.

1. S. *vimineum.* Yellow-flowered Sphærolobium. Sm. Tr. of Linn. Soc. v. 9. 261. Sims in Curt. Mag. t. 969. Ait. n. 1.—"Tube of the calyx rather ſhorter than the lips. Style curved from the very baſe, included in the keel." *Brown.*—Native of New Holland and Van Diemen's iſland. Our ſpecimens were originally ſent, in 1793, from Port Jackſon by Dr. White. Sir Joſeph Banks is ſaid to have introduced the plant at Kew in 1802. It flowers during ſummer, requiring the ſhelter of a greenhouſe in winter. The *ſtem* is erect, ſhrubby, branched, round, ſmooth, moſtly naked, the youngeſt branches only bearing a few ſcattered, ſmall, lanceolate *leaves*. *Flowers* numerous, in long ſtraight cluſters, rather ſmall. *Calyx* ſmooth, a little glaucous. *Corolla* yellow, the diſk of the *ſtandard* marked with a tranſverſe row of red dots. *Legume* the ſize of a vetch-ſeed.

2. S. *medium.* Small Red-flowered Sphærolobium. Ait. n. 2.—"Tube of the calyx half the length of the lips. Corolla red." *Brown.*—Obſerved by Mr. Brown, on the ſouth-weſt coaſt of New Holland, from whence it was ſent to Kew, by Mr. Peter Good, in 1803. We know nothing of this plant, except the above particulars, borrowed from the *Hortus Kewenſis*. The name ſeems to imply the exiſtence of a third ſpecies, of which we have no account.

SPHÆROMACHIA, σφαιρομαχια, in *Antiquity*, a particular kind of boxing, in which the combatants had balls of ſtone or lead in their hands, which were called σφαιραι.

SPHÆROPHORON, in *Botany*, from σφαιρα, *a globe*, and φερω, *to bear*, becauſe of the globular fructification.—Ach. Meth. 134. Lichenogr. 116. t. 12. f. 5, 6. Syn. 286. (Sphærophorus; Perſ. in Uſt. Annal. faſc. 7. 23.)—Claſs and order, *Cryptogamia Algæ*. Nat. Ord. *Algæ*, *Lichenes*.

Eſſ. Ch. *Receptacle* nearly globular, without a border, cartilaginous, with a torn orifice. *Seeds* compoſing a black powdery ball.

This moſt elegant genus of the natural family of Lichens, is at once known by its branched, buſhy, ſmooth habit, like that of a coral or coralline. Three ſpecies are known.

1. S. *coralloides.* Coral-branched Globe-Lichen. Ach. Syn. n. 1. (Lichen globiferus; Linn. Mant. 133. Engl. Bot. t. 115. L. fruticoſus coralloides, non tubuloſus, cinereus ramoſiſſimus, receptaculis florum ſphæricis concoloribus; Mich. Gen. 103. t. 39. f. 6. Coralloides cupreſſiforme, capitulis globoſis; Dill. Muſc. 117. t. 17. f. 35. C. globiferum; Hoffm. Pl. Lich. v. 2. 25. t. 31. f. 2.)—Stem pale brown, cylindrical; its lateral branches elongated, divaricated, forked, with ſlender white tips. Receptacles globoſe, ſmooth.—Native of mountainous rocky heaths, and fir woods, in the cooler parts of Europe. Abundant in Scotland, Wales, Derbyſhire, &c. The ſmooth poliſhed browniſh *ſtems* compoſe lax tufts, an inch or two high, ſoft and pliant when wet, very brittle when dry, reſembling little groves of coral. The flowering *ſtems* are ſtouter, more ſimple, and rather taller than the reſt, their ſtrongeſt branches each terminating in a ſmooth ball of their own ſubſtance and colour, ſmaller than a pea, opening by a torn mouth at the ſummit, and containing a denſe ball of very black powdery *ſeeds*.

2. S. *fragile.* Brittle Globe-Lichen. Ach. Syn. n. 2. Meth. 135. t. 3. f. 5. Engl. Bot. t. 2474. (Lichen fragilis; Linn. Fl. Suec. ed. 2. 425. Fl. Lap. ed. 2. 351. t. 11. f. 4. Ehrh. Crypt. 128. Coralloides fragile; Hoffm. Pl. Lich. v. 2. 34. t. 33. f. 3.)—Stem greyiſh; its branches crowded, forked, round. Receptacles obovate, rugoſe. Native of moſſy rocks and mountains in the north of Europe. We have found it on the Pentland hills, near Edinburgh, but without fructification. In this ſtate it forms broad patches of denſe, pale grey, branching *ſtems*, whoſe branches are round, ſomewhat annular, obtuſe, level-topped. In ſome German and Swediſh ſpecimens, larger and ſtouter branches bear obovate or pear-ſhaped *receptacles*, or *ſeed-veſſels*, of a dark brown, whoſe ſurface is cracked or corrugated, their ſize about equal to the preceding.

3. S. *compreſſum.* Compreſſed Globe-Lichen. Ach. n. 3. (Lichen fragilis; Linn. Sp. Pl. 1621. Jacq. Miſc. v. 2. 92. t. 9. f. 6, c. Engl. Bot. t. 114. L. melanocarpus; Swartz Prodr. 147. Coralloides alpinum, corallinæ minoris facie; Dill. Muſc. 116. t. 17. f. 34.)—Stem white; its branches compreſſed. Receptacles ſomewhat lateral, depreſſed, ſmooth.—Found in moiſt places, under the ſhade of rocks, on the mountains of Germany, Switzerland, and England, as well as in the Weſt Indies, and at the Cape of Good Hope. This beautiful ſpecies, in the poliſhed white of its ſurface, and its flat palmate ramifications, exceeds the elegance of the foregoing, and ſtill more reſembles a coralline. The height of the branching fan-like *ſtem* is two or three inches, and the fructification, when preſent, is copious, uſually turned to one ſide, flattened, often bordered with granulations or ſhoots; the powder intenſely black, mixed with fibres of the ſame colour.—In the account given in Engliſh Botany, the idea of the laſt ſpecies, in a barren ſtate, was comprehended under this.

SPHAGITIDES, a name given by ſome authors to the jugular veins.

SPHAGNUM, in *Botany*, a name uſed by Pliny for ſome ſort of moſs that grows upon trees, adopted by Dillenius and Linnæus, for the genus now called Bog-moſs.—Dill. Muſc. 240. Linn. Gen. 562. Schreb. 758. Mart. Mill. Dict. v. 4. Hedw. Fund. v. 2. 85. Theor. t. 12. Sp. Muſc. 27. Sm. Fl. Brit. 1145. Juſſ. 12. Lamarck Illuſtr. t. 872.—Claſs and order, *Cryptogamia Muſci.* Nat. Ord. *Muſci.*

Eſſ. Ch. Capſule ſeſſile, without a fringe. Veil cut round, its baſe remaining on the baſe of the capſule. Anthers each ſurrounded with a ring.

Obſ. Weber and Mohr have juſtly remarked, that this is the only known genus of moſſes in which the germen and capſule are truly ſeſſile, not at any ſtage of growth elevated on a *pedicellus*, or partial ſtalk, above the baſe of the flower. The whole flower indeed, and conſequently the ripe capſule, is ſtalked, which being rarely the caſe with other moſſes, whoſe *pedicelli* are very long, the two different kinds of ſtalk have been confounded together.

1. S. *latifolium.* Broad-leaved Bog-moſs. Hedw. Sp. Muſc. 27. Fl. Brit. n. 1. Engl. Bot. t. 1405. Turn. Muſc. Hib. 5. (S. paluſtre α; Linn. Sp. Pl. 1569. Fl. Dan. t. 474. S. paluſtre molle deflexum, ſquamis cymbiformibus; Dill. Muſc. 240. t. 32. f. 1.)—Branches tumid, deflexed. Leaves ovate, obtuſe, concave. This moſs occupies the ſurface of watery turfy bogs throughout Europe, bearing capſules in ſummer. Its pale whitiſh-green hue, often tinged with red, makes the plant conſpicuous. The large maſſes it compoſes are moſtly filled with water, like a ſponge, and are not firm enough to be walked upon. *Droſeræ*, *Erica tetralix*, and the Cranberry, are the chief plants that grow amongſt it, often without being rooted in the ground. The *ſtems* are various in height, ſoft and flexible, beſet with numerous, ſhort, tumid, tapering branches, ſlightly bent downward; the uppermoſt crowded. *Leaves* imbricated, pellucid, broad, obtuſe, entire, incurved, reticulated, without rib or veins. *Capſules* about the tops of the ſtems, erect, brown, ſmooth, on flower-ſtalks not an inch long. *Lid* almoſt flat. *Veil* thin, more or leſs of its circular baſe remaining round the capſule. The ſoftneſs and elaſticity of this moſs render it very fit for packing.

2. S. *ſquarroſum.* Prominent-leaved Bog-moſs. Mohr Ind. 2. Sm. Compend. ed. 2. 159. Engl. Bot. t. 1498.—Branches deflexed, tapering. Leaves ovate, acute, with recurved, prominent, keeled points.—Native of Germany, Sweden, and England. Mr. Turner gathered this ſpecies, which the late Mr. Mohr only had previouſly mentioned, not deſcribed, on bogs at Belton, near Yarmouth, bearing fruit in June and July. It differs from the foregoing in the more taper terminations of the *branches*, and eſpecially in the ſpreading recurved points of its *leaves*, which have a central fold like a keel, and give the ſquarroſe character of the plant. The *capſules* have a prominent beaked lid.

3. S. *capillifolium.* Slender Bog-moſs. Hedw. Sp. Muſc. 28. Fl. Brit. n. 2. Engl. Bot. t. 1406. Turn. Muſc. Hib. 6. (S. paluſtre β; Linn. Sp. Pl. 1569. S. paluſtre molle deflexum, ſquamis capillaceis; Dill. Muſc. 243. t. 32. f. 2, A.)—Branches ſlender, deflexed. Leaves ovato-lanceolate, pointed, flattiſh, cloſe-preſſed, with ſtraight points.—Abundant on bogs, eſpecially in rather mountainous ſituations, bearing capſules in ſummer, and often tinged with red. Its much ſmaller ſize, and narrower flatter *leaves*, diſtinguiſh this from both the preceding. The reticulations of the foliage are obſerved by Mr. I. D. Sowerby to be peculiar, the little tranſverſe veins running in pairs. Sometimes a fold, or keel, reſembling a mid-rib, is diſcernible.

4. S. *cuſpidatum.* Long-leaved Floating Bog-moſs. Hoffm. Germ. v. 2. 22. Fl. Brit. n. 3. Engl. Bot. t. 2092. Ehrh. Crypt. 251. Turn. Muſc. Hib. 6. (S. paluſtris mollis deflexi, ſquamis capillaceis, varietas fluitans; Dill. Muſc. 244. t. 32. f. 2, B.)—Branches ſpreading, rather downwards. Leaves lanceolate, long-pointed, wavy, lax.—Moſt frequent, in pools or rivulets, among bogs in mountainous countries, but Mr. Turner found it near Yarmouth, bearing fruit in ſummer. This reſembles the common *latifolium* in colour, but the more elongated floating *ſtems*, diſtinguiſh the ſpecies before us. The *branches* are looſely directed downward, pointed, often very ſlender. The reticulations of the *leaves* moſt accord with thoſe of our laſt ſpecies; but their points are more elongated, and edges wavy. *Capſule* ſhort, and rather bell-ſhaped when fully ripe.

We have thus brought together four ſpecies of the preſent genus. Hedwig has but two, beſides the *S. alpinum* of Linnæus, figured in Dillenius, t. 32. f. 3, which is founded in an error of the laſt-mentioned author. What he deſcribed and delineated, prove to be nothing more than luxuriant bog ſpecimens of *Dicranum flexuoſum* of Hedwig and Fl. Brit., Engl. Bot. t. 1491, among which ſome extraneous bodies had fallen, and theſe were miſtaken for capſules.

SPHENE, in *Mineralogy*, a mineral compoſed of nearly equal parts of oxyd of titanium, ſilex, and lime. Its colours are generally a dark brown, inclining to red or yellow. It occurs cryſtallized in various forms, and alſo ſometimes in maſſes. The cryſtals are more frequently four-ſided priſms, either oblique or rectangular, or ſix-ſided priſms, with two oppoſite ſides broader than the reſt, or elongated octohedrons. The edges of the cryſtals are frequently bevelled, and the apices of the octohedrons are ſometimes ſo flattened as to preſent a lenticular form.

The fracture of ſphene is imperfectly conchoidal; it ſcratches glaſs, and is brittle. The internal luſtre is ſhining, inclining to reſinous. The ſpecific gravity is from 3.480 to 3.510. It is fuſible by the blowpipe into a blackiſh-brown enamel. This mineral is found imbedded in ſienite and granite in various parts of Scotland, and alſo in Sweden, Norway, France, Switzerland, and in North America. The name ſphene was given to this mineral by Haüy, from the wedge-like ſhape of ſome of the cryſtals.

Foliated ſphene differs from the above in colour, which is various ſhades of yellow, inclining to a ſtraw or cream colour, and in the ſtructure, which is foliated, with a double cleavage parallel to the ſide of an oblique four-ſided priſm. The croſs fracture is foliated. Both theſe varieties of ſphene paſs from different degrees of tranſlucency to opacity.

SPHENOCLEA, in *Botany*, ſo denominated by Gærtner, from σφην, *a wedge*, and κλειω, *to ſhut up*, becauſe of the wedge-ſhaped ſeed-veſſel.—Gærtn. v. 1. 113. t. 24. f. 5. Willd. Sp. Pl. v. 1. 927. (Gærtnera; Retz. Obſ. faſc. 6. 24. Rapinia; Loureir. Cochinch. 127. Pongatium; Juſſ. 423.)—Claſs and order, *Pentandria Monogynia.* Nat. Ord. *Lyſimachiæ*, Juſſ.?

Gen. Ch. *Cal.* Perianth ſuperior, of five roundiſh, permanent leaves, broad at the baſe. *Cor.* of one petal, ſhorter than the calyx; tube very ſhort; limb in five lanceolate, equal, erect ſegments. *Stam.* Filaments five, capillary, very ſhort, inſerted into the tube of the corolla; anthers roundiſh, two-lobed. *Piſt.* Germen inferior, compreſſed at the baſe; ſtyle very ſhort; ſtigma capitate, permanent.

manent. *Peric.* Capſule compreſſed, wedge-ſhaped, quadrangular, obtuſe, of two cells, burſting all round near the top. *Seeds* very numerous, minute, oblong, affixed to a pendulous receptacle in each cell.

Eſſ. Ch. Corolla five-cleft, ſmaller than the calyx. Capſule compreſſed, of two cells, burſting all round. Seeds numerous. Receptacles curved downwards. Stigma capitate, permanent.

1. S. *zeylanica.* Willd. n. 1. (Pongati; Rheede Hort. Malab. v. 11. 47. t. 24.)—Native of moiſt ſituations in the Eaſt Indies, Cochinchina, Ceylon and Guinea. The *root* is fibrous and annual. *Stem* erect, one or two feet high, ſimple or branched, leafy. *Leaves* ſcattered, ſtalked, lanceolate, entire, ſmooth, ſomewhat fleſhy, about two inches long, of a pale rather glaucous green. *Flowers* greeniſh-white, in denſe, terminal, erect, cylindrical ſpikes, of no beauty, nor do we know that the plant has any valuable properties. Its general aſpect is that of ſome kind of *Reſeda,* particularly the *R. Luteola.* It was originally choſen by ſir Joſeph Banks to commemorate the eminent botanical merits of Gærtner, for which the ſtriking peculiarities of its ſeed-veſſel made it very eligible; but there is now another GÆRTNERA, of equal ſingularity and more beauty. See that article.

SPHENOGYNE, apparently from σφην, *a wedge,* and γυνη, *a female,* in alluſion to the wedge-ſhaped ſtigmas.—Brown in Ait. Hort. Kew. v. 5. 142.—Claſs and order, *Syngeneſia Polygamia-fruſtranea.* Nat. Ord. *Compoſitæ diſcoideæ,* Linn. *Corymbiferæ,* Juſſ.

Gen. Ch. *Common Calyx* roundiſh, imbricated; its ſcales rounded or awl-ſhaped, concave, with a membranous dilated border, moſt conſpicuous on the inner ones. *Cor.* compound, radiated; florets of the diſk numerous, funnel-ſhaped, five-cleft, equal, all perfect; thoſe of the radius about twenty, ligulate, longer than the diameter of the diſk, toothed at the end imperfectly, female. *Stam.* in the florets of the diſk, filaments five, capillary, ſhort; anthers united into a tube, nearly as long as the corolla. *Piſt.* Germen ſcarcely diſcernible in the florets of the radius; in thoſe of the diſk oblong, quadrangular; ſtyle thread-ſhaped in both; ſtigmas in the florets of the radius obſolete; in thoſe of the diſk dilated upwards, rather abrupt at the ſummit. *Peric.* none, except the permanent dry calyx. *Seeds* in the diſk only, angular. Down of five rounded, membranous, horizontal ſcales. *Recept.* chaffy, flattiſh.

Eſſ. Ch. Scales of the receptacle diſtinct. Seed-down of five ſimple membranous leaves. Stigma dilated upwards, abrupt. Calyx imbricated; its inner ſcales with a membranous border.

1. S. *anthemoides.* White-crowned Sphenogyne. Ait. n. 1. (Arctotis anthemoides; Linn. Sp. Pl. 1307. Willd. Sp. Pl. v. 3. 2361. Curt. Mag. t. 544. Chamæmelum pumilum, foliis anguſtis pinnatis; Burm. Afr. 174. t. 63. f. 2.)—Herbaceous, ſmooth. Leaves ſimply or doubly pinnatifid, linear-thread-ſhaped. Seed-down white, with brown awl-ſhaped ribs.—A native of the Cape of Good Hope, which proves a hardy annual in our gardens, flowering from July to September. Mr. Maſſon introduced it in 1774. The *root* is fibrous. *Stem* branched. *Leaves* ſomewhat like chamomile. *Flowers* terminal, ſolitary, ſtalked, an inch and half or more in diameter; yellow above; their rays purple underneath. The pure white chaffy *ſeed-crown,* radiated with brown, forms the moſt ſtriking part of the plant, and may be preſerved with everlaſting flowers through winter.

2. S. *crithmifolia.* Samphire-leaved Sphenogyne. Ait. n. 2. (Arctotis paleacea; Linn. Sp. Pl. 1307. Willd. Sp. Pl. v. 3. 2359. Aſter foliis integris anguſtis, flore magno luteo; Burm. Afr. 176. t. 65. f. 1.)—Shrubby, ſmooth. Leaves pinnatifid, linear-thread-ſhaped. Outer ſcales of the calyx awl-ſhaped.—Native of the Cape of Good Hope. A greenhouſe ſhrub, cultivated by Miller, flowering throughout the ſummer. The *ſtem* is buſhy. *Flowers* large, yellow. Inner ſcales of the calyx very broad and rounded, while the outer are awl-ſhaped, and ſcarcely membranous.

3. S. *ſcarioſa.* Scaly-cupped Sphenogyne. Ait. n. 3. (Arctotis ſcarioſa; Ait. ed. 1. v. 3. 274. Willd. Sp. Pl. v. 3. 2360.)—"Leaves ſimply or doubly pinnatifid, linear-thread-ſhaped, ſmooth. All the ſcales of the calyx membranous, obtuſe, ſhining; the outermoſt ſeſſile."—Sent by Mr. Maſſon from the Cape in 1774. A greenhouſe ſhrub, flowering from April to Auguſt. Differs from the laſt in having all its *calyx-ſcales* dilated and membranous.

4. S. *abrotanifolia.* Southernwood-leaved Sphenogyne. Brown MSS. Ait. n. 4.—"Shrubby. Leaves twice or thrice pinnatifid, downy as well as the calyx."—A greenhouſe ſhrub, ſent by Mr. Maſſon from the Cape in 1789, and flowering all ſummer long.

5. S. *dentata.* Small-leaved Sphenogyne. Ait. n. 5. (Arctotis dentata; Linn. Sp. Pl. 1307. Willd. Sp. Pl. v. 5. 2359. Chryſanthemum foliorum pinnis breviſſimis, dentatis; Burm. Afr. 175. t. 64.)—Shrubby. Leaves pinnatifid, nearly ſmooth; each ſegment with two or three divaricated hair-pointed teeth. Outer ſcales of the calyx ovato-lanceolate.—From the ſame country. A greenhouſe ſhrub, flowering in June and July, introduced in 1787, by Mr. John Hunnemann. The *leaves* are copious, ſhort, and criſped. *Flowers* hardly an inch broad, yellow. Points of the *calyx-ſcales* downy; the inner ones bearing a very thin, pellucid, orbicular appendage.

6. S. *odorata.* Smooth-ſeeded Sphenogyne. Ait. n. 6. (Anthemis odorata; Ait. ed. 1. v. 3. 238. Willd. Sp. Pl. v. 3. 2186.)—"Shrubby. Leaves flat, ſmooth; cut or pinnatifid at the extremity. Outer calyx-ſcales membranous at the point. Seeds ſmooth, with a ſlight crown."—Sent by Mr. Maſſon from the Cape in 1774. A greenhouſe ſhrub, flowering from April to June. The *branches* are downy. *Leaves* ſmall, half an inch long. *Flowers* on very long, almoſt naked, ſtalks.

SPHENOID, in *Anatomy,* one of the bones of the head. See CRANIUM.

SPHENO-MAXILLARY FISSURE, a large interval, in the lower and outer part of the orbit, between the ſphenoid and upper jaw-bones. See CRANIUM.

SPHENO-PALATINE FORAMEN, an opening between the ſphenoid and palate bones, leading into the noſe. The ſame epithet is alſo given to certain nerves which go through that opening, and to the levator palati muſcle.

SPHENO-PHARYNGEUS, a name applied to a part of the conſtrictor pharyngis ſuperior muſcle. See DEGLUTITION.

SPHENO-PTERYGO-PALATINUS, a name given by Cowper to the circumflexus palati muſcle. See DEGLUTITION.

SPHENO-SALPINGO-PHARYNGEUS, a ſmall portion of the ſuperior conſtrictor of the pharynx, deſcribed under this name by Winſlow.

SPHENO-SALPINGO-STAPHYLINUS, a name given by Winſlow to a portion of the circumflexus palati.

SPHENO-STAPHYLINUS, the levator palati mollis, according to Drake and Cowper.

SPHERE, SPHÆRA, σφαιρα, in *Geometry,* a ſolid body contained under one ſingle ſurface, and having a point in the middle, called the *centre,* whence all lines, drawn to the ſurface, are equal.

The ſphere is ſuppoſed to be generated by the revolution of a ſemicircle A B C (*Plate* XIV. *Geometry, fig.* 2.) about its diameter A C, which is alſo called the *axis of the ſphere;* and the extreme points of the axis, A and C, are called the *poles of the ſphere.*

SPHERE, *Properties of the.* 1. A ſphere is equal to a pyramid, whoſe baſe is equal to the ſurface, and its height to the radius of the ſphere.

Hence, a ſphere being eſteemed ſuch a pyramid, its cube, or ſolid content, is found like that of a pyramid.

2. A ſphere is to a cylinder, ſtanding on an equal baſis, and of the ſame height, as 2 to 3. Hence, alſo, may the cube, or content of the ſphere, be found.

3. A ſphere is equal to four times the cone, the baſe of which is equal to the generating circle, and the height of which is equal to the radius. Or, a hemiſphere is equal to twice the cone of the ſame baſe and height. And a cylinder, of the ſame height and baſe, being a triple of the cone, it follows, that the hemiſphere is two-thirds of the cylinder, and conſequently the whole ſphere two-thirds of the circumſcribing cylinder. Archim. de Sph. et Cycl. Apud Opera per Rivaltum, p. 67.

4. The cube of the diameter of a ſphere is to the ſolid content of the ſphere, nearly as 300 to 157: and thus, alſo, may the content of the ſphere be meaſured.

5. The ſurface of a ſphere is quadruple the area of a circle deſcribed with the radius of the ſphere. For ſince a ſphere is equal to a pyramid, whoſe baſe is the ſurface, and its altitude the radius of the ſphere; the ſurface of the ſphere is had, by dividing its ſolidity by a third part of its ſemi-diameter, or one-ſixth of the whole diameter.

But the ſolidity of the ſphere is the product of $\frac{2}{3}$ds of the greateſt circle by the diameter; and if this product be divided by $\frac{1}{6}$th of the diameter, the quotient, or $\frac{12}{3}$ of the greateſt circle, *i. e.* four times the greateſt circle, will be the ſurface of the ſphere.

Otherwiſe: the ſurface of a ſphere is equal to the product of its diameter, and the periphery of its generating circle; but the area of this circle is equal to the product of the ſemi-diameter and half the periphery, or one-fourth of the product of the diameter and periphery; and, therefore, the ſurface of the ſphere is equal to four times the area of its generating circle.

Hence, 6. The ſurfaces of ſpheres are to one another as the ſquares of their diameters; becauſe theſe ſurfaces, being four times their generating circles, are as theſe circles, *i. e.* as the ſquares of their diameters.

7. Spheres being $\frac{2}{3}$d parts of cylinders of equal baſe and altitude, and cylinders being as the cubes of their altitudes, are as the cubes, or in the triplicate ratio of their diameters.

8. The ſurface of any portion of a ſphere, greater or leſs than the hemiſphere, is equal to the area of a circle, whoſe radius is a line drawn from the vertex of that portion to the circumference of the circle which is its baſe. Archimedes, *ubi ſupra,* pp. 84, 85.

SPHERE, *the diameter of a, being given, to find its ſurface and ſolidity.* Find the periphery of the circle deſcribed by the radius of the ſphere, or of the generating circle.

Multiply this, found, into the diameter, or the ſquare of the diameter, by 3.1416, the product is the ſurface of the ſphere. Multiply the ſurface by a ſixth part of the diameter, or the area of the generating circle by $\frac{2}{3}$ds of its diameter; or, again (becauſe the area of ſuch circle is to the ſquare of the diameter as .7854 to 1), the cube of the diameter by .5236 ($= \frac{2}{3}$ of .7854); and the product is the ſolidity of the ſphere.

Thus, ſuppoſing the diameter of the ſphere 56, the periphery will be found 175.9, which multiplied by the diameter, the product 9852 is the ſurface of the ſphere; which multiplied by $\frac{1}{6}$th part of the diameter, gives the ſolidity 91623.6. Or thus:

Find the cube of the diameter 175616; then to 300,157, and the cube found, find a fourth proportional. This is the ſolidity of the ſphere required.

For finding the ſurface and ſolidity of the ſphere by the method of fluxions, ſee SUPERFICIES and SOLIDITY. For ſegments and ſectors of ſpheres, ſee FRUSTUM, SEGMENT, and SECTOR.

SPHERE, *Doctrine of the.* See SPHERICS.

SPHERE, *Projection of the.* See PROJECTION.

SPHERE *of Activity.* See ACTIVITY.

SPHERE, in *Aſtronomy,* that concave orb or expanſe which inveſts our globe, and in which the heavenly bodies, *viz.* ſun, ſtars, planets, and comets, appear to be fixed at an equal diſtance from the eye.

This is alſo called the *ſphere of the world;* and is the ſubject of the ſpherical aſtronomy.

This ſphere, as it includes the fixed ſtars, whence we alſo occaſionally call it the *ſphere of the fixed ſtars,* is immenſely great. The diameter of the earth's orbit is ſo ſmall, in reſpect to the diameter of this, that the centre of the ſphere is not ſenſibly changed by any alteration of the ſpectator's place in the ſeveral parts of the orbit; but ſtill, in all the points of the earth's ſurface, and at all times, the inhabitants have the ſame appearance of the ſphere; that is, the fixed ſtars ſeem to poſſeſs the ſame points in the ſurface of the ſphere. For our way of judging of the places, &c. of the ſtars, is to conceive right lines drawn from the eye, or the centre of the earth, through the centre of the ſtars, and continued thence till they cut the foreſaid ſphere; the points where theſe lines terminate in it are the apparent places of thoſe ſtars.

The better to determine the places of the heavenly bodies in the ſphere, ſeveral circles are imagined to be deſcribed in the ſurface thereof, hence called *circles of the ſphere.*

SPHERE, in *Geography,* &c. denotes a certain diſpoſition of the circles on the ſurface of the earth, with regard to one another, which varies in various parts of it.

The circles originally conceived on the ſurface of the ſphere of the world, are almoſt all transferred, by analogy, to the ſurface of the earth, where they are conceived to be drawn directly underneath thoſe of the ſphere, or in the ſame planes with them; ſo that, if the planes of thoſe of the earth were continued to the ſphere, they would coincide with the reſpective circles upon it. Thus we have an horizon, meridian, equator, &c. on the earth.

As the equator in the heavens divides the ſphere into two equal parts, the one north, and the other ſouth, ſo does the equator on the ſurface of the earth divide the globe in the ſame manner.

And as the meridians in the heavens paſs through the poles of the horizon, ſo do thoſe of the earth, &c.

With regard, then, to the poſition of ſome of the circles in reſpect of others, we have a right, a parallel, and an oblique ſphere.

SPHERE, *Armillary,* or *Artificial,* is an aſtronomical inſtrument, repreſenting the ſeveral circles of the ſphere in their natural order; ſerving to give an idea of the office and poſition of each of them, and to ſolve various problems relating to them.

It is thus called, as conſiſting of a number of faſciæ or rings of braſs, or other matter, called by the Latins *armillæ*, from their reſemblance to bracelets, or rings for the arm.

By this it is diſtinguiſhed from the globe, which, though it hath all the circles of the ſphere on its ſurface; yet is not cut into armillæ or rings, to repreſent the circles ſimply and alone; but exhibits alſo the intermediate ſpaces between the circles.

Sphere, *The Armillary*, of Mr. Ferguſon, conſtructed after the model of the glaſs ſphere of Dr. Long, is repreſented *Plate* XX. *Aſtronomy*, *fig*. 5.

The exterior parts of this machine are a compages of braſs rings, which repreſent the principal circles of the heavens, *viz.* 1. The equinoctial A A, which is divided into 360 degrees (beginning at its interſection with the ecliptic in Aries), for ſhewing the ſun's right aſcenſion in degrees; and alſo into twenty-four hours, for ſhewing his right aſcenſion in time. 2. The ecliptic B B, which is divided into 12 ſigns, and each ſign into 30 degrees, and alſo into the months and days of the year, in ſuch a manner, that the degree or point of the ecliptic in which the ſun is, on any given day, ſtands over that day in the circle of months. 3. The tropic of Cancer C C, touching the ecliptic at the beginning of Cancer in *e*; and the tropic of Capricorn D D, touching the ecliptic at the beginning of Capricorn in *f*; each 23½ degrees from the equinoctial circle. 4. The arctic circle E, and the antarctic circle F, each 23½ degrees from its reſpective pole at N and S. 5. The equinoctial colure G G, paſſing through the north and ſouth poles of the heaven at N and S, and through the equinoctial points Aries and Libra, in the ecliptic. 6. The ſolſtitial colure H H, paſſing through the poles of the heaven, and through the ſolſtitial points Cancer and Capricorn, in the ecliptic. Each quarter of the former of theſe colures is divided into 90 degrees, from the equinoctial to the poles of the world, for ſhewing the declination of the ſun, moon, and ſtars: and each quarter of the latter, from the ecliptic at *e* and *f*, to its poles *b* and *d*, for ſhewing the latitudes of the ſtars.

In the north pole of the ecliptic is a nut *b*, to which is fixed one end of a quadrantal wire, and to the other end a ſmall ſun Y, which is carried round the ecliptic B B, by turning the nut: and in the ſouth pole of the ecliptic is a pin at *d*, on which is another quadrantal wire, with a ſmall moon, Z, upon it, which may be moved round by hand: but there is a particular contrivance for cauſing the moon to move in an orbit which croſſes the ecliptic at an angle of 5⅓ degrees, in two oppoſite points, called the *moon's nodes*; and alſo for ſhifting thoſe points backward in the ecliptic, as the moon's nodes ſhift in the heaven.

Within theſe circular rings is a ſmall terreſtrial globe I, fixt on an axis K K, which extends from the north and ſouth poles of the globe at *n* and *s*, to thoſe of the celeſtial ſphere at N and S. On this axis is fixt the flat celeſtial meridian L L, which may be ſet directly over the meridian of any place on the globe, and then turned round with the globe, ſo as to keep over the ſame meridian upon it. This flat meridian is graduated the ſame way as the braſs meridian of the common globe, and its uſe is much the ſame. To this globe is fitted the moveable horizon M M, ſo as to turn upon two ſtrong wires proceeding from its eaſt and weſt points to the globe, and entering the globe at oppoſite points of its equator, which is a moveable braſs ring let into the globe in a groove all round its equator. The globe may be turned by hand within this ring, ſo as to place any given meridian upon it, directly under the celeſtial meridian L L. The horizon is divided into 360 degrees all round its outermoſt edge, within which are the points of the compaſs, for ſhewing the amplitude of the ſun and moon, both in degrees and points. The celeſtial meridian L L paſſes through two notches in the north and ſouth points of the horizon, as in a common globe: but here, if the globe be turned round, the horizon and meridian turn with it. At the ſouth pole of the ſphere is a circle of 24 hours, fixt to the rings, and on the axis is an index which goes round that circle, if the globe be turned round its axis.

The whole fabric is ſupported on a pedeſtal N, and may be elevated or depreſſed upon the joint O, to any number of degrees from 0 to 90, by means of the arc P, which is fixed into the ſtrong braſs arm Q, and ſlides into the upright piece R, in which is a ſcrew at *r*, to fix it at any proper elevation.

In the box T are two wheels (as in Dr. Long's ſphere), and two pinions, whoſe axes come out at V and U; either of which may be turned by the ſmall winch W. When the winch is put upon the axis V, and turned backward, the terreſtrial globe, with its horizon and celeſtial meridian, keep at reſt; and the whole ſphere of circles turns round from eaſt, by ſouth, to weſt, carrying the ſun Y, and the moon Z, round the ſame way, and cauſing them to riſe above and ſet below the horizon. But when the winch is put upon the axis U, and turned forward, the ſphere with the ſun and moon keep at reſt; and the earth, with its horizon and meridian, turn round from weſt, by ſouth, to eaſt; and bring the ſame points of the horizon to the ſun and moon, to which theſe bodies came when the earth kept at reſt, and they were carried round it; ſhewing that they riſe and ſet in the ſame points of the horizon, and at the ſame times in the hour-circle, whether the motion be in the earth or in the heaven. If the earthly globe be turned, the hour-index goes round its hour-circle; but if the ſphere be turned, the hour-circle goes round below the index.

And ſo, by this conſtruction, the machine is equally fitted to ſhew either the real motion of the earth, or the apparent motion of the heaven.

To rectify the ſphere for uſe, firſt ſlacken the ſcrew *r* in the upright ſtem R, and taking hold of the arm Q, move it up or down until the given degree of latitude for any place be at the ſide of the ſtem R; and then the axis of the ſphere will be properly elevated, ſo as to ſtand parallel to the axis of the world, if the machine be ſet north and ſouth by a ſmall compaſs: this done, count the latitude from the north pole, upon the celeſtial meridian L L, down towards the north notch of the horizon, and ſet the horizon to that latitude; then turn the nut *b* until the ſun Y comes to the given day of the year in the ecliptic, and the ſun will be at its proper place for that day: find the place of the moon's aſcending node, and alſo the place of the moon, by an Ephemeris, and ſet them right accordingly: laſtly, turn the winch W, until either the ſun comes to the meridian L L, or until the meridian comes to the ſun (according as you want the ſphere or earth to move), and ſet the hour-index to the XII, marked noon, and the whole machine will be rectified. Then turn the winch, and obſerve when the ſun or moon riſe and ſet in the horizon, and the hour-index will ſhew the times of them for the given day. See Ferguſon's Lectures, p. 194, &c.

Armillary ſpheres are of different kinds with regard to the poſition of the earth in them; whence they become diſtinguiſhed into *Ptolemaic* and *Copernican* ſpheres: in the firſt of which the earth is in the centre, and in the latter near the circumference, according to the poſition which that planet obtains in thoſe ſyſtems.

Sphere, *The Ptolemaic*, is that commonly in uſe, and is repreſented (*Plate* XX. *Aſtronomy*, *fig*. 6.) with the names of the ſeveral circles, lines, &c. of the ſphere, inſcribed on them. In the middle, upon the axis of the ſphere, is a ball, T, repreſenting the earth, on whoſe ſurface are the circles, &c. of the earth. The ſphere is made to revolve about the ſaid axis, which remains at reſt; by which means the ſun's diurnal and annual courſe about the earth are repreſented according to the Ptolemaic hypotheſis; and even by means of it, all problems relating to the phenomena of the ſun and earth are ſolved, as upon the celeſtial globe, and after the ſame manner, which ſee deſcribed under Globe.

Sphere, *The Copernican*, (repreſented *Plate* XX. *Aſtronomy*, *fig.* 7.) is very different from the Ptolemaic, both in its conſtitution and uſe; and is more intricate in both. Indeed, the inſtrument is in the hands of ſo few people, and its uſe ſo inconſiderable, except what we have in the other more common inſtruments, particularly the globe and Ptolemaic ſphere, that we ſhall be eaſily excuſed the not taking up room with any deſcription of it.

Spheres, *Harmony of the.* See Harmony.

Spheres, *Obliquity of the.* See Obliquity.

Sphere, *Rectifying of the.* See Rectifying.

Sphere, *Dialling.* See Dialling.

Spheres, poliſhed ſpherical maſſes of a mixed metalline compoſition, uſed in optics. The manner of making them is as follows.

Take of pure tin, three pounds; copper, one pound; melt theſe two metals together, and when in fuſion caſt upon the maſs ſix ounces of burnt tartar, and an ounce and half of ſaltpetre; and laſtly, a quarter of an ounce of alum, and two ounces of arſenic: let all theſe matters evaporate and burn away, and then caſt the pure metal into the figure of a ſphere, and it will be capable of a high and elegant poliſh. Neri's Art of Glaſs, p. 166. See Steel-*Glaſſes*.

SPHERICAL Angle, is the mutual inclination of two planes, by which a ſphere is cut.

Thus, the inclination of the two planes C A F and C E F, (*Plate* II. *Trigonometry*, *fig.* 1.) forms the ſpherical angle A C E.

The meaſure of a ſpherical angle, A C E, is an arc of a great circle A E, deſcribed from the vertex C, as from a pole, and intercepted between the legs C A and C E.

Hence, 1. Since the inclination of the plane C E F to the plane C A F is every where the ſame, the angles in the oppoſite interſections, C and F, are equal.

2. Hence the meaſure of a ſpherical angle A C E is deſcribed by the interval of a quadrant A C or E C from the vertex C, between the legs C A, C E.

If a circle of the ſphere A E B F (*fig.* 2.) cut another, C E D F, the adjacent angles, A E C and A E D, are equal to two right ones; and the vertical angles, A E C and D E B, are equal to one another. The former likewiſe holds of ſeveral angles formed on the ſame arc C E D, at the ſame point E. Hence, any number of ſpherical angles, as A E C, A E D, D E B, B E C, &c. made on the ſame point E, are equal to four right angles. See Spherical *Triangle*.

Spherical *Triangle*, a triangle comprehended between three arcs of great circles of a ſphere, interſecting each other in its ſurface.

Spherical *Triangles*, *Properties of.* 1. If in two ſpherical triangles (*Plate* II. *Trigonometry*, *fig.* 3.) A B C and abc, $A = a$, $BA = ba$, and $CA = ca$; then will B, b, and the ſides including the angles, be reſpectively equal; the whole triangles are equal: that is, $BC = bc$, $B = b$, and $C = c$.

Again, if in two ſpherical triangles $A = a$, $C = c$, and $AC = ac$; then will $B = b$, $AB = ab$, and $BC = bc$.

Laſtly, if in two ſpherical triangles $AB = ab$, $AC = ac$, and $BC = bc$; then will $A = a$, $B = b$, and $C = c$: the demonſtrations of which coincide with thoſe of the like properties in plain triangles; the theorems of the congruency of rectilinear triangles extending to all other curvilinear, circular, parabolical, &c. provided their ſides be ſimilar. See Triangle.

2. In an equicrural triangle A B C (*fig.* 4.) the angles at the baſe, B and C, are equal; and if in any triangle, the angles B and C, at the baſe B C, are equal, the triangle is equicrural.

3. In every ſpherical triangle, each ſide is leſs than a ſemicircle: any two ſides taken together are greater than the third; and all the three ſides together are leſs than the periphery of a great circle; and a greater ſide is always oppoſed to a greater angle, and a leſs ſide to a leſs angle.

4. If in a ſpherical triangle B A C (*fig.* 5.) two legs, A B and B C, taken together, be equal to a ſemicircle; the baſe A C being continued to D; the external angle B C D will be equal to the internal oppoſite one B A C. If the two legs together be leſs than a ſemicircle, the external angle B C D will be greater than the internal oppoſite one A; and if the legs be greater than a ſemicircle, the external angle B C D will be leſs than the internal oppoſite one A; and the reverſe of all theſe holds, *viz.* if the angle B C D be equal to, greater, or leſs, than A, the ſides A B and B C are equal to, greater, or leſs, than a ſemicircle.

5. If in a ſpherical triangle A B C, two ſides, A B and B C, be equal to a ſemicircle, the angles at the baſe, A and C, are equal to two right ones: if the ſides be greater than a ſemicircle, the angles are greater than two right ones; and if leſs, leſs; and converſely.

6. In every ſpherical triangle, each angle is leſs than two right ones; and the three together are leſs than ſix right angles, and greater than two.

7. If in a ſpherical triangle B A C (*fig.* 5.) the ſides A B and A C be quadrants, the angles at the baſe, B and C, will be right angles. And if the intercepted angle A be a right angle, B C will be a quadrant: if A be obtuſe, B C will be greater than a quadrant; and if acute, leſs; and converſely.

8. If in a ſpherical rectangular triangle, the ſide B C (*fig.* 6.) adjacent to the right angle B, be a quadrant, the angle A will be a right angle; if B E be greater than a quadrant, the angle A will be obtuſe; and if B D be leſs than a quadrant, the angle A will be acute; and converſely.

9. If in a ſpherical rectangular triangle, each leg be either greater or leſs than a quadrant, the hypothenuſe will be leſs than a quadrant; and converſely.

10. If in a ſpherical triangle A B C (*fig.* 7.) rectangular only at B, one ſide, C B, be greater than a quadrant, and the other ſide, A B, leſs, the hypothenuſe, A C, will be greater than a quadrant; and converſely.

11. If in a ſpherical oblique-angular triangle A C B (*fig.* 8.) both angles at the baſe, A and B, be either obtuſe or acute; the perpendicular C D, let fall from the third angle C, to the oppoſite ſide A B, falls within the triangle: if one of them, A, be obtuſe, and the other, B, acute, the perpendicular falls without the triangle.

12. If in a ſpherical triangle A C, all the angles, A, B, and C, be acute, the ſides are each leſs than a quadrant. Hence, if in an oblique-angular ſpherical triangle, one ſide be greater than a quadrant, one angle is obtuſe, *viz.* that oppoſite to this ſide.

13. If in a ſpherical triangle A C B, two angles, A and B, be obtuſe, and the third, C, acute; the ſides, A C and C B, oppoſite to the obtuſe angles are greater than a quadrant; and that oppoſite to the acute angle, A B, is leſs than a qua-

a quadrant. Hence, if the two ſides be leſs than a quadrant, the two angles are acute.

14. If in a ſpherical triangle the ſeveral ſides be each greater than a quadrant; or only two of them greater, and the third be equal to a quadrant, the ſeveral angles are obtuſe.

15. If in an oblique-angular ſpherical triangle two ſides be leſs than a quadrant, and the third greater; the angle oppoſite to the greateſt will be obtuſe, and the reſt acute.

SPHERICAL *Triangles*, *Reſolution of.* See TRIANGLE.

SPHERICAL *Aſtronomy*, that part of aſtronomy which conſiders the univerſe ſuch as it appears to the eye. See ASTRONOMY.

Under ſpherical aſtronomy, then, are comprehended all the phenomena and appearances of the heavens and heavenly bodies, ſuch as we perceive them, without any enquiry into the reaſon, the theory, or the truth of them. By which it is diſtinguiſhed from *theorical* aſtronomy, which conſiders the real ſtructure of the univerſe, and the cauſes of thoſe phenomena.

In the ſpherical aſtronomy, the world is conceived to be a concave ſpherical ſurface, in whoſe centre is the earth, or rather the eye, about which the viſible frame revolves, with ſtars and planets fixed in its circumference. And on this ſuppoſition all the other phenomena are determined.

The theorical aſtronomy teaches us, from the laws of optics, &c. to correct this ſcheme, and reduce the whole to a juſter ſyſtem.

SPHERICAL *Compaſſes*. See COMPASSES.

SPHERICAL *Exceſs*, in *Trigonometry*, is the exceſs of the ſum of the three angles of any ſpherical triangle above three right angles; which exceſs in ſeconds, multiplied by the radius of the ſphere, is equal to the area of the triangle, as was firſt ſhewn by Albert Girard.

It is extremely deſirable, in geodetic operations, to be able to aſcertain the ſpherical exceſs from other principles than thoſe of the obſerved angles; theſe being very ſubject to ſmall inaccuracies, from the effect of refraction near the horizon: and nothing ſeems bettter calculated for this purpoſe, than the foregoing property of the area of the triangle; for this being, as we have ſtated above, equal to the exceſs multiplied by the radius of the ſphere, therefore, converſely, the area being known or computed on other principles, the exceſs may thence be determined, and the accuracy of the obſerved angles ſubmitted to the teſt thence obtained. Now as ſuch triangles as occur, even in the moſt extenſive ſurveys, differ but little from rectilinear ones, their areas may be computed as if they really were ſuch, with ſcarcely any perceptible error; and hence this important object is at once obtained.

The application of Albert Girard's theorem was firſt made by general Roy, or rather by Mr. Dalby, his aſſiſtant, and publiſhed in the Philoſophical Tranſactions for 1790, p. 171, where we have the following rule: "From the area of the logarithms of the triangle, computed as a plane one, in feet, ſubtract the conſtant logarithm 9.3267737, and the remainder is the logarithm of the exceſs above 180° in ſeconds nearly." This rule is very general, and, being the firſt application of this principle to geodetic computations, is highly creditable to its inventor; but it is not always the moſt conciſe; and other rules have ſince been given by different authors, which are applicable to every variety of data. We can, however, in this place only enumerate ſome of the principal ones, and muſt refer the reader for their inveſtigations to the works from which they have been ſelected.

1. The ſpherical exceſs may be found in ſeconds by the expreſſion $E = \frac{R''S}{r}$; where E is the exceſs; S is the ſurface of the triangle $= \frac{1}{2} b c \,.\, \text{ſin. } A = \frac{1}{2} a b \,.\, \text{ſin. } C = \frac{1}{2} a c \,.\, \text{ſin. } B = \frac{1}{2} a^2 \frac{\text{ſin. } B \,.\, \text{ſin. } C}{\text{ſin. } (B + C)}$; r is the radius of the earth, in the ſame meaſure as a, b, c, the ſides of the triangle; and $R'' = 206264''.8$, the ſeconds in an arc equal in length to the radius.

If this rule be applied logarithmically, then $\log. R'' = \log. \frac{1}{\text{arc } 1''} = 5.3144251$.

2. Hence is readily deduced general Roy's rule, as above given, *viz.*

$$\log. E'' = \log. (\text{area in feet}) - 9.3267737.$$

3. Since $S = \frac{1}{2} b c \,.\, \text{ſin. } A$, we ſhall manifeſtly have $E = \frac{R''}{2 r^2} b c \,.\, \text{ſin. } A$. Hence, if from the vertical angle B, of a ſpherical triangle A B C, we demit the perpendicular B D, upon the baſe A C, dividing it into two ſegments α and β, we ſhall have $b = \alpha + \beta$; and hence,

$$E = \frac{R''}{2 r^2} c \; (\alpha + \beta) \; \text{ſin. } A$$

$$= \frac{R''}{2 r^2} \alpha c \; \text{ſin. } A + \beta c \; \text{ſin. } A.$$

But the two right-angled triangles being in all practical caſes nearly rectilinear, gives $\alpha = a \; \text{coſ. } C$, and $\beta = c \; \text{coſ. } A$; whence we have

$$E = \frac{R''}{2 r^2} a c \; \text{ſin. } A \,.\, \text{coſ. } C + \frac{R''}{2 r^2} c^2 \; \text{ſin. } A \; \text{coſ. } A.$$

In like manner, the triangle A B C, which is itſelf ſo ſmall as to differ but a little from a plane triangle, gives $c \; \text{ſin. } A = a \; \text{ſin. } C$, alſo $\text{ſin. } A \,.\, \text{coſ. } A = \frac{1}{2} \text{ſin. } 2 A$, and $\text{ſin. } C \,.\, \text{coſ. } C = \frac{1}{2} \text{ſin. } 2 C$; therefore, finally,

$$E = \frac{R''}{4 r^2} a^2 \,.\, \text{ſin. } 2 C + \frac{R''}{4 r^2} c^2 \; \text{ſin. } 2 A.$$

From which theorem a table may be formed, whence the ſpherical exceſs may be found; entering the table with each of the ſides above the baſe and its adjacent angle as arguments.

4. If the baſe b, and height h, of the triangle be given, then we have evidently $E = \frac{1}{2} b h \frac{R''}{r^2}$. Hence reſults the following ſimple logarithmic rule: Add the logarithm of the baſe of the triangle, taken in feet, to the logarithm of the perpendicular, taken in the ſame meaſure, and deduct from the ſum the conſtant log. 9.6278037; and the remainder will be the common logarithm of the ſpherical exceſs in ſeconds and decimals.

5. Again, when the three ſides of the triangle are given, then

$$\log. E = \tfrac{1}{2} \left(\log. s + \log. (s - a) + \log. (s - b) + \log. (s - c) \right) - 9.3267737;$$

where $s = \frac{1}{2}$ ſum of the ſides, or $s = (a + b + c) \div 2$.

The two latter formulæ are in fact only particular caſes of Roy's general theorem.

6. When any two ſides, a, b, and their contained angle C, are given, then we have

$$\text{cot.}\ \tfrac{1}{2}\,\text{E} = \frac{\text{cot.}\ \frac{1}{2}a\ .\ \text{cot.}\ \frac{1}{2}b + \text{coſ. C}}{\text{ſin. C}}.$$

7. When the three ſides are given, we may alſo, inſtead of the formula in art. 5, make uſe of the following elegant theorem, diſcovered by Simon L'Hullier, *viz.*

$$\text{tan.}\ \tfrac{1}{4}\,\text{E} = \surd\left(\text{tan.}\ \frac{a+b+c}{4}\ .\ \text{tan.}\ \frac{a+b-c}{4}\ .\ \text{tan.}\ \frac{a-b+c}{4}\ .\ \text{tan.}\ \frac{-a+b+c}{4}\right).$$

One or other of theſe rules will apply to all caſes in which the ſpherical exceſs will be required.

We ſhall conclude this ſhort article with one or two examples of its application, as given by general Roy, Phil. Tranſ. 1790, p. 172.

Names of Stations.		*Obſerved Angles.*
Hanger-hill Tower	(a)	42° 2′ 32″
Hampton Poor-houſe	(b)	67 55 39
King's Arbour	(c)	70 1 48
		179 59 59

Diſtance in Feet.

(a) from (b) = 38461.12
(a) from (c) = 27404.7

Hence, making the diſtance from (a) to (c) the baſe of the triangle, the perpendicular on that baſe will be equal to 38461.12 × ſin. 42° 2′ 32″; and, therefore, the area of the triangle =

$$\frac{\text{baſe} \times \text{perp.}}{2} = 24704.7 \times 19230.56 \times \text{ſin.}\ 42^\circ\ 2'\ 32''.$$

Computation.

Log. ſin. 42° 2′ 32″ = 9.8258661
Log. 24704.7 = 4.3927761
Log. 19230.56 = 4.2839906
18.5026328

Taking away 10 for radius, we have 8.5026328 for the log. of the area in feet.

Whence from - - 8.5026328
Take conſt. log. - - 9.3267737
Correſp. numb. .14992 = 1.7158591

Whence the ſpherical exceſs in ſeconds is .14992″, or 0″.15 *nearly.*

Again, as a ſecond example.

Names of Stations.		*Obſerved Angles.*
Hundred Acres	(d)	53° 58′ 35″.75
Hanger-hill Tower	(e)	68 24 44
St. Anne's Hill	(f)	57 36 39.5
		179 59 59.25

Diſtance in Feet.

(d) from (e) = 71934.2
(d) from (f) = 79211.22

Log. ſin. 53° 58′ 35″.75 = 9.9078237
Log. 35967.1 = 4.5559054
Log. 79211.22 = 4.8987866
Sum minus radius = 9.3625207
Subtract conſt. log. = 9.3267737
Correſp. numb. 1.0858 = 0.0357470

Whence the ſpherical exceſs is 1″.0858.

In this manner the computed ſpherical exceſs will enable the obſerver to examine the accuracy of his obſervations, and in ſome degree to correct them; after which he may proceed to calculate the ſides of the triangles by the rules of ſpherical trigonometry, or by Legendre's theorem, *viz.* "a ſpherical triangle being propoſed, of which the ſides are very ſmall, relatively to the radius of the ſphere; if, from each of the angles, one-third of the exceſs of the ſum above two right angles be ſubtracted, the angles ſo diminiſhed may be taken for the angles of a rectilinear triangle, the ſides of which are equal in length to thoſe of the propoſed ſpherical triangle."

SPHERICAL *Geometry*, the doctrine of the ſphere; particularly of the circles deſcribed on the ſurface thereof, with the method of projecting the ſame on a plane; and meaſuring their arcs and angles when projected.

SPHERICAL *Numbers.* See CIRCULAR *Numbers.*

SPHERICAL *Trigonometry.* See *Spherical* TRIGONOMETRY.

SPHERICITY, the quality of a ſphere; or that by which a thing becomes ſpherical or round.

The ſphericity of pebbles, fruits, berries, &c. as alſo of drops of water, quickſilver, &c. and of bubbles of air under water, &c. Dr. Hook takes to ariſe from the incongruity of their particles with thoſe of the ambient fluid, which prevents their coaleſcing; and by preſſing on them, and encompaſſing them all round equally, turns them into a round form.

This, he thinks, appears evidently from the manner of making ſmall round ſhot of ſeveral ſizes, without caſting the lead into any moulds; from drops of rain being formed, in their fall, into round hail-ſtones; and from drops of water falling on ſmall duſt, ſand, &c. which ſoon produce an artificial round maſs; and from the ſmall, round, red-hot balls, formed by the colliſion or fuſion of flint and ſteel, in ſtriking fire.

But all theſe caſes of ſphericity ſeem better accounted for from the great principle of attraction; by which the parts of the ſame fluid drop, &c. are all naturally ranged as near the centre as poſſible, which neceſſarily induces a ſpherical figure; and, perhaps, a repelling force between the particles of the drop, and of the medium, contributes alſo not a little thereto. See ATTRACTION and COHESION.

SPHERICS, the *doctrine of the ſphere*, particularly of the ſeveral circles deſcribed on its ſurface; with the method of projecting the ſame in plano.

The principal matters ſhewn here are as follow:

1. If a ſphere be cut in any manner, the plane of the ſection will be a circle, whoſe centre is in the diameter of the ſphere.

Hence, 1. The diameter H I (*Plate* II. *Trigonometry*, *fig.* 9.) of a circle, paſſing through the centre C, is equal to the diameter A B of the generating circle; and the diameter of a circle, as F E, that does not paſs through the centre, is equal to ſome chord of the generating circle.

Hence, 2. As the diameter is the greateſt of all chords, a circle paſſing through the centre is the greateſt circle of the ſphere; and all the reſt are leſs than the ſame.

Hence alſo, 3. All great circles of the ſphere are equal to one another.

Hence alſo, 4. If a great circle of the ſphere paſs through any given point of the ſphere, as A, it muſt alſo paſs through the point diametrically oppoſite to it, as B.

Hence alſo, 5. If two great circles mutually interſect each other, the line of ſection is the diameter of the ſphere; and therefore two great circles interſect each other in points diametrically oppoſite.

Hence alſo, 6. A great circle of the ſphere divides it into two equal parts or hemiſpheres.

2. All great circles of the ſphere cut each other into two equal parts; and, converſely, all circles that thus cut each other are great circles of the ſphere.

3. An arc of a great circle of the ſphere, intercepted between another arc H I L (*fig.* 10.), and its poles A and B, is a quadrant. That intercepted between a leſs circle D E F, and one of its poles A, is greater than a quadrant; and that between the ſame, and the other pole B, leſs than a quadrant; and converſely.

4. If a great circle of the ſphere paſs through the poles of another, that other paſſes through the poles of this. And if a great circle paſs through the poles of another, the two cut each other at right angles; and converſely.

5. If a great circle, as A F B D, paſs through the poles A and B of a leſſer circle D E F, it cuts it into equal parts, and at right angles.

6. If two great circles, A E B F and C E D F, (*fig.* 11.) interſect each other in the poles E and F of another great circle A C B D; that other will paſs through the poles I and *i*, H and *h*, of the circles A E B F and C E D F.

7. If two great circles, A E B F and C E D F, cut each other mutually; the angle of obliquity, A E C, will be equal to the diſtance of the poles H, I.

8. All circles of the ſphere, as G F and L K (*fig.* 12.) equally diſtant from its centre C, are equal; and the farther they are removed from the centre, the leſs they are. Hence, ſince of all parallel chords, only two, G F and L K, are equally diſtant from the centre; of all the circles parallel to the ſame great circle, only two are equal.

9. If the arcs F H and K H, and G I and I L, intercepted between a great circle I M H, and the leſſer circles G N F and L O K, be equal, the circles are equal.

10. If the arcs F H and G I, of the ſame great circle A I B H, intercepted between two circles G N F and I M H, be equal, the circles are parallel.

11. An arc of a parallel circle, I G, (*fig.* 1.) is ſimilar to an arc of a great circle, A E; if each be intercepted between the ſame great circles C A F and C E F.

Hence, the arcs A E and I G have the ſame ratio to their peripheries; and, conſequently, contain the ſame number of degrees. And hence the arc I G is leſs than the arc A E.

12. The arc of a great circle is the ſhorteſt line which can be drawn from one point of the ſurface of the ſphere to another; and the lines between any two points on the ſame ſurface are the greater, as the circles of which they are arcs are the leſs.

Hence, the proper meaſure, or diſtance, of two places on the ſurface of the ſphere, is an arc of a great circle intercepted between the ſame. See more on this ſubject in Theodoſii Elem. Sphær. apud Dechales Curſus Mathematicus, tom. i. p. 145, &c.

SPHEROID, Sphæroides, Σφαιροειδης, formed from σφαιρα, *ſphæra*, and ειδος, *ſhape*, in *Geometry*, a ſolid approaching to the figure of a ſphere, though not exactly round, but oblong; as having one of its diameters bigger than the other; and generated by the revolution of a ſemi-ellipſis about its axis.

When it is generated by the revolution of the ſemi-ellipſis about its greater or tranſverſe axis, it is called an *oblong* or *prolate* ſpheroid: and when generated by the revolution of an ellipſis about its leſs or conjugate axis, an *oblate* ſpheroid.

The contour of a dome, Daviler obſerves, ſhould be half a ſpheroid. Half a ſphere, he ſays, is too low to have a good effect below.

For the ſolid dimenſion of a ſpheroid, multiply continually together the fixed axis, the ſquare of the revolving axis, and the number .52359877, or $\frac{1}{6}$ of 3.14159, and the laſt product will be the ſolidity: *i. e.* $\frac{1}{6}pttc =$ the oblate, and $\frac{1}{6}ptcc =$ the oblong ſpheroid, where $p = 3.14159$, $t =$ the tranſverſe, and $c =$ the conjugate axis of the generating ellipſis. Or, multiply the area of the generating ellipſe by $\frac{2}{3}$ of the revolving axis, and the product will be the content of the ſpheroid: *i. e.* $\frac{2}{3}t\text{A} =$ the oblate, and $\frac{2}{3}c\text{A} =$ the oblong ſpheroid; where A is the area of the ellipſe. *E. g.* Required the content of an oblate, and of an oblong ſpheroid, the axes being 50 and 30. Thus, $50 \times 30 \times .78539816 = 1178.09724 =$ the area of the ellipſe. And $1178.09724 \times \frac{2}{3} \times 30 = 23561.9448 =$ the oblong ſpheroid: and $1178.09724 \times \frac{2}{3} \times 50 = 39269.908 =$ the oblate one.

Dr. Hutton has demonſtrated the rule above given in the following manner. Put $f = \text{BI}$ the fixed ſemi-axis, (*Plate* XIV. *Geometry*, *fig.* 3.) $r = \text{IM}$ the revolving ſemi-axis of the ſpheroid, $a = \text{SI}$ any ſemi-diameter of the ſection N B M, $b = \text{IK}$ its ſemi-conjugate, $y = \text{AE}$ an ordinate to the diameter S I, or a ſemi-axis of the elliptic ſection A F C parallel to K L, and $z = \text{EF}$ its other ſemi-axis, alſo $x = \text{EI}$, $s =$ the ſine of the angle A E S, or of the angle K I S, to the radius 1, and $p = 3.14159$.

Then, by the property of the ellipſe K S L, $aa : bb :: aa - xx : bb \times \frac{aa - xx}{aa} = yy$; and $b : r :: y : \frac{ry}{b} = z$. But the fluxion of the ſolid K A C L is $psyz\dot{x} = \frac{psryy\dot{x}}{b}$, by writing for z its value $\frac{ry}{b}$, $= pbsr\dot{x} \times \frac{aa - xx}{aa}$, by ſubſtituting for yy its value $bb \times \frac{aa - xx}{aa}$, $= pfrr\dot{x} \times \frac{aa - xx}{aaa}$, by putting for abs its value rf; and hence the fluent $pfrrx \times \frac{aa - \frac{1}{3}xx}{aaa}$, or $\frac{1}{3}pfrr \times \frac{3aa - xx}{aaa}$, will be the value of the fruſtum K A C L; which, when E I or x becomes S I or a, gives $\frac{2}{3}pfrr$ for the value of the ſemi-ſpheroid K S L; or the whole ſpheroid $= \frac{1}{6}p\,\text{FRR}$, putting F and R for the whole fixed and revolving axes. Q.E.D.

Corol. 1.—From the foregoing demonſtration it appears that the value of the general fruſtum KAECL is expreſſed by $\frac{1}{3}pfrrx \times \frac{3aa - xx}{aaa}$.

And if for fr be ſubſtituted its value abs, the ſame fruſtum will alſo be expreſſed by $\frac{1}{3}pbrsx \times \frac{3aa - xx}{aa}$.

Alſo, if for aa be put its value $\frac{bbxx}{bb - yy}$, the laſt expreſſion will become $\frac{1}{3}prsx \times \frac{2bb + yy}{b}$, or $\frac{1}{3}psx \times \left(2br + \frac{ryy}{b}\right)$; which, by writing z inſtead of its value $\frac{ry}{b}$, gives $\frac{1}{3}psx \times (2br + yz)$ for the value of the fruſtum, *viz.* the ſum of the area of the leſs end, and twice that of the greater, drawn into one-third of the altitude or diſtance of the ends.

And out of this laſt expreſſion may be expunged any one of the four quantities b, r, y, z, by means of the proportion $b : r :: y : z$.

When the ends of the fruſtum are perpendicular to the fixed axis, then a is $= f$, and the value of the fruſtum becomes $\frac{1}{3}prrx \times \frac{3ff - xx}{ff}$ for the value of the fruſtum whoſe ends are perpendicular to the fixed axis, its altitude being x.

And when the ends of the fruſtum are parallel to the fixed axis, a is $= r$, and the expreſſion for ſuch a fruſtum becomes $\frac{1}{3}pfx \times \frac{3rr - xx}{r}$.

Corol. 2.—If to or from $\frac{2}{3}pfrr$, the value of the ſemi-ſpheroid, be added or ſubtracted $\frac{1}{3}pfrrx \times \frac{3aa - xx}{aaa}$, the value of the general fruſtum KACL, there will reſult $\frac{1}{3}pfrrhh \times \frac{3a - h}{aaa}$ for the value of a general ſegment, either greater or leſs than the ſemi-ſpheroid, whoſe height, taken upon the diameter paſſing through its vertex and centre of its baſe, is $h = a \pm x$.

When a coincides with f, the above expreſſion becomes $\frac{1}{3}prrhh \times \frac{3f - h}{ff}$ for the value of a ſegment whoſe baſe is perpendicular to the fixed axis.—And here, if we put R for the radius of the ſegment's baſe, and for rr its value $\frac{RRff}{2fh - hh}$, the ſaid ſegment will become $\frac{1}{3}pRRh \times \frac{3f - h}{2f - h}$.

And when a coincides with r, the general expreſſion will become $\frac{1}{3}pfhh \times \frac{3r - h}{r}$ for the value of the ſegment whoſe baſe is parallel to the fixed axis. And if we put F, R, for the two ſemi-axes of the elliptic baſe of this ſegment, reſpectively correſponding or parallel to f, r, the ſemi-axes of the generating ellipſe, when parallel to the baſe of the ſegment, and for $\frac{f}{r}$ and r ſubſtitute their values $\frac{F}{R}$ and $\frac{RR + hh}{2h}$, the ſaid fruſtum will be expreſſed by $\frac{1}{3}pFh \times \frac{3RR + hh}{2R}$, in which the dimenſions of itſelf only are concerned.

Corol. 3.—A ſemi-ſpheroid is equal to $\frac{2}{3}$ds of a cylinder, or to double a cone of the ſame baſe and height; or they are in proportion as the numbers 3, 2, 1. For the cylinder is $= 4nfrr = \frac{12}{3}nfrr$, the ſemi-ſpheroid $= \frac{8}{3}nfrr$, and the cone $= \frac{4}{3}nfrr$.

Corol. 4.—When $f = r$, the ſpheroid becomes a ſphere, and the expreſſion $\frac{8}{3}fnrr$ for the ſemi-ſpheroid becomes $\frac{8}{3}nr^3$ for the ſemi-ſphere. And in like manner, f and r being ſuppoſed equal to each other in the values of the fruſtums and ſegments of a ſpheroid, in the preceding corollaries, will give the values of the like parts of a ſphere.

Corol. 5.—All ſpheres and ſpheroids are to each other as the fixed axes drawn into the ſquares of the revolving axes.

Corol. 6.—Any ſpheroids and ſpheres, of the ſame revolving axis, as alſo their like or correſponding parts cut off by planes perpendicular to the ſaid common axis, are to one another as their other or fixed axes. This follows from the foregoing corollaries.

Corol. 7.—But if their fixed axes be equal, and their revolving axes unequal, the ſpheroids and ſpheres, with their like parts terminated by planes perpendicular to the common fixed axis, will be to each other as the ſquares of their revolving axes.

Corol. 8.—An oblate ſpheroid is to an oblong ſpheroid, generated from the ſame ellipſe, as the longer axis of the ellipſe is to the ſhorter. For, if T be the tranſverſe axis, and C the conjugate; the oblate ſpheroid will be $= \frac{2}{3}nT^2C$, and the oblong $= \frac{2}{3}nC^2T$; and theſe quantities are in the ratio of T to C.

Corol. 9.—And if about the two axes of an ellipſe, be generated two ſpheres and two ſpheroids, the four ſolids will be continual proportionals, and the common ratio will be that of the two axes of the ellipſe; that is, as the greater ſphere, or the ſphere upon the greater axis, is to the oblate ſpheroid, ſo is the oblate ſpheroid to the oblong ſpheroid, ſo is the oblong ſpheroid to the leſs ſphere, and ſo is the tranſverſe axis to the conjugate. For theſe four bodies will be as T^3, T^2C, TC^2, C^3, where each term is to the conſequent one as T to C.

To find the content of an univerſal ſpheroid, or a ſolid conceived to be generated by the revolution of a ſemi-ellipſe about its diameter, whether that diameter be one of the axes of the ellipſe or not. 1. Divide the ſquare of the product of the axes of the ellipſe by the axis of the ſolid, or the diameter about which the ſemi-ellipſe is conceived to revolve: multiply the quotient by .5236, and the product will be the content required. That is, $\frac{T^2C^2}{d} \times .5236 =$ the content; T and C being the tranſverſe and conjugate axes of the ellipſe, and d the axis of the ſolid.

Or, 2. The continual product of .5236, the diameter about which the revolution is made, the ſquare of its conjugate diameter, and the ſquare of the ſine of the angle made by thoſe diameters, the radius being 1, will be the content. That is, $dccss \times .5236 =$ the content; c being the conjugate diameter to d, and s the ſine of the angle made by the diameters. For the demonſtration of this rule, ſee Hutton, ubi infra.

Hence, if $d = T$, the rule becomes $\frac{1}{6}pTC^2$ for the oblong ſpheroid: and if $d = C$, it will be $\frac{1}{6}pCT^2$ for the oblate ſpheroid: and if T, C, and d, be all equal, the rule will be $\frac{1}{6}pd^3$ for the ſphere. See MENSURATION. Hutton's Menſuration.

For the method of finding the ſuperficies of a ſpheroid, ſee SUPERFICIES; and for the ſolidity, ſee SOLIDITY, and the preceding article.

Dr. Halley has demonſtrated, that in a ſphere, Mercator's nautical meridian line is a ſcale of logarithmic tangents of the half complements of the latitudes. But as the earth has been found to be a ſpheroid, this figure will make ſome alteration in the numbers reſulting from Dr. Halley's theorem. Mr. Maclaurin has therefore given us a rule, by which the meridional parts to any ſpheroid may be found with the ſame exactneſs as in a ſphere. We have alſo an ingenious treatiſe of Mr. Murdoch's on the ſame ſubject. See Phil. Tranſ. N° 219.

Mr. Cotes has alſo demonſtrated the ſame propoſition, Harm. Menſ. p. 20, 21. See MERIDIONAL *Parts*.

SPHEX, in *Entomology*, a genus of inſects of the order Hymenoptera, of which the generic character is as follows. The mouth is formed with an entire jaw; the mandibles are horny, incurved, and toothed; the lip is horny and membranaceous at the tip; it has four feelers; the antennæ have about ten articulations; the wings in each ſex are plane, incumbent, and not folded; the ſting is pungent, and concealed within the abdomen. The inſects of this genus are ſaid to be the moſt ſavage and rapacious of this claſs of beings: they attack whatever comes in their way, and by means of a poiſonous ſting, overcome and devour others far beyond their own ſize. Thoſe of diviſion B, hereafter to be deſcribed, are found chiefly on umbellate plants; the larvæ are without feet, ſoft, and inhabit the body of ſome inſect, on whoſe juices they exiſt; the pupa has rudiments of wings.

"As the inſects," ſays Dr. Shaw, "of the genus Ichneumon depoſit their eggs in the bodies of other *living* inſects, ſo thoſe of the genus Sphex depoſit their's in *dead* ones, in order that the young larvæ, when hatched, may find their proper food." There are more than a hundred ſpecies of the genus Sphex, which are ſeparated into diviſions.

Species.

A. *Antennæ ſetaceous; Lip entire; and no Tongue.*

APPENDIGASTER. This ſpecies is black; the abdomen is petiole, very ſhort, and placed on the back of the thorax; the hind-legs are very long. This is found in divers parts of Europe, Africa, and New Holland.

* MACULATA. Thorax ſpotted; firſt ſegment of the abdomen with a white dot on each ſide; the ſecond is edged with white. It is, as the aſteriſk denotes, an Engliſh inſect. There is a ſpecimen of it in ſir Joſeph Banks's muſeum.

FASCIATA. Black; abdomen with two white bands, the firſt interrupted; and the tail is white. It is found in different parts of Italy. The thorax is black, covered with ſilvery down on the fore-part; the fore-margin is marked with a white line; the wings are white, but tipped with brown.

SESSILIS, ſo named on account of its ſhort, cylindrical, ſeſſile abdomen. The inſect is black. It inhabits France; is very like the S. appendigaſter.

PUNCTUM. This is black; but the tail is marked with a white dot. It is an Italian inſect.

NIGRITIA. This alſo is black; the upper wings are marked with a brown band.

B. *Antennæ filiform; Lip emarginate; with a Briſtle on each ſide; the Tongue is inflected and trifid.*

Of this ſection there are two ſubdiviſions; the one has a petiolate abdomen, that of the other is ſeſſile.

a. *Abdomen petiolate.*

LUTARIA. Black; ſecond and third ſegments of the abdomen rufous; the lip is ſilvery. It inhabits Kiel.

THOMÆ. Black; abdomen rufous; the petiole, and ſpot on the back, black. It inhabits St. Thomas's iſland.

FERVENS. This is likewiſe black; the abdomen is ferruginous; the wings are brown. It inhabits India.

CYANIPENNIS. Villous, blue; fore-part of the thorax and abdomen grey; the wings are blue. It inhabits Cayenne, and is large. This is a very beautiful inſect; the head is blue; the mandibles and antennæ are black; the abdomen blueiſh-grey; the petiole black; legs black; the joints yellowiſh.

HÆMORRHOIDALIS. Black; lip, tail, and legs, ferruginous. Inhabits Africa. A ſpecimen is preſerved in the muſeum of ſir Joſeph Banks.

ARGENTEA. Gloſſy-black; front villous, ſilvery; the wings are white, but tipt with brown. It inhabits Coromandel, and is a large inſect.

RUFIPENNIS. Black; wings ferruginous, tipt with brown. It inhabits Tranquebar, and is large.

FLAVIPENNIS. Black; front golden; abdomen rufous; the petiole and tips are black. It inhabits Italy.

PENNSYLVANICA. This is of a blackiſh hue; the abdomen is of a full black; but the wings are inclining to a violet. It inhabits America and New Holland.

VIOLACEA. Blue; wings white, tipt with brown; the antennæ are black. It is found at the Cape of Good Hope.

CYANEA. Blue; wings azure, tipt with brown; the antennæ are black. It inhabits North America.

AURULEATA. Head and thorax covered with gold down; the abdomen is black; the baſe and legs rufous. It is an inhabitant of Tranquebar.

TOMENTOSA. The head and thorax of the inſects of this ſpecies are covered with a gold down; the abdomen is black; the baſe and legs are rufous. It inhabits Sierra Leone.

FEMORATA. This is blue; the abdomen is black; the hind-thighs are rufous. It inhabits Italy.

TIBIALIS. Hairy, black-blue; hind-ſhanks ferruginous; wings black. It inhabits the Cape of Good Hope. A ſpecimen is preſerved in the muſeum of ſir Joſeph Banks.

FLAVIPES. Villous, black, with a yellow dot before the wings; the legs are yellow; the thighs black. It inhabits America.

ATRA. This is quite black, excepting the lip, which is ſilvery villous; wings as long as the abdomen. It inhabits Italy.

FIGULUS. Smooth, black; ſegments of the abdomen at the edges and lip lucid. It inhabits Upſal, in the holes and crevices of wooden partitions, abandoned by all other inſects. According to Dr. Shaw, this inſect, when it has found a convenient cavity for the purpoſe, ſeizes on a ſpider, which it kills, and depoſits it at the bottom; then laying her egg in it, ſhe cloſes up the orifice of the cavity with clay; the larva, which reſembles the maggot of a bee, having devoured the ſpider, ſpins itſelf up a duſky ſilken web, and changes into a chryſalis, out of which, within a certain number of days, proceeds a complete inſect, which is black, with a ſlightly foot-ſtalked abdomen, the edges of the ſeveral ſegments being of a brighter appearance than the reſt of the body. The female of this ſpecies prepares ſeveral ſeparate holes, or nets, in each of which ſhe places a dead inſect and an egg; each cell coſting her the labour of about two days.

Lunata. The abdomen of this inſect is black; the firſt ſegment is marked with a yellow lunule. It inhabits America, as does the next.

Affinis. Villous, black; the firſt joint of the antennæ, ſcutel, and ſhanks, are yellow.

Jamaicensis. This, as its name implies, is found in Jamaica. The abdomen is black; the firſt ſegment, and edge of the others, are yellow.

Erythrocephala. Black; head, baſe of the petiole, and legs, ferruginous. It inhabits Malabar. A ſpecimen is kept in the muſeum of ſir Joſeph Banks.

* Spirifex. Black; thorax hairy, and immaculate; petiole of one joint, yellow; as long as the abdomen. There is a variety, of which the petiole and joints of the legs are half yellow. It is found in this country, in divers parts of Europe, and alſo in Africa, particularly in Egypt, in cylindrical cavities wrought within like a honeycomb, on the ſides of cliffs, and in the mud walls of cottages.

Madraspatana. Black; thorax hairy, and ſpotted with yellow; the petiole is yellow, and as long as the abdomen. It inhabits Malabar.

Clavus. Black; thorax ſpotted; abdomen blueiſh; the petiole long, rufous, with a black band. This is an inhabitant of New Holland.

Holosericea. Black, with a ſilvery down; abdomen ferruginous; the petiole is black, and the tail blue. It is found in Barbary.

Pubescens. Black, with ſilvery down; the abdomen is ferruginous, with a black petiole. It inhabits Guinea, and is found among the graſs.

Cincta. Black, with ſilvery down; the ſegments of the abdomen are edged with white. This, like the laſt, is found in Guinea.

Lobata. Green-blue; thorax with a diſtinct fore-lobe; the wings are ſub-ferruginous. It is an inhabitant of Africa.

Ciliata. Teſtaceous; abdomen blue; mandibles elongated and ciliate. This is an Indian inſect.

Compressa. Shining green; the hind-thighs are compreſſed, ferruginous. It inhabits Malabar.

Sibirica. Poliſhed braſſy-green; the abdomen is blue, An inhabitant of Siberia.

Ichneumonea. Fulvous; abdomen black, with a ferruginous baſe. It is found in divers parts of America.

Hirtipes. Hairy, duſky; abdomen ſhining black; wings teſtaceous. It inhabits Guinea.

Albifrons. Glabrous, black; front covered with a ſilvery brown; wings white, with a black baſe. This alſo is found in Guinea.

Maxillosa. Black, with ſilvery down; abdomen ferruginous at the baſe; the mandibles are projected, curved, and toothed. It is a large inſect, and is found in Barbary.

Unicolor. Duſky-brown, with cinereous down. It is found in Spain, on umbellate flowers,

Indostanee. Black; wings blueiſh-black, with a hyaline thinner margin. Found in Europe and India.

Clavipes. Black; petiole ferruginous, clavate, of one joint; legs clavate. This is a ſmall inſect, and is found in ſeveral parts of Europe.

Austriaca. Black; baſe of the abdomen with a ſulphur-coloured band and two dots; the legs are varied with ſulphur; the hind-thighs are thickened. It inhabits, as its name denotes, Auſtria.

Bidens. Black; head and antennæ ferruginous; the abdomen is marked with four yellow ſpots; the thorax is two-ſpined. It inhabits Mauritania, and is a large inſect.

Insubrica. Black; front, mouth, ſcutel, and two bands on the abdomen, of a pale yellow. It inhabits Padua; breeds in chimneys and windows, in the ſame neſt with the Ichneumon ſeductor.

b. *Abdomen ſeſſile.*

Morio. Black, immaculate; wings dark brown. It inhabits New Holland.

Collaris. Black-blue; fore-lobe of the thorax fulvous. It inhabits New Holland.

Frontalis. Black; front and fore-lobe of the thorax yellow. It inhabits New Holland.

Analis. Glabrous, black; abdomen ferruginous at the tip; wings white. It inhabits India.

Similis. This inſect is glabrous, black, abdomen ferruginous at the tip; the wings are white.

Assimilis. Black; antennæ, tail, and legs, rufous; wings blue; the baſe and tip white. This is found at Tranquebar.

Dimidiata. Black; the head and fore-part of the thorax dull ferruginous; the wings are black. This is an inhabitant of Barbary.

* Fusca. Black, glabrous; baſe of the abdomen ferruginous. This inhabits gravelly places in Europe: after having deſtroyed the larva of a moth, it depoſits its eggs in its carcaſe, and then digs a hole and buries it.

Viatica. Black, downy; fore-part of the abdomen ferruginous, with black belts; wings brown.

Ursus. Black, hairy; ſecond ſegment of the abdomen ferruginous; wings black.

Amethystina. Blue; antennæ and legs black. It inhabits Santa Cruz.

Cingulata. Black; front ſtreak on the fore-part of the thorax, and edges of the abdominal ſegments, cinereous. It inhabits New Holland.

Nigra. Black; ſegments of the abdomen with lucid margins.

Labiata. Black; ſegments of the abdomen edged with cinereous; the wings are teſtaceous, tipt with brown. It inhabits the South American iſlands.

Variegata. Black, ſpotted with white; thorax rufous under the ſcutel; the wings are tipt with brown. This is found in Saxony.

Sanguinolenta. Black; thorax rufous before and behind; ſegments of the abdomen lucid at the margin. This is a very ſmall inſect, and is found in ſeveral parts of Germany.

Mixta. Black, varied with yellow; abdomen yellow, with three black bands. This is an American inſect.

Maura. Black; hind-thighs rufous; inhabits Tranquebar.

Hyalinata. Black; four hind-thighs rufous; wings hyaline. Found in Saxony.

Fuscata. Black; abdomen with a white tranſverſe dot on each ſide; hind-thighs rufous; wings tipt with brown. It inhabits Saxony.

Sex-punctata. Black, with two white dots under the ſcutel, and four on the abdomen; wings tipt with brown.

Bi-fasciata. Black, immaculate; wings with two black bands. This is an inhabitant of Paris.

Gibba. Black; abdomen ferruginous, tipt with brown; upper wings brown at the tip. This is found in divers parts of Europe.

Fasciata. Black; antennæ rufous; wings white, with two brown bands. This is found in New Holland, as is the next.

Cinerea. Cinereous; ſegments of the abdomen black at the baſe, and brown at the tip.

Tropica. Black; ſecond ſegment of the abdomen ferruginous. This is found in different parts of America.

Fugax. Thorax covered with gold down; abdomen ferruginous; wings yellowiſh, with a brown band.

Aurata. Head and thorax with gold down; abdomen black, the edges of the ſegments cinereous. This is found in the Eaſt Indies.

Nitida. Ferruginous; thorax golden behind; wings yellowiſh. It inhabits New Holland.

* **Rufipes.** Black; the ſegments of the abdomen are marked with a white dot on each ſide; the wings are tipt with brown. Found in England, and on divers parts of the European continent.

Bi-punctata. Black, glabrous; abdomen marked with two white dots and a band behind; the wings are tipt with brown. This is an European inſect.

Nigricornis. Black; head and thorax rufous. It is found in New Holland.

Exaltata. Black; abdomen rufous, tipt with black; wings brown at the tip, with a white dot.

Maculata. Black; thorax ſpotted with white; firſt ſegment of the abdomen rufous, the reſt with a tranſverſe white line on each ſide. It inhabits Kiel.

Tricolorata. Black; abdomen with ſilver lunules on each ſide, the baſe is rufous, the tip black. This is a Barbary inſect.

Guttata. Black, glabrous; thorax ſpotted with white; abdomen rufous, with tranſverſe dots, and black before the tip. This is very like the S. maculata, and is found in Italy.

Abdominalis. Black; thorax with a cinereous band before; abdomen rufous; wings tipt with brown. It inhabits Braſil.

Capensis. Black; antennæ, ſhanks, and wings teſtaceous, the latter tipt with brown. It inhabits the Cape of Good Hope.

Nigrita. Black; wings blue. Inhabits Malabar.

Turcica. Black; thorax with a cinereous band before; abdomen rufous; wings black. It is an inhabitant of Braſil.

Nigripes. Black; abdomen ferruginous; wings duſky; legs black. It inhabits Africa.

Villosa. Black; abdomen villous, teſtaceous; wings deep black; legs rufous. It is found at Malabar, and is very ſmall.

Discolor. Black, glabrous; wings yellow, tipt with black. It is found in Barbary.

Flava. Black; head, thorax, and tail, ferruginous; wings yellow, tipt with brown. It is found in the Eaſt Indies.

Bicolorata. Black; head, tip of the abdomen, and wings, yellow, the latter tipt with brown. This is a New Holland inſect.

Speciosa. Deep black; wings rufous, tipt with white.

Fulvipennis. Black; head, fore-part of the thorax, tail and legs, rufous; wings fulvous, tipt with blue. This is an inhabitant of India.

Nobilis. This ſpecies is varied with ſilver and black; wings white, with two black bands. It inhabits Cayenne.

Brevicornis. Black; thorax ferruginous; abdomen with ſix white ſpots. It is found in Barbary: in a variety the abdomen is immaculate.

Ocellata. Black; legs teſtaceous; wings black, with an ocellar ferruginous ſpot on the upper pair. Found in Africa.

Ruficornis. Blue; antennæ rufous; legs black.

Quadri-punctata. Black; antennæ, ſtreaks on the fore-part of the thorax and ſcutel; there are four dots on the abdomen, and the wings are ferruginous. It is found in Spain.

Cærulea. Blue; wings ferruginous, upper pair whitiſh at the tip. It inhabits South America, as does the next.

Stellata. Blue; wings black, upper pair with a rufous ſpot in the middle, and whitiſh at the tip.

Plumbea. Lead-colour; antennæ black; upper wings tipt with brown. It is found in Spain, and is very ſmall.

Pectinipes. Black, glabrous; fore-part of the abdomen ferruginous; fore-legs ciliate.

Variegata. Entirely black; wings ſpotted with white. Seen in divers parts of Europe.

Antarctica. Black; antennæ and legs ferruginous; is about the ſize of a waſp, and is found at the Cape of Good Hope.

Palmipes. Black; thorax with two yellow dots at the tip, and one at the baſe; the fore-legs are palmate. It inhabits Sweden.

Ephippica. Black; front blueiſh; abdomen with a double ferruginous band. It is the ſize of a gnat, and inhabits Sweden.

Stigma. Wings angular, grey-brown and reddiſh beneath, with white ſpots. It is an inhabitant of the Cape.

Indica. Black; antennæ and legs ferruginous; wings blueiſh-black. It is found in South America.

Colon. Black; antennæ and legs rufous; thorax green; wings with two black ſpots. It inhabits Sweden.

Mauritanica. Black; head, antennæ, and legs, ferruginous, with a black border. It inhabits Mauritania, and is reckoned among the large inſects of this genus.

Collaris. Black; wings brown, with a white band in the middle and at the end; antennæ and legs teſtaceous. Inhabits Spain, and is the ſize of a common ant. Its neck is yellow.

Coronata. Abdomen black, with two yellow belts and dots; head and thorax ſpotted with yellow. It inhabits Switzerland.

* **Xanthocephalus.** Black; front yellow; abdomen and legs ſpotted with yellow. It inhabits England.

* **Spinosa.** Black; thorax with a ſpine on each ſide behind; the lip and breaſt are ſilvery. It inhabits England.

Albomaculata. Black; abdomen ferruginous at the baſe; wings brown, with a white ſpot at the tip.

Tricolor. Black; ſegments of the abdomen very varied in number, ſome of them are teſtaceous, and others dotted with white.

Boops. Black; three ſegments of the abdomen and tarſi teſtaceous. It is an Auſtrian inſect.

Tomentosa. Black, downy; antennæ thick at the baſe; the three firſt ſegments of the abdomen are ferruginous; the baſe and tip are black.

COCCINEA. Black; antennæ, jaws, tip of the abdomen, and ſhanks, ſcarlet; thorax with a tooth on each ſide behind; wings yellow, the hind margin brown.

SPINIPES. Black, hairy; wings yellow; the hind margin brown, with a black ſpot at the baſe of the upper pair; ſegments of the abdomen vary from two to four, which are yellow on the hind margin of each ſide. Its abode is not known.

GUTTATA. Black; with white lines and dots; wings pale yellow; legs rufous.

LEUCOMELLIS. Black; wings white towards the hind margin; firſt ſegment of the abdomen white on each ſide; the third with an ovate white ſpot on the back; the four hind-legs are rufous.

MELANOCHLORA. Black; abdomen ferruginous at the baſe. This is an European inſect.

TESTACEA. Black; legs and abdomen teſtaceous, the latter brown at the tip.

CASPA. The abdomen of this is black, with four yellow elevated bands; the three upper ones interſected by a triangular black ſpot. It inhabits near the Caſpian ſea.

SPHINCTER, in *Anatomy*, a name given to muſcles which ſurround, and have the office of cloſing, certain openings.

SPHINCTER *Ani*, the muſcle ſurrounding the extremity of the large inteſtine. See INTESTINE.

SPHINCTER *Labiorum*, the ſame as the orbicularis oris. See DEGLUTITION.

SPHINCTER *Iridis*. See EYE.

SPHINCTER *Œſophagi*. See DEGLUTITION.

SPHINCTER *Vaginæ*. See the deſcription of that canal under GENERATION.

SPHINCTER *Veſicæ*. See the deſcription of the urinary bladder under KIDNEY.

SPHINX, σφιγξ, in *Sculpture*, &c. a figure or repreſentation of a monſter of that name, famed among the ancients, now moſtly uſed as an ornament in gardens, terraces, &c.

It is repreſented with the head and breaſts of a woman, the wings of a bird, the claws of a lion, and the reſt of the body like a dog or lion.

It is ſuppoſed to have been engendered by Typhon, and ſent by Juno to be revenged on the Thebans. Its office, they ſay, was to propoſe dark enigmatical queſtions to all paſſers by; and, if they did not give the explication of them, to devour them.

It made horrible ravages, as the ſtory goes, on a mountain near Thebes, and could not by any means be deſtroyed, till after Œdipus had ſolved the following riddle: What animal is it that in the morning walks on four legs, at noon on two, and at night on three? The anſwer was, Man.

Among the Egyptians, the ſphinx was the ſymbol of religion, by reaſon of the obſcurity of its myſteries. And, on the ſame account, the Romans placed a ſphinx in the pronaos or porch of their temples.

Sphinxes were uſed by the Egyptians to ſhew the beginning of the water's riſing in the Nile: with this view, as it had the head of a woman and body of a lion, it ſignified that the Nile began to ſwell in the months of July and Auguſt, when the ſun paſſes through the ſigns of Leo and Virgo. Accordingly it was a hieroglyphic, which taught the people the period of the moſt important event in the year, as the ſwelling and overflowing of the Nile gave fertility to Egypt. Accordingly they were multiplied without end, ſo that they were to be ſeen before all their temples, and before all their remarkable monuments.

There are ſeveral of theſe ſtill to be ſeen; one in particular, near the pyramids, facing the ſecond pyramid on the eaſtern ſide, much ſpoken of by the ancients, being of a prodigious ſize, and cut out of the rock; the head and neck only appear at preſent, the reſt of the body being hid in the ſand. The top of its back only is viſible, which is more than 100 feet long. It is of one ſingle ſtone, making part of the rock on which the pyramids are placed. Its head riſes about twenty-nine feet above the ſand. This, according to Thevenot, is twenty-ſix feet high, and fifteen feet from the ear to the chin; but Pliny aſſures us, the head was no leſs than one hundred and two feet in circumference, and ſixty-two feet high from the belly, and that the body was one hundred and forty-three feet long, and was thought to be the ſepulchre of king Amaſis.

Some have ſuggeſted, that the well of the great pyramid led to this monſter, and that the prieſts reſorted thither at certain times to pronounce their oracles; alleging, that a hole placed at the top of the ſphinx's head anſwered their purpoſe; but this hole is only five feet deep, and communicates neither with the mouth nor with the inſide of the monſter. The Arabs, inſpired by Mahomet with a horror for all repreſentations of men and animals, have disfigured its face with arrows and lances. Some have urged, without ſufficient reaſon, that the ſphinx countenances the opinion that the Egyptians were black, the face of that ſtatue having been ſaid to reſemble the negro. The ſtatues of the Nile, it is ſaid, were made of black marble, in alluſion to his coming from Ethiopia. If the ſphinx was a ſymbol that had any relation to this ſubject, might not the negro face be given to it for a ſimilar reaſon? It would hardly have been thought neceſſary to explain why the figure of the Nile was black, if the complexion of the natives had been generally acknowledged of the ſame tinge.

The ſmall ſtatues of Iſis, &c. frequently found among the ruins of Egypt, are far from reſembling thoſe of the negro: the ſame obſervation is applicable to the figures in alto relievo and baſſo relievo, on the walls of Thebes, in the caverns of Gebel-el-Silſili, &c. Of the coloſſal ſtatues at Thebes, the features are too much damaged to be adduced in proof of the pretended fact.

The learned Mr. Bryant (Anc. Mythol. vol. iii. p. 532.) obſerves, that the ſphinx ſeems to have been originally a vaſt rock of different ſtrata; which, from a ſhapeleſs maſs, the Egyptians faſhioned into an object of beauty and veneration.

The Egyptians uſed this figure in their building; from them the Greeks derived it, and afterwards improved it into an elegant ornament.

SPHINX, the *Hawk-moth*, in *Entomology*, a genus of inſects of the order Lepidoptera, of which the generic character is as follows: Antennæ ſomewhat priſmatic, tapering at each end; the tongue is exſerted; feelers two, reflected; the wings are deflected.

The inſects of this genus, of which there are nearly two hundred ſpecies, fly abroad only in the morning and evening; they are very ſlow on the wing, and often make a humming kind of noiſe: they extract the nectar of flowers with the tongue. The generic name, ſphinx, is applied on account of the poſture aſſumed by the larvæ of ſeveral of the larger ſpecies, which are often ſeen in an attitude much reſembling that of the Egyptian ſphinx, *viz.* with the fore-parts elevated, and the reſt of the body applied flat to the ſurface.

The larva has ſixteen feet, and is pretty active; that of the *Zygæna*, a diviſion of this genus, is thick and flat, and covered with ſhort hairs; that of the *Seſiæ* is generally naked, unarmed, and thinner towards the head; the others have a ſharp, erect, ſtiff horn behind; the pupa is quieſcent: that of the zygænæ folliculate, and a little tapering forwards, the reſt naked and ſmooth; that of the ſeſiæ pointed at each end, of the others very obtuſe behind.

There are three diviſions of this genus; *viz.* A, of which the antennæ are ſcaly; feelers hairy; tongue ſpiral; B, in which the antennæ are cylindrical; the tongue is exſerted, truncate, and the wings entire; and C, in which the antennæ are thicker in the middle; tongue exſerted, ſetaceous. Of the principal ſpecies of theſe diviſions we ſhall proceed to give a brief account.

Species.

A. *Antennæ ſcaly; Feelers hairy; Tongue ſpiral.*

* **Ocellata.** Wings angular, lower ones rufous, with a blue eye. This is reckoned a very beautiful inſect; its upper wings and body are brown, the former finely clouded with different ſhades, while the lower wings are of a bright roſe-colour, each marked with a large ocellated black ſpot, with a blue interior circle and a black centre. This inſect proceeds from a green caterpillar of a rough or ſhagreen-like ſurface, marked on each ſide by ſeven oblique yellowiſh-white ſtreaks, and furniſhed, like the preceding, with a horn at the tail. It is chiefly found on the willow; retires under ground, in order to undergo its change into the chryſalis ſtate, in the month of Auguſt or September, and in the following June apppears the complete inſect.

Myops. Wings angular; upper pair with a yellow ſpot at the tip and poſterior angle; lower ones yellow, with a blue eye.

Quercus. Wings angular, indented, cinereous, with dark ſtreaks; lower ones ferruginous, white at the angle of the tail. This inhabits Germany. The larva is ſolitary and of a green colour, with oblique lateral ſtripes and rufous ſtigmata; pupa cheſnut, with rufous margin.

Lusca. Wings angular, duſky, with a black dot; lower ones black, with a fulvous band. It inhabits the South American iſlands. The upper wings are cinereous, with brown flexuous bands; lower wings cinereous at the angle of the tail, with a fulvous blotch; beneath it is a dull grey, and immaculate.

* **Populi.** Wings indented, reverſed, grey; upper pair with a white central ſpot; lower ones ferruginous at the baſe. This is found in England and many parts of Europe. It is figured by Donovan, and other writers on natural hiſtory. The larva is ſolitary, rough, green, with oblique white ſtripes on the ſides; the pupa is of a dull brown, but ferruginous behind.

* **Tiliæ.** Wings angular, with greeniſh clouds and darker bands; lower ones beneath yellow, teſtaceous. The larva is ſolitary, rough, green, with oblique red and yellow ſtripes on the ſides; the pupa is brown.

Pylas. Wings ſcalloped, indented, variegated; lower ones fulvous, yellow at the baſe, and black at the tip. It inhabits Surinam. Lower wings with a marginal black band, and contiguous ſmaller one; the edge itſelf is yellowiſh.

Cacus. Wings indented, black, with three approximate pale ſtreaks; lower ones are yellow, ſtriate with black. The abdomen is marked with cinereous and black belts.

Dentata. Wings indented; lower ones brown, with a white ſtreak; the abdomen is annulate with white. It is an Indian inſect. The head and thorax are blueiſh, ſpeckled with brown; the upper wings are blueiſh, with brown ſpecks and bands.

Alope. Wings indented, brown; lower ones yellow, tipt with black; abdomen black, with interrupted pale belts. This is found in divers parts of America. The larva of this ſpecies is tailed and glabrous, cinereous on the back, with a broad brown ſtreak before; ocellate in the middle, and ending in a black ſpot; pupa brown, with rufous rings and ſtreaks.

Jatrophæ. Wings ſlightly indented; lower one black, with a rufous baſe and hyaline band; the head is two-horned. The larva is green, with a moniliform tail; the pupa is brown, with an inflected cylindrical tail.

* **Atropos.** The wings of the inſects of this ſpecies are entire; the lower ones are yellow, with two brown bands; the abdomen is yellow, with belts. This is ſaid to be the largeſt and moſt remarkable, if not the moſt beautiful, European inſect of this genus. It is thus deſcribed by Dr. Shaw: the upper wings are of a fine dark grey colour, with a few ſlight variations of dull orange and white; the under wings are of a bright orange colour, marked by a pair of tranſverſe black bands; the body is alſo orange-coloured, with the ſides marked by black bars, while along the top of the back, from the thorax to the tail, runs a broad blue-grey ſtripe; on the top of the thorax is a very large patch of a moſt ſingular appearance, exactly repreſenting the uſual figure of a ſkull, or death's head, and is of a pale grey, varied with dull ochre and black. When in the leaſt diſturbed or irritated, this inſect emits a ſtridulous ſound, ſomething like the ſqueaking of a mouſe; and from this circumſtance, as well as from the mark above-mentioned on the thorax, it is held in much dread by the vulgar in ſeveral parts of Europe, its appearance being regarded as a kind of ill omen or harbinger of approaching fate. Reaumur mentions, that the members of a female convent in France were thrown into great conſternation at the appearance of one of theſe inſects, which happened to fly in during the evening at one of the windows of the dormitory. The caterpillar from which this curious ſphinx proceeds, is in the higheſt degree beautiful, and far ſurpaſſes in ſize every other European inſect of the kind, meaſuring ſometimes nearly five inches in length, and being of a proportional thickneſs; its colour is a bright yellow; the ſides are marked with a row of ſeven moſt elegant broad ſtripes or bands, of a mixed violet and ſky-blue colour; the tops of theſe bands meet on the back in ſo many angles, and are varied on that part with jet black ſpecks; on the laſt joint of the body is a horn or proceſs, not in an erect poſition, but hanging or curving over the joint in the manner of a tail, having a rough ſurface and a yellow colour. This caterpillar is principally found on the potatoe and the jeſſamine, which are its favourite food. It changes into a chryſalis in the month of September, retiring for that purpoſe deep in the earth; the perfect inſect emerging in the following June or July. Individuals have been obſerved to change into the chryſalis in July or Auguſt, and then produce the complete inſect in November, ſo that there appear to be two broods or races in a year.

The S. atropos is generally conſidered as a rare inſect, and as the caterpillar feeds chiefly by night, concealing itſelf during the day under leaves, &c. it is not often detected; yet from ſome ſingular circumſtances favourable to its breed, there are ſeaſons in which it is even plentiful, as was the caſe in the autumn of 1804, in which the caterpillar was ſo common in ſome counties, as to be prejudicial to the potatoe-plants, particularly in ſome parts of Cornwall and Surry.

"The alteration of form which the whole of the papilionaceous tribe undergo, and in a particular manner the changes of the ſphinx genus, afford a ſubject of the moſt pleaſing contemplation to the mind of the naturaliſt, and though a deeply philoſophical ſurvey demonſtrates that there is no real change produced in the identity of the creature itſelf, or that it is in reality no other than the gradual and progreſſive evolution of parts before concealed, and which lay maſked under the form of an inſect of a widely different appearance, yet it is juſtly viewed with the higheſt admiration, and even generally acknowledged as in the moſt lively manner typical of the laſt eventful changes."

Chionanthi. Wings variegated, with a white dot in the middle; abdomen with three pair of fulvous eyes. This is an American inſect. The antennæ are hooked, ferruginous, with a white ſhaft; lower wings blackiſh, ſpotted with white. Larva tailed, with yellow and black bands; the head and tail are red; the pupa is brown.

* Pinastri. Wings entire, grey, with three ſhort black lines in the middle of the upper pair; the abdomen is white, with black bands. The larva is tailed, and greeniſh, with a ferruginous dorſal line, a lateral yellow one, and ferruginous ſubocellar ſtigmata: the pupa is reddiſh-brown, with white eyes.

* Euphorbiæ. Wings entire, with two dark olive bands; lower ones with a black baſe, and marginal ſtreak; the antennæ are ſnowy. It is found in this country, and divers parts of Europe. Donovan has given a figure of it. The larva is black, dotted with white; it has a red line down the back, and lateral yellow ſpots; the pupa is brown, with black ſtigmata.

* Lineata. Wings greeniſh-olive, with a white band, croſſed with white ſtreaks; the lower ones are black, with a red band. It is generally deſcribed as having a greeniſh head, with a lateral white line; the thorax is marked with three double white ſtreaks; abdomen with a white line down the middle, and lateral black and white dots; the hind margin of the upper wings is of a purple colour. Beneath it is cinereous, ſpeckled with green.

* Celario. Wings entire, grey, with ſilvery-white ſtreaks; the lower ones are brown, with ſix red ſpots. The larva is tailed, brown, with two lateral pale lines, and two eyes on the neck, on each ſide; the pupa is brown before and reddiſh behind.

* Elpenor. Wings entire, with tranſverſe greeniſh-brown and red bands; the lower ones are red, with a black baſe. The larva is tailed, with brown ſpots and two blue eyes on each ſide of the neck; the pupa is grey before, behind brown, with darker ſtigmata.

* Porcellus. Wings entire, varied with yellow and purple; the abdomen is beneath ſanguineous, dotted with white. The larva is without a tail, brown, with three blue eyes on each ſide of the neck; the pupa is blackiſh.

* Convolvuli. Wings entire, clouded; lower ones ſlightly barred; abdomen with red, black, and white belts. This is found in our own country, and other parts of Europe. The larva is tailed, with oblique white lines on the ſides; the pupa is brown, with a reflected involute horn. The eyes of this inſect are ſaid to be ſlightly phoſphoreſcent.

* Ligustri, or Privet Hawk-moth. Wings entire; lower ones rufous, with three black bands; the abdomen is red, with black belts. The larva is tailed; in colour it is green, with oblique lateral ſtreaks, which are of a fleſh-colour before, and white behind; the pupa is brown; the tail is four-toothed.

Crantor. Wings entire, brown, ſpotted with black; lower ones red, edged with black. It inhabits India. The upper wings are marked with a pale ſpot at the baſe; the lower wings are ſpotted with black at the angle of the tail.

Labruscæ. Wings greeniſh, with a white dot on the lower ſurface of the upper pair; the abdomen is marked with five white dots at the ſides. This is an American inſect. The lower wings are marked with a black diſk, barred with a blue rufous ſpot at the angle of the tail. The larva is tailed, varied with brown and black; on the tail is a white poliſhed moveable dot.

B. *Antennæ cylindrical; tongue exſerted, truncate; wings entire. This diviſion is named*

Sesia.

Tantalus. Abdomen bearded, the third ſegment ſnowy. It inhabits Europe and India. The abdomen is marked with a white and rufous ſtreak; upper wings variegated with three white dots.

Hylas. Wings ſemi-tranſparent; abdomen bearded, green, with a purple belt. It inhabits China. The tail is marked with a white dot at the baſe; the ſides of the baſe are black.

* Stellatarum. Abdomen bearded, the ſides are varied with black and white; the lower wings are ferruginous. The larva is pale roſy, dotted with white; the tail blue, ferruginous at the tip; the pupa is pale, with a brown tip.

Pandora. Abdomen bearded, with fulvous ſpots on the ſides; the lower wings are ferruginous at the baſe, and tipt with black.

Fuciformis. Abdomen bearded, blackiſh, with a yellow band near the tail; wings diaphanous, with a darker brown border; beard of the abdomen black on each ſide. The larva is green, with a yellow lateral line; the horn is erect; pupa folliculate, black, with yellow ſtreaks before.

* Bombyliformis. Abdomen bearded, greeniſh, fulvous, with a black band; the wings are tranſparent, with a fine black edge.

* Apiformis. This ſpecies is of an aſpect at firſt ſight more reſembling that of a waſp, or hornet, than of a ſphinx, the wings being tranſparent, with merely a ſlight edging of brown, and the thorax and abdomen varied with black and yellow. The caterpillar inhabits the hollows of poplar, ſallow, willow, and lime-trees, feeding on the ſubſtance of the bark; changing to a chryſalis in April, and the fly appearing in the month of June.

* Crabroniformis. Wings tranſparent; abdomen yellow, with black belts; thorax black, with obſolete yellow ſpots; the head is black, with a yellow ring at the baſe. The larva is yellow; the pupa is reddiſh-brown. The male has two black bands near the baſe of the abdomen; the female is marked with irregular black lines.

* Culiciformis. Wings hyaline, with a black band and margin; the abdomen is bearded, with a fulvous belt; the antennæ are white before the tip.

* Tipuliformis. Wings tranſparent, with a black band and margin; the abdomen is bearded, black; the alternate inciſures are edged with yellow. This is figured by Donovan. The thorax has a yellow line on each ſide; tip of the upper wings marked with a brown ſpot. The larva is ſolitary, a little hairy, whitiſh, with yellow head and legs, and a darker dorſal line; the pupa is brown.

* Zonata. Wings tranſparent, with a black band and margin; the abdomen is bearded, black, with a ſingle belt. It is found in divers parts of Europe, as well as in this country. The head is marked with a thin red margin; on the thorax are two oblique lateral red lines.

Ichneumoniformis. Wings tranſparent, with a black margin and band, in which is a fulvous dot; the abdomen is marked with alternate black and white belts. It inhabits Auſtria.

* VESPIFORMIS. Wings tranſparent, with a black margin and band; abdomen bearded, black, the ſecond and laſt ſegments edged with yellow. It is found in this country, and many parts of Europe.

* CHRYSORRHÆA. Wings tranſparent, with a black margin and band; abdomen black, with four yellow belts; the beard is yellow, with a black line in the middle. This is an Engliſh inſect, and is figured by Donovan.

C. *Antennæ thicker in the middle; tongue exſerted, ſetaceous.*

ZYGÆNA.

* FILIPENDULÆ. Upper wings blue-green, with ſix red ſpots in pairs; the lower ones are red, with a greeniſh border. It is found in England, and other parts of Europe. The larva is flat, tailed, ſulphur-coloured, with four lines of black dots; the pupa is brown, but in the middle it is of a ſulphur-colour.

SEDI. Blue; upper wings with three connected red ſpots; the lower ones are entirely red. It inhabits ſouthern Ruſſia. The ſpots on the wings are ſurrounded with a yellow ring, and the lower wings with a fine black edge.

PHEGEA. Green-black; the upper wings are marked with ſix tranſparent dots, the lower ones with two; the abdomen with a yellow belt. It is found in many parts of Germany. The larva is brown; the head and legs are reddiſh; the back is marked with faſciculate white plumes.

CAFFRA. Black; wings brown, with five red dots; the lower ones are red, edged with brown. It is found in many parts of Africa. The head is black; feelers and orbits red; thorax black, with two red dots on each ſide; dots on the wings ſurrounded with a black ring.

CASSANDRA. Brown; abdomen with five blue ſpots on each ſide; tail, mouth, baſe of the thighs, and abdomen, ſcarlet.

ANDROMACHA. Black; wings hyaline, with a black margin and band; the tail is red. It inhabits America.

LETHE. Wings black, with two yellow ſpots; abdomen with red, black, and blue belts, and a white one. This is an African inſect.

PECTICORNIS. Browniſh; wings violet, with two white bands a little interrupted; the collar is red. It is found in South America.

SYPILUS. Wings black; upper pair with an interrupted teſtaceous band; lower ones teſtaceous at the baſe; the abdomen is dotted with blue. It inhabits different parts of America. The abdomen is black, with teſtaceous belts at the baſe; the tip is dotted with blue.

CAPISTRATA. Wings black, with two tranſparent bands on the upper pair; the lower ones have a tranſparent diſk; the abdomen is red and black on the back. It inhabits America.

COLUMBINA. Wings tranſparent, with a black ſpot, and border marked with red. It inhabits South America. The antennæ are pectinate; the head is black, with two red dots; the thorax is marked with white lines; the abdomen is black, the firſt ſegment is red, the others are marked with white and red belts.

CAUDATA. Wings yellow, hyaline, tipt with brown; body ſpotted with gold. This inhabits South America.

DIPTERA. Wings brown; upper pair with five tranſparent ſpots; lower ones very ſhort, with a yellow ſpot. This inhabits the Eaſt Indies.

TIBIALIS. Upper wings brown, lower ones hyaline; hind-legs long and very hairy. It inhabits Africa.

CAPYS. Black; upper wings tipt with white. Inhabits Surinam.

* STATICES. Upper wings green-blue; lower ones brown. Inhabits divers parts of Europe, as well as this country.

ACHARON. Blue; wings brown; tail rufous. It inhabits New Holland.

STYX. Body and wings blue; thorax rufous. It is found in Africa.

THOAS. Upper wings brown; lower ones black, with ſemitranſparent diſk; collar red.

SPHINX, a name given by Reaumur to a very ſingular ſpecies of caterpillar, deſcribed in the ſecond volume of his Hiſtory of Inſects.

The reaſon of the author's having given it that name is, that when it is not eating it erects its head, and with it more than a third part of its body, into a perpendicular ſituation upon the leaf on which it was before laid all along; it keeps itſelf a long time in this ſituation, looking around it with a ſeeming air of fierceneſs. There is alſo a ſeries of broad belts upon the body, which contribute ſomething towards its reſemblance to the figure of that imaginary monſter.

This caterpillar has a horn on the hinder part of its body, which ſeems to be of no ſort of uſe, but merely a trouble to the creature. It is hollow, and incloſes, in the manner of a ſheath, the new horn which is to appear when the creature changes its ſkin. This the author found to be the caſe, by cutting it ſeveral times, and always finding within it the new horn cut off alſo at the ſame place, and had often obſerved the great difficulty the animal had in changing its ſkin, when it came to the horn.

SPHINX, *Simia*. See SIMIA.

SPHONDYLIUM, in *Botany*, σφονδυλιον of Dioſcorides, the Cow-parſnip. See HERACLEUM.

SPHONDYLOCOCCUS, ſo called, by Mitchell, from the whorled appearance of the berries, is the Linnæan CALLICARPA. See that article.

SPHONDYLUS, in *Ichthyology*, a name given by Pliny, and others of the old authors, to a peculiar ſpecies of the ſyngnathus, or *acus Ariſtotelis*. It is the ſpecies, called by Artedi *ſyngnathus corpore medio hexagono cauda pinnata;* and by other authors the *acus ſecundæ ſpecies;* and by Bellonius and Geſner *typhle marina*.

SPHONDYLUS is alſo uſed by ſome authors, for the ſtones or bones found in the head of a mullet.

SPHRAGIDE, or *Lemnian Earth*, in *Mineralogy*, a name given by Werner to a ſubſtance nearly reſembling fullers'-earth, found in the iſland of Lemnos, in the Mediterranean. It is of a greyiſh or yellowiſh-white colour; it has a dull aſpect and a meagre feel, in which reſpect it differs from fullers'-earth; it adheres ſlightly to the tongue, and falls to pieces when immerſed in water. The conſtituent parts of this mineral, as given by Klaproth, are,

Silex	66
Alumine	14.50
Magneſia	0.25
Lime	0.25
Soda	3.50
Oxyd of iron	6
Water	8

This earth is dug but once a year, on the 15th of Auguſt, in the preſence of the clergy and magiſtrates of the iſland, after the reading of prayers. The clay is cut into long pieces of an ounce weight, and each of them is afterwards ſtamped with a ſeal, having on it the Turkiſh name of the mineral. It is in great repute in the Eaſt, as an antidote againſt poiſon and the plague; and even in the time of Homer was valued on the ſame account. It was then ſtamped as at preſent, and none but prieſts were allowed to handle it. Severe puniſhments were alſo inflicted on thoſe who preſumed to dig for it at any other but the ſtated period. The geological poſition of this mineral is unknown. See Fullers'-*Earth*, and Lemnian *Earth*.

SPHRAGIS, the ſeal-ſtone, a name given by ſome authors to the ſingle joints of the aſteriæ, when found looſe, not joined into a column. See Star-*Stone*.

Sphragis is alſo uſed by ſome of the old Greek naturaliſts, to expreſs the ſpots on the back and ſides of a panther.

The ſkin of this creature is of a pale colour, and theſe ſpots are all dark and round, and look like ſo many regular impreſſions of a ſeal, whence the name ſphragis.

The Romans called any thing that was variegated in this manner *pantherina;* and we meet with the phraſe *menſæ pantherinæ*, uſed to expreſs tables found of ſome wood, which was variegated with round ſpots, in the manner of thoſe ſphrages on the back of the panther.

SPHYGMICA, in *Medicine*, a term uſed by ſome for that part of the judgment of a phyſician, which regards the differences of the σφυγμος, or *pulſe.*

SPHYRÆNA, in *Ichthyology*, a name by which ſome authors have called the *ſudis*, or *lucius marinus*, the ſea-pike.

Sphyræna *Altera*, a name given by Appian, and ſome other of the old Greek writers, to the *eſox*, or common pike.

SPICA, in *Botany* and *Vegetable Phyſiology*, a ſpike, is a mode of inflorеſcence, very general in the natural order of *Orchideæ*, and frequent among many other tribes of plants. It is compoſed of ſeveral flowers, ranged along a common flower-ſtalk, without any partial ones, each individual flower being ſeſſile. The ſpike is generally erect at the time the flowers expand, and the latter are leſs crowded than in a Racemus. See that article, and Inflorescence.

Spica *Bandage*, in *Surgery*, is a kind of bandage thus called from its interſections, which are ſuppoſed to reſemble an ear of corn. It is either ſimple or double. The ſimple ſpica, applied to the clavicle, when fractured near the ſhoulder, conſiſts of a ſimple band, about five ells long, and three fingers breadth, rolled up either with one or with two heads. The double ſpica, which is uſed when the oſſa humeri of each arm are diſlocated, is a band about ſeven or eight ells long, and three or four fingers breadth, rolled up with two heads: the middle is fixed under the axilla, and the two heads croſs each other upon the ſhoulder, and go over the breaſt and back to the oppoſite axilla; here they croſs again, and then riſe up over the other ſhoulder as before, from whence they go acroſs the breaſt, and back again to the left axilla, where they began, forming an X, by traverſing each other upon the ſternum and back. See Bandage.

Spica *Virginis*, a ſtar of the firſt magnitude in the conſtellation Virgo.

SPICCATO, Ital., diſtinct, detached, ſeparated, in *Muſic*, as if half the note were cut off by a reſt. This term is nearly of the ſame ſignification as *ſciolto* and *ſtaccato;* except that, on the violin, when ſpiccato is written over or under a group of notes, they are to be touched lightly with the vibration of one bow; and ſciolto and ſtaccato paſſages and movements require a ſtrong bow to every note.

SPICE, any kind of aromatic drug, that has hot and pungent qualities: ſuch are pepper, nutmeg, ginger, cinnamon, and cloves. Some alſo apply the word to divers other medicinal drugs brought from the Eaſt; as ſenna, caſſia, frankincenſe, &c. See each under its proper article.

Spice, *All*. See Pimento.

Spice-*Wood*, in *Botany*, a ſpecies of *Laurus;* which ſee.

Spices, *Garbler of*. See Garbler.

SPICHEROEG, in *Geography*, a ſmall iſland in the German ſea, near the coaſt of Frieſland. S. lat. 53° 43'. E. long. 7° 32'.

SPICULUM, in *Roman Antiquity*, a kind of weapon which ſome will have to be the ſame with the haſta, or ſparus.

SPIDER, in *Entomology*, is the trivial name by which the large genus Aranea is generally known: under that term we promiſed to give an account of the ſpecies in their alphabetical order; this, from a change in the plan, having been neglected, we ſhall take the opportunity which the word *ſpider* affords, of enumerating thoſe ſpecies in as brief a manner as the ſubject will allow. We ſhall, however, be under the neceſſity of giving in this place the generic character, which is as follows: Mouth with ſhort horny jaws, the lip rounded at the tip; two feelers, incurved, jointed and very ſharp at the end; thoſe of the male are clavate; they have no antennæ, generally eight eyes, but ſometimes only ſix. Eight legs; the abdomen is ovate, villous, furniſhed at the tip with textorial papillæ.

Much intereſting matter on the ſubject of ſpiders will be found in the article Aranea; here it may be obſerved, that in every ſtage of their exiſtence, theſe animals prey with the utmoſt ferocity upon all other inſects that they can overcome, and even upon one another: from the papillæ at the end of the abdomen, they throw out at pleaſure a number of fine threads, which they unite in various ways, for the purpoſe of entangling their prey. They every year caſt off their old ſkin, which is performed by ſuſpending themſelves in ſome ſolitary corner, and creeping out of it. The younger ones have the power of flight, and in the autumn mount in the air to a great height; to perform which, they probably aſcend ſome lofty eminence, and are wafted about by the winds, filling the atmoſphere with their fine threads. The ſpider is infeſted by the *ſphex* and *ichneumon;* which ſee reſpectively.

Gmelin has enumerated more than a hundred and twenty ſpecies of this genus, which are ſeparated into diſtinct ſections, according to the number and poſition of their eyes.

Species.

A. *Eyes placed* ∷∷

* Extensa. Abdomen long, ſilvery-greeniſh; legs longitudinally extended. This ſpecies is found chiefly in the woods of this country, and other parts of Europe. The head, thorax, and legs, are reddiſh; the abdomen is greeniſh down the back; the firſt pair of legs very long; the third very ſhort.

Pallens. Pale teſtaceous; mandibles ferruginous, with black claws. It inhabits the American iſlands.

Lobata. Abdomen ovate, lobed, white, with double brown lines at the tip. It inhabits the Cape of Good Hope.

Longimana. Ferruginous; abdomen long, cylindrical, brown. It inhabits Jamaica. The fore-legs very long, hence its ſpecific name; third pair very ſhort.

Regia. Villous, cinereous, with a yellow band on the front; the legs are ſpinous. It inhabits Tranquebar, and is large.

Virescens. Green, with a black cylindrical abdomen; the fore-legs very long. It inhabits Zealand.

CANCRIFORMIS. Abdomen globular, gibbous, with ſix ſpines round the margin. This is found in Jamaica.

VENATORIA. Gloſſy-black, with a blackiſh hairy abdomen. This is an American inſect, which ſpins a large cylindrical web under ground, which is covered with a lid; its bite is very painful, and frequently occaſions fever, and even delirium, which are however quickly removed by ſudorifics.

13-GUTTATA. Black; abdomen rounded, and ſpotted with red. This is an Italian inſect. Its bite is ſaid to be very pernicious; it preys on crickets, which it encompaſſes and entangles in a web.

* LATENS. Black; abdomen greyiſh, with a black interrupted dorſal line. It inhabits England, and ſecretes itſelf under a ſmall web on the under ſurface of the leaves of plants, and is a ſmall inſect.

SIGNATA. Greeniſh; ſides of the thorax black; abdomen with two black lines. It inhabits Kiel, in Germany.

MACTANS. Abdomen ovate, black, with a ſcarlet dorſal line. This is an American inſect. There is a variety whoſe abdomen is diſtinguiſhed with two pair of ſcarlet dots, and a tail.

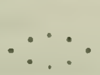
CICUREA. Pale red, with a cinereous ovate abdomen. This inhabits Germany, and is found in houſes.

BICORNIS. The inſects of this ſpecies are yellowiſh; the abdomen is depreſſed, with ſix impreſſed dots; the head is two-horned. It inhabits Tranquebar.

NIGRITA. Black; abdomen with two teſtaceous dots beneath. It inhabits Saxony, and is middle-ſized.

CORNUTA. Brown; abdomen oval, cylindrical, above yellowiſh-white, with four pair of impreſſed dots and four parallel grey lines behind. This is found in America. It is about the ſize of a man's finger; the legs are long; the thorax truncate on each ſide, and ending in two ſmall horns behind.

B. *Eyes placed*



* GLOBOSA. Black; abdomen globular, with crimſon ſides. It is found in the woods of England and other European countries. The body is very ſmall: the abdomen with an interrupted white band in the middle; the legs are black; the hind ones are the longer.

C. *Eyes placed*

HORRIDA. Abdomen nearly triangular, the tip truncate and obtuſe, the four front legs are the longer. It inhabits Germany, under the leaves of plants, and has a retrograde motion; it is of a ſingular formation.

MAXILLOSA. Ferruginous, with a greeniſh abdomen; the legs are pale; the mandibles large and projecting. It inhabits the iſland of Santa Cruz.

SMARAGDULA. Green; abdomen paler, with a green dorſal line at the baſe. It inhabits France.

LATRO. Thorax villous, cinereous; abdomen acute, black, with ferruginous ſpots. It inhabits America.

* VIATICA. Brown, with a roundiſh flat obtuſe abdomen; four hind-legs very ſhort. It inhabits Europe, in gardens and meadows, and is ſmall.

* DOMESTICA. Abdomen ovate, brown, with five black and nearly contiguous ſpots, the anterior ones larger. It inhabits Europe, is very common in houſes and about windows; it preys chiefly on flies.

DORSATA. Green; abdomen brown on the back. It inhabits Kiel.

TESTACEA. This is teſtaceous; the abdomen is ſubglobular, dull greeniſh. It is found in divers of the South American iſlands.

* TRILINEATA. Abdomen ovate, whitiſh, with three longitudinal lines of blackiſh dots.

IMPRESSA. Black; abdomen ovate, with ſix impreſſed dots, and two yellow dots beneath. It inhabits Norway, on rocks.

* LÆVIPES. Abdomen rhomboid, depreſſed, and ſpotted with black; the legs are extended and variegated. It is found on walls in this country, and other parts of Europe.

TRICUSPIDATA. Greeniſh; abdomen white, with a reddiſh tail. It inhabits Saxony. Head, thorax, and legs, greeniſh; eyes, eſpecially the latter ones, elevated.

D. *Eyes placed*

ARGENTATA. Abdomen white, and brown behind; the margin ſix-toothed. It inhabits America and the Eaſt Indies. Thorax ſilvery, the margin of the abdomen is armed with three ſtrong ſpines on each ſide.

E. *Eyes placed*

FASCIATA. Silvery; abdomen with a yellowiſh band; legs annulate with brown. It inhabits Madeira.

* ANGULATA. Abdomen ovate, the ſides angular and acute on the fore-part; the thorax has an excavated centre. It inhabits our own country, and divers other parts of Europe, in trees, and ſpins a web, which is perpendicular in its poſition, and which varies very much in colour.

* DIADEMA. Reddiſh-brown; abdomen gibbous, and marked with white drop-ſhaped ſpots in the form of a croſs. This is found in our own country in trees, and is reckoned a very beautiful inſect. The body varies much in colour from a darker to a lighter reddiſh-brown; the legs are annulate with brown.

MARMOREA. Brown; abdomen ovate, varied with white and brown; found chiefly on the European continent. Spins its web on the ground; the legs are yellow, annulate with brown.

RETICULATA. Abdomen globular, reticulate, above purpliſh, clouded with brown, found chiefly in the gardens in Europe.

* CUCURBITINA. Abdomen ſubglobular, yellow, with a few black dots. It belongs to this and other European countries, is found in trees, and ſpins a lax web.

CALYCINA. Abdomen globular, pale yellowiſh. This is an European inſect, and is found in the calyces of flowers from which the coral has fallen, and faſtens on bees and flies that come to extract the nectar.

8-PUNCTATA. Abdomen roundiſh, yellow, with four black raiſed dots on each ſide; tail rufous. It inhabits Sweden, and is thought by ſome writers not to belong to this diviſion.

BI-PUNCTATA. Abdomen globular, black, with two hollow dots. It is found chiefly in windows in European countries.

RIPARIA. Abdomen ovate, black-bronze; tail pale yellow, and two-horned. It inhabits Sweden, on gravelly ſhores.

* QUADRATA. Abdomen ſubglobular, yellowiſh-rufous, with a white line at the baſe and four ſpots. It inhabits the woods of Europe. It is ſomewhat leſs than the diadema, and perhaps only a variety of it.

LITURATA. Teſtaceous; abdomen pale black, with a white margin and marks. Inhabits France.

QUADRI-PUNCTATA. Abdomen oblong; the back black and flat, with four excavated dots. It inhabits Europe, in houſes.

Militaris. Black; with four ſpines, the hind ones longer and ſpreading. This is an American inſect, as are the three following.

Spinosa. Back with eight ſpines, the two hind ones ſpreading; abdomen beneath conic. The body is brown, and of a triangular ſhape.

Aculeata. Back with ſix ſpines, the hind ones ſpreading.

Tetracantha. Abdomen globular, with four ſpines round the margin. The head and thorax are ferruginous; abdomen with impreſſed dots at the baſe.

Hexacantha. Abdomen tranſverſe, with ſix ſpines round the abdomen. This inhabits Jamaica, and is ſuppoſed to be the ſame, or at moſt a variety of the cancriformis.

Fornicata. Sides of the abdomen a little vaulted, with two ſpines, the poſterior one longer. It is found in New Holland. A ſpecimen exiſts in the muſeum of ſir Joſeph Banks.

* **Labariuthica.** Abdomen ovate, brown, with a whitiſh pinnate line. It ſpins an horizontal web on the ground, with a cylindrical cavity.

Quadri-lineata. Abdomen roundiſh, yellow, with a purpliſh line on each ſide, and four dots. It inhabits Sweden. It is hyaline, with a yellow front.

* **Rediusita.** Abdomen oval, pale yellow, with a crimſon oval crown or ring on the back. It is found in gardens. The legs are long, white, and tranſparent.

Corollata. Abdomen oval, black, with a white oval ring on the back. It inhabits Europe, on plants.

* **Montana.** Abdomen oval, white, with grey ſpots. It inhabits Europe, on trees. The thorax and legs are pale; the fore-legs are long and extended.

Sanguinolenta. Abdomen ovate and ſcarlet, with a longitudinal black line. It inhabits Spain.

Nigra. Abdomen ovate, and ſcarlet above. This is an inhabitant of Calabria.

Notata. Abdomen ovate, brown, with white tranſverſe curved lines. Found in divers parts of Europe, as are the three following.

Rufipes. Abdomen brown; legs rufous. Found chiefly on nettles.

Nocturna. Abdomen black, with two white dots, and a white lunule at the baſe.

Sex-punctata. Abdomen oblong, with three pair of excavated dots.

Palustris. Thorax and abdomen with a ſnowy line on each ſide. Found in the reedy marſhes of Germany. The tip of the thorax before the eyes ends in a white line.

* **Aquatica.** Brown; abdomen ovate, cinereous; the back brown, with two impreſſed dots. This is found in our own and other European countries, in freſh-water lakes, where it dives to the bottom in ſearch of food, within a globule of air formed by itſelf. It takes up its winter quarters in a forſaken ſhell, the aperture of which it cloſes up with a web. Its jaws are large, ſtrong, black, with ſcarlet nails.

Obscura. Abdomen ſubconic, duſky, with a whitiſh dorſal line. It inhabits France, in woods, as does the next.

Scalaris. Thorax teſtaceous; abdomen ſnowy on the back, with an oblong indented ſnowy ſpot at the tip.

Trigutta. Yellowiſh; abdomen black, with three white ſpots. Found in Alſace.

Scorpiformis. Black; abdomen whitiſh, with two black lines; fore-legs very long. Found in gardens at Leipſic. It is ſmall and retrograde.

* **Carnifex.** Ferruginous; abdomen grey, with a dorſal line. It inhabits England.

Flavissima. Abdomen oblong, of a fine rich yellow colour, and ſmooth. Found in Egypt.

Bimaculata. Abdomen roundiſh, cheſnut-brown colour, with two white dots. It inhabits Europe, and is leſs than a flea.

Truncorum. Black, with white dots on the back. It ſprings to a great diſtance on its prey. It is an European inſect, and found on walls and the trunks of trees.

Rupestris. Abdomen with a black ſpot, edged with red, and white in the middle. It ſprings on its prey, and is found chiefly on old walls.

Virescens. Abdomen oblong, yellow-green, with lateral white lines.

Spinipes. Pale, with ſpinous legs. A variety has ſpinous legs, with ferruginous joints. Found in divers parts of Europe.

Opilionoides. Grey, with very long and extremely ſlender legs. It inhabits Germany and France; ſpins a very lax irregular web, the threads croſſing each other; and is gregarious.

Osbeckii. Pale yellow; abdomen with impreſſed dots in pairs, with an odd one; the fore-legs are longer. It inhabits Auſtria, as does the next.

Wilkii. Varied with black and grey; legs cinereous, annulate with black; the hinder ones are ſhorter.

Speciosa. Thorax grey, with two brown ſpots; the abdomen is oval-oblong, with tranſverſe black curves; beneath it is reticulate with black, with two yellow bands. It inhabits Calabria and Siberia, and is domeſticated in the houſes of the Coſſacks. It is a very beautiful ſpecies.

F. *Eyes placed* : : . . . .

Clavipes. Abdomen oblong, yellow, dotted with white; all the ſhanks, except the third pair, clavate and hairy. It inhabits South America, in trees and out-houſes; ſpins a ſtrong ſpreading web, and is a beautiful ſpecies.

* **Saccata.** Abdomen ovate, ruſty-brown. This is found in gardens, and it carries its bag of eggs behind it.

Fumigata. Abdomen ovate, brown, with two white dots at the baſe. This is found in Sweden. It lives in meadows, and watches before the neſts of larvæ, which it catches as they come out, one after another, and ſucks out their vitals.

G. *Eyes placed* : . . . :

Fimbriata. Black; abdomen oblong, with a white line on each ſide. It is found in many parts of the continent of Europe, in reedy marſhes.

* **Dorsalis.** Black; thorax compreſſed, with a white dorſal line. It is common in England. The abdomen is ovate, whitiſh at the baſe; the legs are livid.

Sanguinolenta. Black; abdomen red, with a black dorſal line. It is found in divers parts of Europe, and ſprings on its prey.

Pupillata. Teſtaceous; abdomen brown on the back, with ſubocellar fulvous ſpots. It inhabits China.

* **Scenica.** Black; abdomen ſubcylindrical, with three ſemicircular white lines on each ſide. It ſprings on its prey. It inhabits this and other countries of Europe, on old walls and windows. The body is covered with ſilvery hair; the legs are ſhort, hairy, black and white.

Fulvata. Black; hind margin of the thorax fulvous; abdomen with three fulvous bands. It inhabits Cayenne.

Pubescens. Abdomen ovate, brown, with four cinereous ſpots, the hind ones larger. It inhabits Leipſic.

Cinerea. Cinereous; abdomen brown on the back, with eight cinereous dots. It is found on the ſhores of the Baltic.

Trilienata. Brown; thorax with a paler margin, and lateral dorſal line; abdomen ovate, cinereous; beneath brown. It inhabits Naples.

Tarantula. Abdomen with triangular black ſpots on the back; the legs are ſpotted with black. This is found in the ſouthern parts of Europe, but chiefly in Italy, and likewiſe in Barbary, in cool caverns, and is the inſect whoſe bite was long ſuppoſed to be curable by muſic only. It is generally admitted to be partially poiſonous, but never fatal. See Tarantula.

H. *Eyes placed* ˙ ˙ . : : .

Avicularia. Thorax orbicular, convex, with a tranſverſe central excavation. Found among trees in South America, where it preys upon larger inſects, and even upon ſmall birds, dropping into their neſts, and ſucking their blood and eggs. It is ſaid to be of ſo enormous a ſize, that its fangs are equal to the talons of a hawk; and its eyes are capable of being ſet in the manner of glaſſes, and uſed as microſcopes.

I. *Eyes placed* . . : : . .

Pulchra. Oval-oblong; thorax villous, white; abdomen and legs black, with yellow bands. It inhabits Helvetia.

K. *Eyes placed* : : : :

Goezii. Black; abdomen ovate; front white. It ſprings on its prey, and is uſually found in the woods of Vienna. The abdomen is marked with two impreſſed dots.

L. *Eyes placed* : : . . . .

Truncata. Grey, ferruginous, ſlightly clouded; thorax globular, and ſlightly heart-ſhaped; the abdomen is ſomething triangular, and marked with an obſolete longitudinal croſs. It is found in Germany, on oak and other trees.

M. *Eyes placed* ˙ ˙ ˙ : . . . :

Conica. Abdomen ovate, obſcurely conic behind, varied with brown and whitiſh, and black beneath. This, like the laſt, is found in the woods of Germany, and ſpins a labyrinthical web.

N. *Eyes placed* : · · · · · .

Albifrons. Hairy; body ovate, and variegated with black and cheſnut-brown. It inhabits Luſace.

O. *Eyes placed* ˙ ˙ ˙ ˙ . .

Taurus. Abdomen flat, with two very long curved ſpines. Found chiefly at St. Domingo.

Arcuata. Brown; abdomen with ſix ſpines, the middle ones curved, and ſix times as long as the body. This is found in the Eaſt Indies, and is a ſmall inſect.

Maculata. Thorax ſilvery; abdomen cylindrical; legs very long and black. It inhabits China.

Pilipes. Brown; abdomen cylindrical, with ſilvery lines; legs very long and hairy. It inhabits the Eaſt Indies, and is a large inſect.

Myopa. Greeniſh; abdomen red on the back, with a few black dots; the ſides are yellowiſh. It inhabits Kiel. This is a beautiful inſect; the mandibles are tipt with black; the thorax with two darker lines; abdomen ovate, pubeſcent; textorial papillæ tipt with black; legs long, pale greeniſh; the fore-ſhanks tipt with black.

Longipes. Black; abdomen cylindrical, brown, with ſix impreſſed dots; the legs are very long. It inhabits Auſtralaſia.

Rufipes. Ferruginous; abdomen ovate, pale cinereous; legs rufous. It inhabits Morocco.

* Senoculata. Abdomen greeniſh, with black dots, and a yellow line on the ſides. It is found in gardens and on walls.

Scopulorum. Abdomen brown, with a pinnate white dorſal line. It inhabits Norway, and is found on rocks.

Lusea. Pale; abdomen ſilvery, with black branched lines. It inhabits Tranquebar.

Parallela. Brown; ſides of the thorax and abdomen white; mandibles projecting and parallel. It inhabits the American iſlands.

Scrofa. Hairy, brown; abdomen ſemiorbicular; mandibles black, exſerted, and hooked at the tips. It inhabits under ground at Chili, and is about the ſize of a pigeon's egg.

Bicornis. Abdomen two-horned. It inhabits Siberia.

Caspia. Thorax ſubglobular; abdomen oblong, varied with yellow and black bands. This ſpecies inhabits the deſerts of Ural, and is regarded by the Calmucks as venomous.

Argentea. Thorax orbicular, depreſſed, white, with two black fillets; abdomen is ovate, lobed, ſilvery, with two pair of dots in the middle, and four rows behind. It inhabits the deſerts of Ural, and is accounted poiſonous by the Calmucks. It ſpins a perpendicular web.

P. *Number and Poſition of the Eyes unknown.*

Nobilis. Thorax orange, with ſix black ſpots; abdomen yellow, with ſeven black ſpots. It inhabits Sumatra.

Calceata. Hairy, grey; legs with two black ſpots at the tip above; beneath ſilky, with a green gloſs. It inhabits Guinea, and is a very large inſect.

* Holosericea. Abdomen ovate-oblong, ſilky, livid brown, with two yellow tubercles beneath.

Spinimobilis. Abdomen roundiſh, yellowiſh-brown, with four rows of blackiſh dots; thighs with black moveable ſpines. This is found at Surinam.

Cruentata. Black, with a yellow band at the baſe of the abdomen; the breaſt is of a deep red. It inhabits Brazil.

Sex-cuspidata. Brown; back of the thorax ſix-toothed, with a lateral fulvous ſpot. It inhabits the Cape of Good Hope.

Hirtipes. Black; feelers and legs hairy, and pale teſtaceous. It inhabits Cayenne.

Tribulus. Head three-toothed on the fore-part, abdomen covered with numerous ſpines. It inhabits the Cape of Good Hope.

Elegans. Black, with two white curves on the fore-part of the thorax, and a white dorſal line on the abdomen. This is an American inſect.

Ocellata. Pale; abdomen clouded, with a black ring; the thighs are marked with three doubled ocellate ſpots. It inhabits China, and is the ſize of the tarantula.

Alba. White; abdomen with five impreſſed dots; two-horned and depreſſed at the baſe, and globular at the tip. It inhabits Siberia, under the bark of trees.

The eggs of ſome ſpiders are a very pleaſing microſcopic object; they are round at one end, and flattiſh at the other, with a depreſſion in the centre of the flattiſh end, and a yellowiſh circle round it. The colour of theſe eggs is a pearly or blueiſh-white, and when the young ſpiders hatch, they come out in their perfect form, and run about very nimbly.

The female ſpider depoſits her eggs, to the number of five or ſix hundred, in a bag compoſed of her own web, which ſhe either carries under her belly, or hides in ſome very ſafe receſs. Philoſ. Tranſ. N° 272.

The young ſpiders are always very beautiful objects for the microſcope. The current of the blood may be eaſily diſcovered in their legs, and part of their bodies; and many other curious particulars occur in their diſſection. There are two or three ſpecies of this animal particularly worthy the attention of the curious in microſcopic diſcoveries. 1. A little white field ſpider with ſhort legs. This is found plentifully among new hay, and its body appears like white amber with black knobs, out of which grow ſhort but ſharp prickles. The eyes of theſe may be very diſtinctly ſeen, being very briſk and lively, and ſome have ſix, ſome eight of them; each eye has a pupil of a violet blue, which is beautifully clear and tranſparent, and is ſurrounded by a circle of pale yellow. 2. The wandering, or hunting ſpider, that ſpins no webs, but runs and leaps by fits. This has two tufts of feathers fixed to its fore-paws, which make a very beautiful appearance before the microſcope. The variety and beauty of colouring alſo, all over this little creature, afford a very pleaſing ſight. 3. The *long-legs*, or ſhepherd ſpider. This is a moſt wonderful creature: it has two fore-claws at a great diſtance from the head, tipped with black, like thoſe of a crab, and opening and ſhutting like the ſcorpions; theſe are ſerrated or indented on their inſide. When all the legs are cut from this ſpider, and it is examined by the microſcope, it will be ſeen that the protuberance on the top of its back is furniſhed with two fine black eyes. Power's Microſ. Obſ. p. 13. Hook's Micrógr. p. 200.

The venom of many kinds of ſpiders is greater than uſually ſuppoſed: we have, in the Philoſophical Tranſactions, an account of a perſon in New England who was bitten by a ſmall ſpider a little above his ankle; he perceived the creature biting, and cruſhed it to death upon the wound, between his ſtocking and his leg; in half an hour he felt a pain in that leg, which in another half hour extended itſelf to the groin, and at the ſame time he had a creeping pain in the calf of his other leg; and in a quarter of an hour after this it affected his ſtomach, his back, and his head. The pains were not conſtant and fixed, but erratic, and very acute, and his pulſe was extremely low and heavy. He was relieved, by taking internally ſpirit and ſalt of hartſhorn in viper-wine, and applying a cataplaſm of garlic to the part, and in three or four days wholly recovered.

Boccone mentions a ſpecies of large ſpider, common in the iſland of Sardinia, whoſe bite proves mortal within the ſpace of a few hours; the whole body uſually ſwells almoſt immediately, in conſequence of this bite. The cure is performed by oil of olives, in which the creature is infuſed over the heat of a ſtove. This is a medicine they always keep ready in the houſe, and while they uſe this externally, they give large doſes of Venice treacle inwardly, diſſolved in ſtrong wine: but many die of this bite, either from the want of power in the remedies, or from their being uſed too late.

There is hardly any ſubject on which there has been a greater difference of opinion than the ſuppoſed poiſon of ſpiders. To the obſervations that occur in this article and alſo under Aranea, we ſhall here add ſome further remarks, with which we are furniſhed by Dr. Amoureux, jun. a late French writer. Our ſpiders in France, ſays this author, (in his "Notice des Inſectes de la France reputés venimeux,") are in general rather ugly than formidable. If any are ſuſpected of being poiſonous, it ought not to be the domeſtic ſpider with long claws, aranea phalangiodes, Linn., nor the mower of the fields, phalangium opilio, Linn., the only kinds of the phalangia mentioned by Geoffroy; nor the maſon ſpider, nor the orange-coloured ſpider, and that entirely white aranea viatica, and the aranea citrina, Linn., found commonly among vegetables or fruit, and chiefly grapes, nor many others, which we ſee daily, and of which we have no cauſe to complain. Swammerdam did not believe that the ſpider emitted through the ſtings or darts with which it pierces the animals whoſe blood it ſucks, a venomous liquor. Liſter, on the other hand, who ſays that he had certain proofs of ſpiders being venomous, expreſſed the poiſon from theſe inſtruments. Leuwenhoeck alſo advances, that the venom of the ſpiders is contained in the cavity of the ſharp pincers which proceed from the mouth of the inſect. Others have ſaid that theſe forceps are not hollow, but that the venom proceeds from a ſmall trunk which iſſues from the mouth at the moment when the inſect ſeizes its prey. (See Aranea.) Although it be a certain fact, that many ſpiders, and perhaps all of them, throw out from their mouth a certain liquor, with which they moiſten their prey, we may reſt aſſured, ſays Amoureux, that our ſpiders have nothing in them of a venomous nature; and this is proved by their being often touched without danger, and by their being eaten without injury. Redi ſaw people who ate ſpiders, and from the experiments which he made, he does not believe them to be poiſonous. Clark and Roeſel maintain, that ſpiders are not ſo venomous as is ſuppoſed, ſince many perſons ſwallowed them. A perſon is mentioned, who ate all he could find, and who found them to be purgative. He ſpread them on a ſlice of bread, as if they had been excellent marmalade. Moreover, it is maintained, in oppoſition to the popular error, that the ſpider is not able, by its pricking, to kill the toad. It is alſo well known, that chickens, nightingales, and other birds, eat ſpiders without injury; and they have been preſcribed as a remedy chiefly in the tympanis. Liſter, whoſe obſervations on theſe inſects have been numerous, ſays poſitively, that ſeveral ſpiders have a venomous liquor: but the honorable Mr. R. Boyle aſſures us, that he never ſaw any venomous ſpiders in Ireland. Upon the whole, it is obſerved, the different effects of ſpiders are owing partly to a difference in the ſpiders on which experiments have been made, and the different conſtitution of the ſubjects. In ordinary caſes of being bitten or punctured by ſpiders, it will be ſufficient to waſh the wounded part with brine, to apply theriaca, and to preſcribe one or two doſes internally. The freſh leaves of ſage, or thoſe of plantain, have been recommended as topics, and waſhing with vinegar. Recourſe may alſo be had to volatile alkali.

Some think the white matter we often find floating in the air towards the end of ſummer, is produced by ſpiders. See *Air*-Threads.

Spider, *Red*. See Acarus.

The red ſpider is very injurious and deſtructive to different ſorts of plants and fruit-trees, eſpecially in forcing-houſes. It is found particularly ſo to thoſe of the forced French bean, melon, peach, vine, cherry, currant, and ſome other kinds. The generation and production of this inſect are greatly cauſed and promoted by the dry warm heat that is conſtantly kept up in the houſes which contain theſe ſorts of plants and trees, and there are many other circumſtances which combine in bringing it forth. It is an inſect which has no wings, and the female is oviparous.

Several different methods have been attempted in order to the removal and deſtruction of it. Conſtant daily watering, or waſhing the trees, are ſaid to have the power of ſubduing it, but in the execution of the work, care is always to be taken that every part of the leaves be wetted, otherwiſe the inſects ſhelter and ſave themſelves in the dry parts, and are preſerved from the effects of the water.

Moiſture conveyed in ſome way or other is certainly found to be the moſt deſtructive, of any thing yet diſcovered, of theſe pernicious inſects, as well as many others that infeſt hot-houſes. Throwing weak lime-water in a plentiful manner on the under ſides of the leaves, where theſe inſects are commonly found, will, for the moſt part, ſoon deſtroy them.

The following directions have been given for the deſtruction of this ſort of ſpider, when it becomes injurious to melon plants; and the ſame may probably be found uſeful for thoſe of the forced French bean, and ſome other ſimilar kinds.

In caſes of dry weather, and with a dry heat, melon plants are very ſubject to be infeſted with the red ſpider; and the appearances of it may conſtantly be long noticed before the inſects can be ſeen with the naked eye, by the leaves beginning to curl and crack in their middle parts. Whenever they are diſcovered to be in this ſtate or condition, and there is fine warm ſunny weather, the watering of them all over the leaves, both on the under and upper ſides, is adviſed; a watering-pot, with a roſe finely perforated with holes, or a garden-engine, which diſperſes the water in a fine dew-like manner, being employed for the purpoſe. The work ſhould be performed about ſix o'clock in the morning, and the plants be ſhaded with mats about eight, if the ſun ſhine with much power, ſhutting the frames down cloſely until about eleven; and then admitting a ſmall quantity of freſh air, letting the mats remain until about three in the afternoon, when they ſhould be wholly taken away. The ſhade which is thus afforded by the mats prevents the leaves of the plants from being ſcorched or otherwiſe injured by the action of the heat of the ſun while they are in a wet cooled down ſtate. Where a ſoutherly breeze prevails, watering them again about three in the afternoon is recommended, ſhutting them up cloſe as before, to keep the heat in, which cauſes a ſtrong exhalation of the moiſture, and is greatly deſtructive of the ſpiders.

In all theſe waterings, the water is to be thrown as much and as finely as poſſible on the under ſides of the leaves, where the inſects moſtly lodge; the vines or ſtems of the plants being gently turned in that intention, taking great care not to injure them, by which means the water is capable of being eaſily thrown over the whole of the under ſides of the leaves, it being done in a gentle manner, in the modes already ſuggeſted, ſo as not to waſh up the mouldy matters on to the plants: the lights and ſides of the frames which contain the plants, ſhould alſo, at the ſame time, have water plentifully thrown on and againſt them. When theſe waterings are finiſhed, the vines or ſtems of the plants are to be carefully laid down again in their former poſitions. And if the day be ſunny, the mats may be let remain, as already directed, until the leaves of the plants become perfectly dry, air being admitted according to the heat that may be preſent at the time. It is likewiſe further adviſed as a precautionary meaſure, that, before the frames and lights, which are to contain plants of this ſort, are employed, they ſhould be well waſhed, both inſide and out, firſt with clean water, and then with a mixture of ſoap-ſuds and urine; a bruſh or woollen rag being made uſe of in the operation; as by this method the ova or eggs of the ſpiders or other inſects that may have been depoſited and lodged in or on them, in the preceding ſeaſon, may be cleared away and deſtroyed. The exhalations of the water which has been thrown upon the plants, and the frames or boxes that contain them, may alſo be uſeful in killing theſe inſects, in other caſes by keeping them in a cloſe ſtate.

Theſe waſhings ſhould never, however, be performed in cold froſty periods or ſeaſons; and the water made uſe of in ſuch caſes ſhould always be of the rain or ſoft kind.

The mould which has formerly been employed in raiſing theſe plants, where infeſted with the ſpider, ſhould not, on any account, be again had recourſe to for the ſame uſe, as it may contain the ova of theſe inſects. See CUCUMIS.

The waterings, waſhings, and other modes and means of removing and deſtroying this inſect, when it infeſts the fruit-trees and ſhrubs noticed above, are explained under the different proper heads. See AMYGDALUS, PRUNUS, RIBES, and VITIS.

The ſpecies of this genus of inſects are extremely numerous, being more than eighty. This ſort is very common on trees, eſpecially thoſe of the currant kind, being frequently ſeen running on the fruit of it. See ACARUS.

This inſect is injurious and deſtructive to plants and trees, and the production of their fruits, by feeding on their juices; as the ſtems and leaves of them are not unfrequently completely robbed and exhauſted of their moiſture in this way.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, deeply five-cleft, pointed, ſmall, permanent. *Cor.* of one petal, funnel-ſhaped; tube much longer than the calyx, narrowed towards the baſe; limb ſpreading, cloven into five broad, pointed ſegments. *Stam.* Filaments five, ſimple; anthers ſimple. *Piſt.* Germen ſuperior, compoſed of two globes; ſtyle ſolitary, awl-ſhaped, the length of the tube; ſtigma ſimple. *Peric.* Capſule two-lobed, of two cells and four valves. *Seeds* numerous, very minute.

Eſſ. Ch. Corolla funnel-ſhaped. Capſule of two globular cells, with many ſeeds.

1. S. *Anthelmia.* Annual Worm-graſs. Linn. Sp. Pl. 213. (Anthelmenthia quadriphylla; Brown Jam. 156. t. 37. f. 3.)—Stem herbaceous. Upper leaves in fours.—Native of the Weſt Indies and South America. It flowers in July.—*Root* annual, fibrous. *Stem* herbaceous, a foot and half high, channelled, branched. *Leaves* oppoſite, in pairs, thoſe which terminate the branches four together in the form of a croſs, ovate, pointed. *Flowers* in ſhort, herbaceous, cluſtered ſpikes, ranged on one ſide of the footſtalk.

2. S. *marilandica.* Perennial Worm-graſs. Willd. n. 2. "Hope Act. Edin. 1771, v. 3. 151. t. 1." Curt. Mag. t. 80. Woodv. Med. Bot. 288. t. 105.—Stem ſquare. Leaves all oppoſite.—Native of North America, on the edges of woods, in rich moiſt ſituations, flowering in July and Auguſt.—*Root* perennial, fibrous. *Stems* herbaceous, erect, ſix or eight inches high. *Leaves* oppoſite, ſeſſile, entire, ſmooth, ſpreading. *Flowers* large, and extremely handſome, in a terminal ſpike, all on one ſide of the footſtalk, of a bright red or rich ſcarlet on the outſide, yellow or orange-coloured within.

The Engliſh name of this genus, Worm-graſs, is derived from the peculiar efficacy of both the ſpecies as a medicine for perſons afflicted with worms. Dr. Brown, in his Hiſtory of Jamaica, ſays that no other ſimple is equally efficacious with *S. Anthelmia* for this purpoſe, and Mr. Purſh informs us that the roots of *S. marilandica* are in great eſtimation, and ſold under the name of *Pink-root.*

Spigelia, in *Gardening*, compriſes plants of the annual and perennial kind, the cultivated ſpecies of which are, the American worm-graſs (S. anthelmia), and the Maryland worm-graſs (S. marilandica).

Method of Culture.—The firſt ſort, which is annual, and not hardy in its nature, is increaſed by ſowing the ſeeds of it upon a hot-bed, or in ſmall pots plunged into one, in the early ſpring ſeaſon, treating the young plants afterwards in the manner of thoſe of the tender annual ſort.

In the ſecond ſpecies, which is perennial, and ſomewhat hardy, as it does not ripen its ſeeds well in this climate, it muſt be propagated by parting the roots in the autumnal or ſpring months, and putting them in ſeparate pots, or placing them out in warm ſituations.

The latter kind of theſe plants, which have the outſides of their flowers of a bright red colour, and the inſides of a deep orange caſt, produce a fine ornamental effect, as they make an elegant and beautiful appearance during the ſummer months, when placed in collections with others.

Spigelia, in the *Materia Medica*, the root of the ſpigelia marilandica, or worm-graſs root, imparts its bitter taſte to boiling water. It is purgative and anthelmintic; the latter property having been diſcovered by the Cherokee Indians, who call it "Unſtretta," and many opportunities having occurred in this country, as well as America, for evincing its efficacy in worm caſes. In the recent ſtate, and adminiſtered in ſmall doſes, it occaſionally produces giddineſs, dimneſs of ſight, and even convulſions; and theſe effects are aſcribed to its narcotic principle, the action of which its powerful cathartic property prevents, when the doſe is large. It is uſual to adminiſter an emetic previous to the uſe of it; and to aſſiſt its purgative operation by adding two or three grains of calomel, or eight or ten of rhubarb. Its power in expelling lumbrici has been moſt perceptible; and in vinous infuſions of it, it is ſaid to have been beneficial in intermittents. Dr. Barton alſo recommends it in the protracted remitting fever of infants, which often lays the foundation of hydrocephalus. This root may be adminiſtered either in ſubſtance, or in the form of aqueous infuſion. The doſe of the pulverized root may be from grs. x to ʒj, given every night and morning till the worms are expelled. Woodville. Thomſon.

SPIGELIUS, (or Vanden Spieghel,) Adrian, in *Biography*, an eminent phyſician, was born at Bruſſels in 1578. He ſtudied philoſophy and medicine firſt at Louvain, and afterwards at Padua, where he received the degree of M.D. He became thoroughly ſkilled in every branch of his profeſſion, and particularly in anatomy and ſurgery; and after travelling for ſome time to the different ſchools of Germany, he ſettled in Moravia, where he was ſoon appointed phyſician to the ſtates of the province. He had there attained to the higheſt reputation, when he was invited, in 1616, by the ſenate of Venice, to occupy the principal profeſſorſhip of anatomy and ſurgery in the univerſity of Padua, which had become vacant by the death of Caſſerius. He accepted the appointment, and acquitted himſelf with ſo much ſucceſs, that he contributed to render the ſchools of Padua more flouriſhing than they had ever been; and the ſenate recompenſed his ſervices by creating him a knight of St. Mark, and preſenting him with a collar of gold. The apparent vigour of his conſtitution, his vivacity of diſpoſition, and his years, promiſed a continuance of life, and an increaſing reputation; but he was cut off at the age of 47, in April 1625; according to one account, in conſequence of a puncture of his finger by a piece of glaſs, at the marriage-feaſt of his daughter, which was followed by a ſuppurating tumour in the axilla; but according to another, in conſequence of an attack of ſlow fever, brought on by his indefatigable exertions in the performance of his duties. His writings evince that he was a man poſſeſſed of very extenſive medical knowledge. The firſt work which he publiſhed was entitled "Iſagoges in Rem Herbariam Libri duo," printed at Padua in 1606. This work, though not very ſyſtematic, contains ſome intereſting matter. It treats copiouſly on the virtues of plants, reſpecting which he is ſaid to have learned much from the Italian peaſantry, in a tour which he made in the dreſs of a ruſtic. He publiſhed alſo "De Lumbrico lato Liber, cum notis et ejuſdem Lumbrici icone," to which was ſubjoined a letter "De incerto tempore Partûs," 1618. "De Semitertianâ Libri quatuor," Francf. 1624. But the moſt valuable of his writings are thoſe which he compoſed on anatomical ſubjects, and which were publiſhed after his death by his ſon-in-law, Crema. Theſe were entitled "De Humani Corporis Fabricâ Libri X, cum Tabulis 98 ære inciſis," 1625, folio; and "De formato Fœtu Liber ſingularis, æneis figuris ornatus;" to which was annexed "Tractatus de Arthritide," 1626, folio. The firſt of theſe, relating to the ſtructure of the human body, is one of the beſt anatomical works of the time, written with purity, and arranged with great perſpicuity and preciſion, and containing uſeful phyſiological and practical obſervations. There is an edition of this work publiſhed by Bucretius, 1627, who has been cenſured for intermixing his own obſervations with the text of the author. The whole works of Spigelius were collected by Vander Linden, and publiſhed in three volumes folio, at Amſterdam, in 1645. See Eloy Dict. Hiſt. de la Med. Gen. Biog.

SPIGNO, or SPINA, in *Geography*, a town of France, in the department of the Stura, late a marquiſate belonging to Piedmont, on the Belbo; 9 miles S.S.W. of Acqui.

SPIGOLA, in *Ichthyology*, a name given by Paulus Jovius, and ſome others, to that ſpecies of perch which is generally called the *lupus marinus*.

It is a genuine perch, and is diſtinguiſhed from the others by Artedi, by the name of the perch with thirteen rays in the ſecond back fin, and fourteen in the pinna ani.

Authors have called two different fiſh by this name *lupus marinus*, which, conveying no diſtinct idea of the characters of the fiſh, was applicable to one as much as the other: but this name of Artedi admits of no equivocation, and muſt always diſtinguiſh the fiſh.

SPIKE, in *Geography*, an iſland in the harbour of Cork, Ireland, which commands the entrance in ſuch a manner, that it has been regularly fortified at a great expence, and is one of the moſt complete and unaſſailable fortreſſes in his majeſty's dominions. The works, now (1815) nearly completed, have given employment to a great number of men for ſeveral years. Spike iſland is immediately oppoſite to the town of Cove, and about ten miles from Cork.

SPIKE, or *Oil of Spike*, a name given by our druggiſts to an eſſential oil, much uſed by the varniſh-makers and the painters in enamel; and of ſome uſe in medicine.

This oil, when genuine, is brought from Provenoe, and ſome other parts of France, and is there made of lavender. This plant is called in Provence *aſpic*, and thence came the name *oil of aſpic*, which afterwards degenerated into *oil of ſpike*. See LAVANDULA, and OIL.

The manner of making the oil upon the ſpot is this: when the flowers are perfectly ripe, they put them into an alembic with a great quantity of water, and this they diſtil: after ſeveral days' maceration, there ariſes with the water a large quantity of an oil of a fine pale amber colour, and this, ſeparated from the water, is the true and genuine oil of ſpike.

The flower of this plant is the part which yields the largeſt quantity of oil; as is the caſe with all the plants with galeated flowers, of which the huſk, or flower-cup, uſually contains almoſt all the oil of the plant. The aromatic plants, in general, yield indeed but a ſmall quantity of oil, but the vaſt abundance of this plant, in theſe places, makes the expence of gathering it ſo ſmall, that the oil is very cheap. The quantity required on ſeveral occaſions, is, however, much greater than what all the lavender of the country can yield; and the price it is expected to be ſold at is ſo ſmall, that it is not to be wondered that there are ſeveral common adulterations of it.

The moſt uſeful ways of ſophiſticating it, however, are two; the one with the ſpirit of wine, which is eſteemed the leaſt hurtful, and the oil thus ſophiſticated is often called the very beſt of the country. The method Mr. Geoffroy took to diſcover the cheat was this: he procured a long and narrow phial, of an equal diameter all the way up; into this he firſt put an ounce of fair water, and to this he added an ounce of the oil; he marked the height of the water in the phial, then ſhook the two liquors together, and they became milky, and heated on the mixture, which alone would have been a ſufficient proof that there was ſpirit of wine in the oil. After ſome ſtanding the liquor became clear, and the oil floated at the top, but in a much ſmaller quantity than might have been expected, there being not more than a quarter of an ounce of it, the reſt having been ſpirit of wine, which mixed with the water, and thus left all the true oil, which was only one-fourth of the quantity, to float alone on the water, which was greatly increaſed in height in the phial. A pint of this oil of ſpike, therefore, contains only four ounces of the genuine oil, and twelve ounces of plain ſpirit of wine.

The ſecond method of adulterating this oil, which the ſame gentleman had ſuſpected, was eaſily diſcovered next; for on mixing this quarter of an ounce of pure oil of ſpike with three quarters of an ounce of oil of turpentine, there was produced an ounce of liquor, which appeared wholly the ſame with the oil of ſpike commonly ſold in the druggiſts' ſhops. And indeed, much of what is uſually ſold is worſe than this, being no other than oil of turpentine ſcented with a ſmall quantity of true oil of ſpike.

The ready way of diſcovering the oil counterfeited with oil of turpentine, is to wet a paper in it, and ſet it on fire; the turpentine will here be diſcovered by the thick ſmoke it yields, it being, of all vegetable oils, that which yields much the thickeſt cloud in burning: and, on the contrary, that which has been adulterated with ſpirit of wine, will be diſtinguiſhed by the ſame trial, by its yielding a much finer and thinner ſmoke, and burning with a bright blue flame. If they be tried by firing them in a ſpoon, that which is adulterated with ſpirit of wine will burn very bright, and yield no fume at firſt; but as it grows near the bottom it will ſmoke a little, and finally will leave no reſiduum, except that it varniſhes over the inſide of the ſpoon: that adulterated with the oil of turpentine will burn more vehemently, ſmoke more, and leave a coarſer varniſh upon the ſpoon; and if it be of the coarſeſt kind, that is, if it hath been adulterated with badly rectified oil of turpentine, the fume will be the more abundant, and there will be left in the ſpoon a fetid matter, reſembling melted pitch.

Mr. Geoffroy tried whether, in the buſineſs of varniſhing, the oil of turpentine alone might not do as well as the oil of ſpike; he found that it dried perfectly well, but that it left a ſtinking ſmell upon the work, which never went off; whereas the mixture of this oil with that of ſpike, makes a ſmell like neither, and which ſoon goes off.

An ounce of oil of turpentine, with only twenty drops, either of our common oil of lavender, or the pure oil of ſpike, makes a liquor tolerably well ſcented, and which ſerves for the purpoſes of oil of ſpike. If two drachms of our oil of lavender be added to ſix drachms of ſpirit of wine, they immediately mix; and this, afterwards mixed in a ſmall proportion with oil of turpentine, makes a ſort of oil of ſpike.

The moſt regular method, however, that the artificer can uſe, if he can get the genuine oil of ſpike, is to mix one ounce of it with three ounces of oil of turpentine, which perfectly fits it for this purpoſe, and makes it the ſame with that in common uſe. The method of making this perfectly pure, is to rediſtil it in a balneum Mariæ; there will thus be procured an oil highly rectified, and pellucid as water, which will dry away as ſoon as touched on any thing. The great diſadvantage attending the oil of ſpike adulterated with ſpirit of wine is, that it will not readily mix with all the ſorts of varniſh.

Having gone through the properties of oil of ſpike, in regard to varniſh, it remains to inquire into them in regard to its other great uſe in enamel, and to conſider the effects of the two uſual methods of adulterating it in this work.

The oil of ſpike which wants body, is not at all fit for enamelling, becauſe it dries too ſuddenly, and does not at all aſſiſt the natural dryneſs of the enamel, which is only a ſort of powder of glaſs; and the particles of this powder, with a fluid of too little body, are not manageable by the artiſts, ſo that the colour never is brought to a due conſiſtence; and when the oil has too much body, the mixture becomes too tenacious, and is as unmanageable in that extreme as in the other; and this fault is attended with another very great miſchief, which is, that the fume raiſed by this oil, when heated, is often ſo groſs, as to deſtroy the beauty of the colours. In ſhort, thick oil of turpentine is always deſtructive of enamels by its ſmoke.

The true compoſition for enamelling is oil of ſpike mixed with ſpirit of wine, but the proportions muſt be nicely regulated from repeated trials: for if the quantity of the ſpirit be too large, it is apt to ſeparate itſelf from the oil and colour in the drying, and this always ſpoils the gloſs and beauty of the work. Artificers obſerve, that oil of ſpike does beſt for their purpoſes, after it has been kept two or three years. But this is only owing to the oil's being adulterated with ſpirit of wine, and uſually containing too large a proportion of the ſpirit when firſt ſent over: it becomes better for uſe when a part of that ſpirit has had time to evaporate in the keeping. It would be a better way for theſe curious works, to procure the oil pure, and then occaſionally mix it with ſuch a proportion of ſpirit of wine, as experience ſhews to be the moſt proper. Mem. Acad. Par. 1716.

Spike *a Gun,* in *Military Language, &c.,* ſignifies to choak up the touch-hole of a piece of ordnance, ſo as to render it uſeleſs. See Nail.

Spike-*Roller,* in *Agriculture,* a very uſeful implement of the roller kind, firſt introduced by Mr. Randall of York to the notice of the farmer. It has been found of much advantage in bringing ſtiff cloddy lands into a ſtate of ſuitable pulverization and fineneſs of mould for being ſown. It is likewiſe employed, in a beneficial manner, on ſward-land that is worn out and moſſy; by preparing it for the application of earthy compoſts and graſs-ſeeds. But it is remarked by the inventor, that in this buſineſs the roller muſt go up and down, till the ſwarth and ground are perfectly well broken up: this being done, the ſeeds of clover, trefoil, and rye-graſs, or any other mixed with them, muſt be ſown in the uſual way and quantity; then the compoſt muſt be ſpread over the ſeeds, ſo as to cover them; and a common barley-roller, with a thorn-buſh faſtened to it, muſt follow, and the ground be ſhut up, leſt the cattle ſhould do harm by treading.

In reſpect to this ſort of roller, the dimenſions in length were ſeven feet, the diameters at the ends eighteen inches, and the whole cylinder made of the heart of oak; and when the irons were burnt in, and the man ſeated on the box deſigned for that purpoſe, the weight of the whole was about a ton. But the blunt ends of the irons were oppoſed to the clods, and run more taper, till they came to the ſurface of the cylinder, into which the irons were burnt, and inſerted about three inches, which was their length above the ſurface of the roller, and which he always found very ſufficient to cruſh the hardeſt clod that ever came in their way. Had he, indeed, attempted to go on the ground, when the ſoil was not perfectly dry, this poſition of the irons would have carried the clods round with the roller; for it is not its province to ſqueeze, but cruſh. Nor indeed can a man do more harm to his ground than going upon it, when it is not quite dry, with a roller conſtructed in this way. He had the irons fixed in four inches aſunder, in the firſt row, from end to end. The ſecond row began juſt between the firſt and ſecond irons of the firſt row. The third row was like the firſt; and the fourth like the ſecond. Then alternately for the whole ſurface of the cylinder, as near as poſſible, the irons were four inches aſunder in each individual row; and four inches from row to row, as nearly as the ſuperficies of the cylinder would permit. He does not know how to convey a juſter idea of the ſhape of the irons than to call them ox-harrow teeth, or thoſe of a very large harrow; for when he ſent for the workman, he deſired him to make ſo many of this denomination, ſix inches in length, and burn the ſmall end three inches into the wood. This is a roller that requires a ſtrong team in performing its work.

But in addition to theſe uſes, it has been ſuggeſted that it may likewiſe be very uſeful in preparing clay for the making of canals, or pieces of water: for where, as ſometimes happens, the clay grows dry, and will not admit of being duly tempered for uſe, without great pains in breaking it, a very large quantity may very ſoon be reduced to the requiſite fineneſs, by ſpreading it on hard ground in a due thickneſs, and paſſing this roller a few times over it. In extenſive works, much trouble and labour may ſometimes be ſaved by this means, where ſuch a roller is at hand, and the clay prepared in a manner that will anſwer the purpoſe much more effectually.

It may alſo be noticed, that this is a ſort of tool which no farm, where the land is a ſtiff clay, or in the leaſt liable to clot, ſhould want: for beſides the conſtant advantage of ſaving labour, and bringing land to a better condition for any kind of ſowing than the plough and harrow, with any aſſiſtance of the work of hands, can make it; in favourable ſeaſons, and under certain circumſtances, the loſs of the whole crop, by an otherwiſe unavoidable delay beyond the ſeed-time, may be with certainty prevented.

It has been ſtated as an improvement in this implement, in order to prevent its tearing up the ground, and the great ſtreſs that is upon the frame in turning, to have it divided into two parts. Let the ends of each part be bound with narrow, but ſtrong, bands of iron, and let the ſpikes at the ends be placed cloſe to them; let each part have a ſeparate frame; but let the cheeks, in which the inward gudgeons turn, be made of iron plates, about two inches wide above, and four where the gudgeons enter; the thickneſs, a common flat bar of iron: and theſe fixed in any firm manner to two cheeks of wood, reaching down juſt to the bands, and of ſuch a thickneſs at bottom as not to interrupt the ſpikes. Let the inward gudgeons be made with quite flat heads, to prevent their ſlipping out in working, and bring the two ends of the roller nearer together, which is of conſequence, as the fewer clots will be miſſed in working.

Let the frames be joined together by four eyes, like thoſe of a ſmall gate, two at one end, about five or ſix inches apart; the two at the end of the other, to take place juſt within them; an iron pin being put through all four, and keyed. Let the thills be placed juſt on the middle of each frame, and a bar of wood juſt behind the horſe to ſtrengthen them; the bar ſawed through in the middle, and joined by a ſtrong flat hinge; one ſide made to haſp upon a ſtaple, kept down with a wooden clet. This gives the whole proper play in working.

The ſpikes are about four inches without, and three within the wood: the thickneſs of the roller and number of ſpikes may be determined, in ſome meaſure, by the nature of the ſoil it is to work upon. Thus formed, it will be found, it is ſaid, next to the plough, the moſt uſeful inſtrument in tillage, not only in reducing a ſtiff ſoil, but, with a buſh at its tail, to cover the ſeed, when ſown, much more effectually, and in a better manner, than a harrow, as it turns up the earth light and fine behind it; and, though ſeemingly unwieldy, will turn with eaſe, and may be worked with one, two, or three horſes at moſt, upon any land that is of a proper dryneſs to work upon.

This implement may likewiſe be employed to aſſiſt in reducing the half-burnt turf of burn-baked land, which requires much labour, as commonly done by hand; but by going over the land ſeveral times with the ſpike-roller, and harrowing it with heavy harrows alternately, to pull up the turfs, or ploughing them up, they may be reduced fine in a much ſhorter time, and at a much leſs expence, than by beating or breaking them by hand. The mode of conſtructing the tool, in the common manner, has been already ſhewn. See ROLLER.

Still more lately, a clod or improved roller of this kind has been conſtructed by Mr. Blithe Harries of Benthall-houſe, near Shiffnall, in which the danger of the horſes being injured in turning, by the ſpikes, is obviated. It is found very effectual on ſtrong ſoils, and well adapted for breaking and reducing clods, pulverizing old turf fallows, and preparing land previous to ſowing barley, and many other purpoſes. He deſcribes it in the Agricultural Magazine as conſiſting of twenty-one caſt-iron wheels, twenty-one inches and a half in diameter, the edges three inches aſunder; or a ſmaller pattern, conſiſting of fourteen wheels, twenty-three inches in diameter, the edges four inches and a half aſunder, faſtened upon an iron axle-tree, with a large wheel at each end to carry it to the field. It is further ſtated, that the invention is Mr. Gittin's, of the Iſle, Shropſhire, an ingenious farmer, who had one made at Mr. Onion's foundery, Broſeley; and Mr. Harris now makes them at his iron works, the price of which, in either of the patterns, is 10*l.*, excluſive of the row of ſpikes to clear dirt or ſtones, and the ſhafts.

In this ſtate it forms a ſort of cutting or bruiſing implement of the kind, and may be of very great utility in different caſes of ſtiff, cloddy, arable land, as well as in thoſe of the tough, unproductive, overrun ſward kind. It is capable of performing a good deal of work, in both theſe caſes, in a ſhort ſpace of time, and in the moſt effectual manner.

All implements of theſe kinds having great power and diſpatch, are conſequently capable of very general application in the buſineſs of tillage, as well as graſs huſbandry. They may be conſtructed in different cheap methods, and be made uſe of with much advantage in a variety of ſituations, where they are at preſent perhaps wholly, or in a great meaſure, unknown.

This implement is ſometimes called ſpiky-roller.

SPIKELET, in *Botany*, *Spicula*, is technically uſed for the aſſemblage of the florets of graſſes, within the calyx; and which conſiſts of two florets only in *Aira* and *Holcus*; of many in *Poa*, *Bromus*, &c.

SPIKENARD, *Baſtard French*. See NARDUS.

SPIKENARD, *Celtic*, a ſpecies of *Valerian*; which ſee.

SPIKENARD, *Falſe*. See LAVANDULA.

SPIKENARD, *Ploughman's*. See BACCHARIS.

SPIKENARD, *Ploughman's*, is alſo the name of a ſpecies of flea-bane, or *conyza*; which ſee.

SPIKENARD, *Nardus*, or *Spica Nardi*, in the *Materia Medica*, a kind of vegetable ſhoot growing even with the ground, and ſometimes, in part, within the ground, belonging to an Indian graſſy-leaved plant, of which we have no particular deſcription. The nard, as it is brought to us, is a congeries of ſmall, tough, reddiſh-brown fibres, forming a bunch, or ſpike, about the ſize of a finger.

The ſpica nardi is uſually reckoned in the number of roots. It is alſo called *nardus Indica*; becauſe brought from the Eaſt Indies.

It is now kept in the ſhops chiefly as an ingredient in the mithridate and theriaca, but was formerly employed in the ſame intention as the Celtic, and is ſaid to be uſed among the Orientals as a ſpice. It is moderately warm and pungent, accompanied with a flavour not diſagreeable. Lewis.

There is alſo another kind, called *ſpica Celtica*, a ſpecies of valerian, growing in the Alps, from whence the ſhops have been generally ſupplied with the dried roots, conſiſting of a number of blackiſh fibres. This root has been recommended as a ſtomachic, carminative, and diuretic: at preſent it is ſcarcely otherwiſe made uſe of, in this country, than as an ingredient in mithridate and theriaca, though its ſenſible qualities promiſe ſome conſiderable medicinal powers. It has a moderately ſtrong ſmell, of which it is very retentive, and a warm, bitteriſh, ſubacrid taſte, reſembling thoſe of common wild valerian. Lewis.

SPIKENARD, *Ointment of*. See NARDINUM *Unguentum*.

SPIKES, or, as the ſeamen call them, *ſpeeks*, in a *Ship*, are large long iron nails with flat heads. They are of divers lengths, ſome a foot or two long, and ſome are jagged, ſo that they cannot be drawn out again. They are uſed to faſten the planks and timber. See MARLING-*Spike*.

SPIKING *up the Ordnance*, a ſea-phraſe, uſed for faſtening a quoin with ſpikes to the deck, cloſe to the breech of the carriages of great guns, that they may keep cloſe and firm to the ſhip's ſides, and not get looſe when the ſhip rolls, and by that means endanger the breaking out of the butt-head of a plank. See QUOIN.

SPILAMBERTO, in *Geography*, a town of Italy, in the department of the Panaro; 8 miles S.E. of Modena.

SPILANTHUS, in *Botany*, originally called SPILANTHES by Jacquin, is derived from σπιλος, *a ſpot*, and ανθος, *a flower*, becauſe of its dotted or ſpeckled flowers.—Jacq. Amer. 214. Schreb. 543. Willd. Sp. Pl. v. 3. 1712. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 493. Juſſ. 187. Lamarck Dict. v. 7. 345. Illuſtr. t. 668. Gærtn. t. 167.—Claſs and order, *Syngeneſia Polygamia Æqualis*. Nat. Ord. *Compoſitæ Oppoſitifoliæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common calyx* nearly hemiſpherical, imbricated, with lanceolate, linear, compact ſcales, in a double row. *Cor.* compound, uniform, tubular, conically convex, the florets numerous, equal, all perfect, funnel-ſhaped, with a four or five-cleft, reflexed limb. *Stam.* Filaments four or five, capillary, very ſhort; anthers cylindrical, tubular. *Piſt.* Germen oblong, compreſſed; ſtyle thread-ſhaped, the length of the ſtamens; ſtigmas two, recurved. *Peric.* none, except the unchanged calyx. *Seeds* ſolitary, oblong; compreſſed, flattiſh. *Down* with a membranous margin, and two unequally-ſized awns at the tip. *Recept.* briſtly, conical, its ſcales compreſſed, deciduous.

Obſ. In *S. atriplicifolius* the ſeeds have no awns; and in *S. Acmella* and *uliginoſa* the radius is very ſmall, and compoſed of only three or five flowers.

Eſſ. Ch. Receptacle chaffy, conical. Down with two awns, one larger than the other. Calyx nearly equal.

1. S. *urens*. Biting Spilanthus. Willd. n. 1. Jacq. Amer. t. 126. f. 1.—Leaves lanceolate, entire. Stem proſtrate.—Native of ſandy fields in America, about Carthagena, flowering from May to October. *Root* perennial, fibrous. *Stems* herbaceous, round, ſmooth, procumbent, branched, fibrous at the joints. *Leaves* oppoſite, ſeſſile, ſmooth, ribbed. *Flowers* ſolitary, capitate, terminal, ſcentleſs, white, dotted with black.

The leaves of this ſpecies poſſeſs a hot, pungent flavour, reſembling the root of *Pyrethrum*, or Pellitory of Spain, for which they are occaſionally ſubſtituted.

2. S. *Pſeudo-Acmella*. Baſtard Acmella or Spear-leaved Spilanthus. Willd. n. 2. (Verbeſina Pſeudo-Acmella; Linn. Sp. Pl. 1270. Chryſanthemum mederaſpatanum latifolium, ſcabioſæ capitulis parvis; Pluk. Alm. 99. t. 159. f. 4.)—Leaves lanceolate, ſerrated. Stem erect.—Native of Ceylon, flowering in July. *Root* annual. *Stem* two feet high, round, branched, rather hairy. *Leaves* oppoſite, ſtalked, ovate, veined, the ſtalks channelled and ſlightly downy. *Flowers* ſolitary, yellow, on long, upright, naked ſtalks.

3. S. *Acmella*. Balm-leaved Spilanthus. Willd. n. 3. (Verbeſina Acmella; Linn. Sp. Pl. 1271. Abcdaria; Rumph. Amboin. v. 6. 145. t. 65.)—Leaves ovate, ſerrated. Stem erect. Flowers radiated.—Native of Ceylon, flowering from July to the end of ſummer. *Stems* about two feet high, much branched. *Leaves* like thoſe of the laſt ſpecies. *Flowers* ſolitary, radiated, yellow, on very long ſtalks. This plant is reputed to be a ſpecific for the ſtone in the Eaſt Indies. It differs chiefly from *Pſeudo-Acmella*, in being more branched, and in having radiated flowers.

4. S. *uliginoſa*. Boggy Spilanthus. Willd. n. 4. Swartz Prodr. 110. Ind. Occ. 1291.—Leaves ovato-lanceolate, notched. Stem erect, forked. Flowers radiated, terminal, ſtalked.—Native of the ſouth of Jamaica, in clayey, ſwampy ground, flowering in the ſpring. *Root* annual, long, ſimple, thread-ſhaped. *Stem* herbaceous, half a foot high, round, ſmooth, reddiſh. *Leaves* oppoſite, ſtalked, ſmooth. *Flowers* roundiſh at firſt, afterwards conical, yellow.

5. S. *exaſperata*. Rough or Warty Spilanthus. Willd. n. 5. Jacq. Ic. Rar. v. 3. t. 584. (S. radicans; Jacq. Collect. v. 3. 229.)—Leaves ovate, wavy. Stem forked, aſcending, rough with warts at the baſe. Calyx of five leaves.—Native of Venezuela, and flowering in ſtoves from July to January. *Root* branched, whitiſh. *Stem* nearly three feet in height, erect, ſomewhat hairy, rough towards the baſe, with ſharp, fleſhy warts. *Leaves* oppoſite, ſtalked, acute, ſlightly ſerrated, roughiſh. *Flowers* ſolitary, white, on downy ſtalks. *Seeds* black, fringed with white hairs.

6. S. *alba*. White-flowered Spilanthus. Willd. n. 6. L'Herit. Stirp. Nov. t. 4.—Leaves ovate, wavy; lower ones alternate. Stem branched, aſcending. Calyx of many leaves.—Native of Peru. It flowers in June and July. *Root* annual, fibrous, pungent, exciting ſaliva, whence Murray called this ſpecies *ſalivaria*. *Stem* herbaceous, wavy, upright, rugged, panicled. *Leaves* ſtalked, ſpreading, bluntiſh, hairy, fringed. *Flowers* terminal, ſolitary, conical, obtuſe, white.

7. S. *atriplicifolia*. Orache-leaved Spilanthus. Willd. n. 7. (Bidens atriplicifolius; Linn. Sp. Pl. 1168.)—Leaves alternate, deltoid, toothed, ſtalked, furniſhed with ſtipulas. Stem panicled.—Native of South America. *Stem* herbaceous, ſmooth. *Leaves* alternate, on ſlender ſtalks. *Stipulas* equal, kidney-ſhaped, like little ears. *Flowers* ſolitary, terminal. *Seeds* without awns, oblong.

8. S. *inſipida*. Taſteleſs or Mild Spilanthus. Willd. n. 8. Jacq. Amer. 215. t. 126. f. 2.—Leaves obovate, toothed, ſeſſile.—Native of America, and found by Jacquin at the Havanna, where it flowers in the winter. *Stems* ſhrubby, round, branched, procumbent. *Leaves* oppoſite, nearly ſeſſile, ſmooth, attenuated at the baſe. *Flowers* like thoſe of *urens*, and like that ſpecies the leaves of this have a ſalt or biting flavour, but in a milder degree, ſo that the ſpecific name is not extremely appropriate.

9. S. *oleracea*. Eſculent Spilanthus. Willd. n. 9. Jacq. Hort. Vind. v. 2. 63. t. 135.—Leaves ovate, heart-ſhaped, ſerrated. Stem branched, diffuſe.—Native of the Eaſt Indies, flowering at Kew from July to November. *Stems* a foot long, proſtrate, round, ſomewhat rugged. *Leaves* oppoſite, dark green above, yellowiſh or glaucous beneath. *Flowers* ſolitary, terminal, forming a ſort of cylinder, yellow. *Seeds* brown, fringed with white hairs.

10. S. *tinctoria*. Dyers' Spilanthus. Mart. Mill. Dict. n. 5. Loureir. Cochinch. 484.—Leaves lanceolate, ſerrated, ſmooth. Stem diffuſe. Flowers numerous, terminal.—Found on cultivated ground, in China and Cochinchina. *Stem* herbaceous, three feet high, rather procumbent, round. *Leaves* oppoſite, ſmooth, rather ſucculent, bright green. *Flowers* of a blueiſh-white hue. The leaves when bruiſed yield a fine blue colour, whence it is cultivated by the natives for dyeing. This is very cloſely allied to *S. Acmella*.

SPILBACH, in *Geography*, a town of Bavaria, in the territory of Rothenburg; 4 miles W.N.W. of Rothenburg.

SPILE, in *Ship-Building*, a plug made of fir to fill up holes, where nails have been driven, to prevent leaking, &c.

Spile, in *Rural Economy*, a piece of wood ſharpened at the point, and drove down into the ground, on the ſides of rivers, or other places, for the purpoſe of protecting their banks, or other parts, againſt the deſtructive violence of the waters. They ſhould be well proportioned for the purpoſe, and be very firmly driven down by proper machinery.

But in whatever way, or however firmly, ſpiles may be driven down into the ground, they never form a good or ſecure defence againſt the force of river-currents. The only method of completely effecting this is now well underſtood to be that of making the banks to ſhelve, or ſlope well backward from the rivers, and throwing the force of ſuch ſtreams in new, contrary, or other directions than thoſe to which they have been accuſtomed. In theſe ways much is not unfrequently accompliſhed, without any great deal of labour, trouble, or expence in any manner.

Spile is alſo a term provincially uſed to ſignify the vent-peg of a caſk.

SPILEMBERGO, in *Geography*, a town of Italy, in Friuli, on the Tajamento; 14 miles W. of Udina.

SPILINGS, in *Ship-Building*, the dimenſions taken from a rule-ſtaff, a mould's edge, or ſtraight line, to trim or fay one piece to another.

SPILKEVY, in *Geography*, a town of Norway, in the province of Drontheim; 88 miles S.W. of Romſdal.

SPILL, *To*, in *Sea-Language*, is to diſcharge the wind out of the cavity or belly of a ſail, when it is drawn up in the brails, in order to furl or reef it. This is performed either by collecting the ſail together, or by bracing its edge to the wind, ſo as to ſhiver or be laid aback. Falconer.

SPILLING-Lines, in a *Ship*, certain ropes fixed occaſionally to the main-ſail, and fore-ſail, in tempeſtuous weather, for raiſing or furling them more conveniently. They are paſſed through blocks above the yard, and thence leading down before the ſail, come under its bottom, and return upwards behind it to the yard, where they are faſtened; ſo that the ſail by this effort is cloſely and immoveably confined to the yard. Falconer.

SPILOMA, in *Botany*, ſo called by Acharius, from σπιλωμα, *a ſtain*, or *ſpot*, in alluſion to the appearance of the fructification.—Ach. Meth. 9. Lichenogr. 23. t. 1. f. 1. Syn. 1. Sm. Engl. Bot. v. 29. 2075.—Claſs and order, *Cryptogamia Algæ*. Nat. Ord. *Algæ*, *Lichenes*.

Eſſ. Ch. Receptacles ſhapeleſs, without a border, hairy and powdery, in an uninterrupted cruſt.

This minute and obſcure genus of the Lichen tribe has long been overlooked, or confounded with other things. The ſpecies, which are ſixteen in Acharius's recently publiſhed *Synopſis*, are found either on old wood, the bark of trees, or on rocks and walls. Thirteen are figured and deſcribed in Engl. Bot. v. 29—36. Some of theſe, as *S. Vitiligo*, t. 2075, looks to the naked eye like a little grey duſt, ſcattered over the pales on which it grows, and ſtaining the finger when touched. Others reſemble cruſtaceous Lichens, particularly *Lecideæ*; but are diſtinguiſhed by their black powder, which comes off with a touch; as *S. verſicolor*, t. 2076, and *varioloſum*, t. 2077, both found on old trees. *S. auratum*, t. 2078, is ſtill more remarkable for the internal orange-colour of its receptacles, which becomes viſible whenever they are rubbed or broken.

SPILSBY, in *Geography*, a market-town in the eaſt diviſion of the ſoke of Bolingbroke, parts of Lindſey, in the county of Lincoln, England, is ſituated on an eminence, overlooking to the ſouth a large tract of marſh and fen land, which is bounded by Boſton Deeps and the German ocean. Spilſby is the chief town in the ſouthern part of Lindſey diviſion, and is 31 miles E. from Lincoln, and 134 miles N. from London. It conſiſts principally of four ſtreets, uniting at the market-place, which forms a ſpacious ſquare, interſected in the centre by a row of houſes, with the market-croſs at the eaſt end, and the town-hall at the weſt. The market-croſs conſiſts of a plain octagonal ſhaft, with a quadrangular baſe; the whole elevated on five ſteps. The town-hall, a plain brick building, ſtanding on arches, was built in 1764, on the ſcite of the old hall, which, being in a ruinous ſtate, had been taken down. The general quarter-ſeſſions of the peace, for the ſouthern diviſion of the parts of Lindſey, have been holden here for upwards of an hundred years. The pariſh-church, ſituated on the weſt ſide of the town, is an irregular building, conſiſting of north and ſouth aiſles, the latter of much larger extent than the reſt of the edifice. A chapel occupies the extremity of the body of the church, in which are ſome ancient monuments, belonging to the families of Beke, Willoughby, and Bertie. At the weſt end of the church is an embattled tower, of a more modern date than the other parts of the ſtructure, and probably erected about the time of Henry VII. Here is a ſmall free-ſchool, ſupported by the rents of certain tenements bequeathed for that purpoſe; and a Sunday ſchool, recently eſtabliſhed, promiſes to be of great advantage to the lower claſſes of the people. A weekly market is held on Mondays, and three fairs annually. The population return of the year 1811 ſtates the number of houſes to be 230, occupied by 963 perſons.

At Ereſby, two miles from Spilſby, was formerly a manſion, noticed by Leland, belonging to the Bekes and to the Willoughbys. It was taken down, and another built on the ſcite, which was deſtroyed by fire: a ſtately avenue of trees leads to the ſcite. The place is now abandoned for the more ſplendid domain of Grimſthorpe. Ereſby was a grant from William the Conqueror to Walter Beke. It was poſſeſſed ſucceſſively by the Bekes, Willoughbys, and Berties, till the year 1778, when, with the manor of Spilſby, it became the property of ſir Peter Burrell, now lord Gwydir, by his marriage with lady Willoughby, daughter and coheireſs of the duke of Ancaſter. Beauties of England and Wales, vol. ix. Lincolnſhire, by J. Britton, F.S.A.

SPIN Hay, *To*, in *Military Language*, is to twiſt it up in very hard ropes, for an expedition: ſo that it may be the leſs bulky for the cavalry to carry behind them.

SPINA, in *Botany* and *Vegetable Phyſiology*, a thorn originating from the ſubſtance of the wood itſelf. (See Fulcra.) Linnæus remarks that a thorn is liable to diſappear by culture, or richneſs of ſoil, as in the pear-tree. Hence he ſpeaks of ſuch plants as becoming tame by the influence of good treatment; whereas prickles, *aculei*, ſeated in the bark, are not affected by ſimilar cauſes. The reaſon is well explained by Willdenow, who juſtly conſiders thorns as of the nature of abortive branches, ſtunted in their growth for want of nouriſhment.

Spina, in *Geography*, a town of France, in the department of the Tanaro; 9 miles S.W. of Acqui.

Spina *Bifida*, *Cloven ſpine*, in *Surgery*, frequently named alſo *Hydrorachitis*, is a tumour for the moſt part ſituated on the ſpines of young children, commonly on the lumbar vertebræ; occaſionally on the dorſal or cervical ones; and ſometimes, though leſs frequently, on the os ſacrum.

A tumour of a ſimilar nature is now and then obſerved upon the head. Richter's Chirurg. Bibliothek, 9 band, p. 186.

In caſes of ſpina bifida, the ſwelling is ſoft, and may be gradually diminiſhed, or even made to diſappear entirely by preſſure; but it always returns again immediately when the preſſure is removed. The fluctuation of a fluid is diſtinctly perceptible to the touch. The integuments retain their natural colour and appearance. However, the children ſeem to experience pain when the tumour is compreſſed, or when they are placed upon their backs. The ſize of the ſwelling is extremely various, it does not often exceed that of an orange; but, in a few inſtances, it is much more conſiderable.

The generality of children affected with ſpina bifida are deficient in ſtrength and vigour, and are ſubject to frequent diarrhœa. Some cannot retain their urine and feces. A weakneſs and emaciation are often particularly obſervable in the lower extremities, which, indeed, are ſometimes almoſt paralytic. Though moſt children agree with this account, it deſerves notice, that many others are, in every reſpect except the tumour, perfectly healthy and well formed.

When a ſpina bifida is diſſected, the ſwelling is found to conſiſt of a ſac, filled with an aqueous fluid, and compoſed of the integuments, and of the membranous ſheath which lines the canal of the ſpinal marrow. The lining of the ſpinal canal protrudes through a fiſſure in the vertebræ. This fiſſure is owing to an imperfect formation of theſe bones, and is commonly found at their poſterior part, where the ſpinous proceſſes would otherwiſe be. The preternatural opening is ſometimes confined to one bone, and then the ſwelling frequently has a ſmall baſe. In many inſtances, the oſſification of ſeveral of the vertebræ is not completed behind, ſo that the canal for the ſpinal marrow reſembles an open furrow. Even the whole ſpine, from one end to the other, has been found thus imperfect. (Maret, Mem. de Dijon, vol. ii. p. 105.) The aperture has been known to extend through the body of the affected vertebra, ſo that the finger could be paſſed quite through into the abdomen. (Saltzmann, De Tumoribus quibuſdam Seroſis externis.) In one example, there was not only a furrow in the vertebræ, all the proceſſes of theſe bones were wanting. Richter's Chir. Bibliothek, 4 b. 2 ſt. p. 350.

In general, the ſac is filled with a clear, tranſparent fluid; but occaſionally, the contents are turbid, yellowiſh, and bloody. The portion of the ſpinal marrow ſurrounded by the fluid is generally ſoftened, and almoſt like mucus, or thin matter. Mem. de l'Acad. de Dijon, vol. ii.; and Richter's Anfangſgr. der Wundarzneykunſt, band 2. p. 236, Dritte Auflage.

Children afflicted with this diſeaſe ſometimes ſuffer at the ſame time from hydrocephalus. They ſeldom live longer than a year after birth. The tumour generally continues to enlarge. Occaſionally it inflames and ulcerates, and then death very ſoon follows. Children are obſerved to live longeſt when the ſwelling is remote from the head. The inſtances of perſons attaining a middle age with this diſorder are rare, and theſe ſubjects have moſtly had their lower extremities in a paralytic uſeleſs ſtate. Examples, however, are recorded, in which patients labouring under this affliction, have lived to the ages of eight, ſeventeen, twenty, and fifty. Acrell K. Vetenſkaps, Ac. Haedligar, 1748, p. 91. Warner's Caſes in Surgery, p. 136, ed. 4. Hochſtaetter, Diſſ. de Spina Bifida, Altorf, 1703.

Experience has proved, that puncturing the tumour with a lancet, and thus diſcharging the fluid, either at once or gradually, cannot be practiſed without inducing fatal conſequences. Alſo, when the ſwelling ulcerates and burſts of itſelf, the child periſhes; nor has tying the pedicles of ſuch ſpinæ bifidæ as have narrow baſes proved more ſucceſsful. Some years ago, Mr. Abernethy ſuggeſted the method of letting out the fluid, healing the puncture directly afterwards, and repeating the ſame proceedings as often as neceſſary. (See Abernethy's Surgical and Phyſiological Eſſays, parts i. and iii.) This gentleman tried the plan in one inſtance, and though it was not attended with ultimate ſucceſs, it did not ſeem to bring on the ſudden fatal ſymptoms, which are the uſual effects of letting out the fluid in the common way.

This laſt propoſal, which originated with Mr. Abernethy, is important, inaſmuch as recent obſervations have proved, that a practice founded on the foregoing principles may actually effect a cure of a diſeaſe that, until very lately, always baffled the art of ſurgery. It is to Mr. A. Cooper that we are indebted for the mode of puncturing ſpinæ bifidæ with a fine needle, thus letting out the fluid from time to time, and promoting a cloſure of the opening in the ſpine, by applying a compreſs and bandage. The adheſive inflammation, in fact, obliterates the cavity in which the fluid collects, and the diſeaſe ultimately does not return. In one caſe, Mr. A. Cooper ſeems to have accompliſhed in this manner a perfect cure. See Medico-Chirurgical Tranſ. vol. ii. caſe 2, p. 326.

This eminent ſurgeon, however, purſues two modes of treatment for the relief of children afflicted with ſpina bifida; one palliative, the other radical.

The firſt conſiſts in treating the caſe as a hernia, and applying a truſs to prevent its deſcent; the ſecond, in pricking the tumour with a fine needle, and in producing an adheſion of the ſides of the ſac, ſo as to cloſe the opening in the ſpine, and ſtop the diſeaſe altogether. The firſt is attended with no riſk; the ſecond expoſes the patient to much conſtitutional irritation; but, if ſucceſsful, hinders the future recurrence of the diſeaſe. Even when the adheſive proceſs cannot be effectually accompliſhed by the ſecond plan, the palliative method may yet be tried. See caſe 4, lib. ſupra cit.

Unfortunately, there are numerous caſes of ſpinæ bifidæ which leave no hope of cure. The following examples of this deſcription are pointed out by Mr. A. Cooper.

If the tumour is connected with an unnatural enlargement of the head, hydrocephalus internus is conjoined with ſpina bifida, and the water will accumulate in the ventricles of the brain, whether the radical or palliative treatment of the tumour on the back be tried.

If the lower extremities are paralytic, or the feces and urine are diſcharged involuntarily, there is no hope of relief.

If the tumour has burſt at the time of birth, or ſoon afterwards, little expectation of a cure can be indulged; for although the opening in the ſkin may be cloſed with lint and adheſive plaſter, and union be produced, ſo that no more of the fluid can eſcape, yet hydrocephalus internus will follow.

The deficiency of the ſpine is ſometimes ſo great, that the tumour, at the time of the child's birth, is very conſiderable; the nerves are protruded out of the ſpinal canal; the ſpinal marrow is injured; and all attempts at a cure muſt be unavailing. Medico-Chirurgical Tranſ. vol. ii.

In this diſeaſe, purgatives and diuretics have been tried in vain; and no outward applications, excepting preſſure, have been found to do the leaſt good. Richter has ſuggeſted making two iſſues near the tumour; but the propoſal hardly brings with it a promiſe of utility. In ſhort, in the preſent ſtate of our knowledge, the practice tried by Mr. A. Cooper is the only one in favour of which facts and actual experience can be adduced; and, if we except the caſes publiſhed by this gentleman, we have no inſtance on record of a ſpina bifida being cured or benefited.

When the diſeaſe does not admit of the radical or palliative cure, the ſurgeon ſhould inſtruct the friends of the patient to keep the tumour out of the way of every thing that has a tendency to make it inflame and ulcerate; and, if any thing at all is done, the ſwelling ſhould be tenderly bathed every now and then with ſpirituous and mildly aſtringent lotions, with a view of averting inflammation and ulceration of the ſkin. Firſt Lines of the Practice of Surgery, by S. Cooper, edit. 3.

Spina *Burgi*, in *Botany*, a name uſed by ſome authors for the *alaternus*, or ever-green privet, a garden ſhrub, the fruit of which is a mild aſtringent.

Spina *Ventoſa*, in *Surgery*, a caries or abſceſs of the internal part of a bone. Spina was a term applied by the Arabian writers, becauſe the diſeaſe occaſioned a pricking in the fleſh; and the epithet ventoſa was added, becauſe the part affected communicates a feel as if it contained air. Spina ventoſa is often employed ſynonimouſly with white-ſwelling. See White-swelling.

SPINACH, or Spinage, in *Botany*. See Spinacia.

Spinach is ſometimes cultivated in the field for the advantage of the ſeed. The different ſorts of it are raiſed in this manner, in order to ſupply the demand for the different kinds of ſeed.

The land for theſe crops is finely prepared by different ploughings and harrowings in the early ſpring, and a little well rotted dung intimately blended with the ſoil, where the land is not of a good quality.

The different ſorts of ſeed are then ſown in ſmall furrows made for the purpoſe, in the ground, either by the hand-hoe, or by means of a drill for this uſe, at the diſtance of from about twelve to fourteen inches from each other; the prickly ſort of ſeed being uſed in the proportion of ſix gallons to the acre, and the round ſort in that of four to the ſame quantity of land.

Some time in the early part of March, when the plants have advanced ſo as to have leaves of about one or two inches in length, they are thinned out by the hoe to the diſtance of four or five inches. The rows of plants are always kept well moulded up both before and after the period of thinning, and the whole crop preſerved in a perfectly clean ſtate from weeds. As ſoon as the crop has reached the time of being in full bloom, the greater part of the male plants are drawn out, by the hand, from among the others, by which means the female plants are allowed more room, light, and air to grow in, and thereby to perfect their ſeed in a better and more full manner. The plants which are thus drawn out anſwer in a very profitable manner in the feeding of young pigs, and they may probably be given to ſome other ſorts of animals with advantage.

When the crop becomes quite ripe, it is pulled up, and the ſeed either threſhed out on a cloth in the field, or the whole carried to the barn, to be afterwards threſhed out. See Spinacia.

The produce is uſually from about two to five quarters on the acre, according as the ſeaſon and other circumſtances are leſs or more favourable.

The cultivation of ſpinach for ſeed in the field often turns out very advantageouſly, but it is attended with ſome degree of uncertainty, as is the caſe with moſt crops of this nature.

It is a crop which is much grown in the iſle of Thanet, and in Eaſt Kent, in order to ſupply ſeed for the London ſeedſmen.

Spinach, *Strawberry*. See Blitum.

Spinach, *Wild*, in *Agriculture*, the name of a weed, as the gooſe-foot. It is very troubleſome in ſome ſorts of land.

SPINACHIA, in *Ichthyology*, a name given by ſome authors to our common ſtickleback, or banſtickle, more uſually known among writers by the names *pungitius*, or *aculeatus piſciculus*. See Stickle-*Back*.

SPINACIA, in *Botany*, a name of dubious origin, but the moſt general and probable etymology deduces it from *ſpina*, a thorn, on account of the prickly or ſpinous integument of the fruit.—Linn. Gen. 520. Schreb. 688. Willd. Sp. Pl. v. 4. 766. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 385. Tournef. t. 308. Juſſ. 85. Lamarck Illuſtr. t. 815. Gærtn. t. 126.—Claſs and order, *Dioecia Pentandria*. Nat. Ord. *Holeraceæ*, Linn. *Atriplices*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth inferior, deeply cloven into five concave, oblong, obtuſe ſegments. *Cor.* none. *Stam.* Filaments five, capillary, longer than the calyx; anthers oblong, twin.

Female, *Cal.* Perianth inferior, of one leaf, permanent, cloven into four, alternately ſmaller ſegments. *Cor.* none. *Piſt.* Germen inferior, roundiſh, compreſſed; ſtyles four, capillary; ſtigmas ſimple. *Peric.* none, except the ſurrounding, hardened calyx, which encloſes a ſolitary, roundiſh *ſeed*.

Obſ. The fruit is occaſionally round, but generally beſet with two or four horns or ſpines.

Eſſ. Ch. Male, Calyx deeply five-cleft. Corolla none.

Female, Calyx four-cleft. Corolla none. Styles four. Seed ſolitary, within the hardened calyx.

1. S. *oleracea*. Garden Spinach. Linn. Sp. Pl. 1456. "Schkuhr. Handb. v. 3. 469. t. 324." (Spinachia; Ger. Em. 330.)—Fruit ſeſſile.—Native place of growth unknown. It was cultivated in Great Britain ſo long back as the year 1568, and flowers throughout the ſummer. *Root* annual. *Stem* one or two feet high, herbaceous, branched, hollow. *Leaves* arrow-ſhaped. *Male flowers* herbaceous, in long ſpikes, abounding with pollen. *Female flowers* on a ſeparate plant, in cluſters on the ſtalks at every joint, herbaceous, ſmall. *Seeds* roundiſh, unarmed, ſubject to vary with regard to ſpines.

There are two or three varieties of the garden ſpinach, one called *prickly*, another *ſmooth*; differing in the ſize and ſhape of the leaves, and in their ſeeds being more or leſs prickly.

This plant does not appear to have been known to the ancients. It is called Hiſpanac by Arabian phyſicians, and has been ſo long and generally cultivated in Spain, as to have obtained the name of *Hiſpanumolus*. A conjecture is propoſed by profeſſor Martyn reſpecting the introduction of this plant into Spain by the Saracens.

2. S. *fera*. Wild Spinach. Linn. Sp. Pl. 1456. (S. foliis ex deltoideo-ovatis, ſubſinuoſis, capſulis in orbem diſpoſitis; Gmel. Sib. v. 3. 86. t. 16.)—Fruit ſtalked.—Native of Siberia, in damp, unfrequented places.—*Root* annual, whitiſh. *Stem* nearly two feet high, branched, erect. *Leaves* ſtalked, triangular or ovate, occaſionally ſinuated, obtuſe. *Male flowers* in cloſe heads, near the *females*, or in ſolitary, interrupted ſpikes. *Fruits* axillary, three or more, on ſtalks of their own length, ovate or obovate, obtuſe, ſlightly keeled on each ſide, ſmooth, very obtuſe.

Spinacia, in *Gardening*, contains a plant of the annual culinary kind, of which the ſpecies cultivated is the garden ſpinach (S. oleracea.)

There are varieties of this which differ in the ſize and ſhape of the leaves, and the greater or leſs pricklineſs of the ſeeds; as the triangular with prickly ſeeds, in which the leaves are triangular and ſharp arrow-pointed, the ſeeds ſomewhat armed with ſhort ſpines; the round with ſmooth ſeeds, which has ovate thick leaves, not angular at their baſe; both the ſtalks and leaves are much more fleſhy and ſucculent than in the other ſort; and the ſeeds are ſmooth, without any ſpines. Of this alſo there are two or three ſub-varieties, differing in the ſhape, thickneſs, and ſize of their leaves.

In each of the principal ſorts there are variations in the leaves, as to their form and magnitude, but the broadeſt and thickeſt-leaved ſorts are far the beſt in quality. Thoſe with the moſt thick and ſtocky leaves, of a ſtrong dark green colour and luxuriant growth, are commonly ſuppoſed the moſt valuable ſort of the round kind.

Method of general Culture.—In theſe plants it is effected only by ſeed, by ſowing it every year in ſpring and autumn; the former furniſhing the main ſpring and ſummer crops; and the latter the winter, and thoſe for early ſpring uſe. The prickly ſort is the beſt for winter crops, and the round for the ſummer ones.

The ſeed ſhould be ſown at ſeveral intervals of time from January till Auguſt, as every month, three weeks, or fortnight, according to the earlineſs or advanced period of the ſeaſon, ſo as to obtain a regular ſucceſſion moſt part of the year. The general ſpring crop ſhould be ſown in March, and the general winter crop about the beginning of Auguſt.

But in the ſpring ſowings, as the crops in the very early ſowings in January run ſoon to ſeed, a moderate quantity ſhould only be ſown. However, in the autumn ſowings, as the plants do not run the ſame year, good full crops, to ſtand for winter and early ſpring uſe, may be put in.

Theſe plants ſucceed in any common ſoil of the kitchen-garden; but the richer in dung the better; always chooſing an open ſituation, not too near low ſpreading trees, &c. as they never ſucceed in cloſe or ſhady places, in which they are always drawn up weak, and ſoon run to ſeed without attaining perfection: a warm border may be proper for the early crops; but for the main crops in general, the open quarters are the moſt ſuitable, though a broad warm-lying border may alſo be proper for ſome part of the later ſown winter crops occaſionally, for the purpoſe of having the advantage of a little ſhelter of the fence, and benefit of the ſun during the winter ſeaſon; and freſh ſeed ſhould be procured for each ſowing, as this will be found of great importance in the free growth of the plants: for the autumn ſowings of the winter crops, it is of advantage to procure new ſeed of the ſame year.

And after the ground has been properly dug, the ſeed may either be ſown broad-caſt, and raked in, or in ſhallow drills a foot aſunder; though broad-caſt is the moſt expeditious, and probably the moſt proper method for the growth of the crops in the product of large full leaves; ſowing it all over the ſurface moderately thin, either in one continued plat, and trodden down evenly, if light ground, and raked in with a large rake or light harrow; or the ground may be divided into four or five-feet wide beds, with foot-wide alleys between each, eſpecially for the early and winter crops in moiſt ground; the ſeeds being ſown as above, raking them in evenly: drill-ſowing may alſo be occaſionally practiſed with convenience and advantage, in which the drawing of the drills ſhould be performed with a hoe flatways, near an inch deep, and ten or twelve inches aſunder, then ſcattering the ſeeds thinly along them, raking the earth over full half an inch deep; which mode is often very proper in ſowing between other crops, as between wide rows of beans, peas, cabbages, &c. as it admits of hoeing up the weeds between the rows with facility; and if ſown thin, and the plants be thinned out properly, they grow large and fine, and the produce is very conveniently gathered. It may likewiſe be ſown in wide drills alone, about a foot diſtance, for a diſtinct full crop: or in rows two feet aſunder, to admit of intercropping in the intervals, with rows of cabbages, beans, and other things occaſionally. In theſe ſowings the ſeeds ſhould be ſcattered moderately thin, and the plants be afterwards thinned out to three inches diſtance at leaſt, the ſeeds being directly raked regularly in: and when ſown broad-caſt all over the ſurface, if in light looſe land, and a dry warm ſeaſon in the advanced part of ſpring, or in the ſummer and autumn, it may be proper firſt to tread the ſeed evenly down, then raking it in effectually with a large rake. The ſeeds moſtly come up in a fortnight; or perhaps, if ſown very early in ſpring, it may be three weeks or a month before they appear.

In reſpect to the after-culture of the crops, when the plants have three or four leaves an inch broad, they ſhould be thinned out and cleared from weeds, either by hoe or hand; but the former is the moſt eligible, eſpecially for the broad-caſt ſown crops; chooſing dry weather, and cutting out the plants to three or four inches diſtance, together with all the weeds in every part; but the above diſtance is ſcarcely ſufficient, unleſs it is intended to begin thinning out the plants for uſe while young: in other caſes it is adviſable to hoe them out ſix or eight inches aſunder, eſpecially the ſpring and ſummer crops of the round ſpinach, which, having proper room, will grow very large, and ſpread its broad leaves widely, and does not run to ſeed ſo ſoon as if left cloſe. When the ſpring and ſummer-ſown crops are left too cloſe, they are apt to draw up weak, and ſoon go to ſeed. The winter crops of triangular or prickly ſpinach, it will be ſufficient in moſt caſes to thin out finally to three or four inches diſtance.

Theſe crops are often ſown in ſpring with other crops, for the ſake of cropping the ground to the beſt advantage; but it is beſt when performed alone in moſt inſtances.

They may, however, in ſome caſes, be put in between the rows of particular plants with ſome utility in the way of ſaving ground, where that is material, as between young cabbage and cauliflower plants, which have been finally ſet out at wide diſtances for main crops, as well as in the large intervals of pea and bean crops, eſpecially when of the low or dwarf kind, and between ſome other ſorts of general rowed crops with wide ſpaces. The ſpinach ſeed, in theſe circumſtances, is moſtly beſt put into the ground in ſingle or double drills in the middle parts, according to the diſtances of the rows of the other plants; but it is ſometimes ſown in the broad-caſt manner over the whole ſurfaces of the intervals, and raked in. And it is occaſionally ſown over all the piece of ground in mixture with ſhort-top radiſh ſeed, and raked in; after which, either immediately or in a ſhort ſuitable ſpace of time, the plants or other crops are planted out or ſown in their regular modes. The ſowing of ſpinach ſeed in this way, commonly takes place in the early parts of February and the following month, and is practiſed upon the borders, as well as the large quarters where ſuch main ſpring crops are to be grown and cultivated. The plants or other crops in this mode growing quickly, have ſoon the advantage of the mixed crops between their rows, though the ſmall plants of theſe kinds are not injured or retarded in their growth thereby, as they are ready to be gathered and removed for uſe long before the main crops have any hurtful tendency.

Immediately on the removal of ſuch ſmall crops, the intervals of the rows are hoed over to looſen the earth, which is then drawn up to the ſtems of the plants or other crops. Theſe methods of cropping are, however, only to be uſed in ſuch caſes as the above.

When the plants have leaves two or three inches broad, they may be gathered. The method of which is, either by cutting them up with a knife wholly to the bottom, or drawing and cleaning them out by the root, if the crops want thinning; or only cropping the large outer leaves, the root and heart remaining to ſhoot out again. With the ſpring crops, when the plants want thinning, they may be cut up wholly to the root, thinning them out where thickeſt in a gradual manner, ſo as to leave the ſtanding plants at leaſt ſix or eight inches diſtant to grow to perfection, which, when beginning to ſhoot for ſeed, may alſo be cut up wholly to the bottom: and in the winter crops, if the plants ſtand too cloſe at firſt, ſome may be thinned out quite to the bottom, afterwards the larger outer leaves only muſt be cropped in the winter and early part of the ſpring; but when the ſpring is more advanced, and the plants grown large and require thinning, or when they begin to run to ſeed, cutting them up to the bottom in a thinning order is the beſt method.

Some of the beſt of the different ſorts of plants ſhould be left in the ſpring to ſtand for ſeed, which ſhould be collected, when well ripened, in the manner directed below.

Culture in the early and ſucceſſion Crops.—In raiſing early crops of this ſort, as well as thoſe which are to come in regular ſucceſſion, during the beginning of the ſpring and the firſt part of the ſummer ſeaſon, it will be neceſſary to commence and continue the ſowing of the ſeed at two or three different times in the month of January, when the weather is mild and open, chuſing the moſt dry and warm ſituations that can be found for the purpoſe, and only putting in ſmall quantities in each of ſuch ſowings, as the crops are extremely liable to be deſtroyed or to run to ſeed. In the ſucceeding month it will likewiſe be proper to continue the ſowings in a more full manner as to the quantities, at two or three additional different periods, in almoſt any open places of the garden, by which means full ſucceſſions may be provided, for ſome length of time, to follow the crops of the firſt winter ſowings, which will now ſoon run up to ſeed, theſe ſowings coming in much about the ſame time. In the two months which follow the laſt, it will ſtill be proper to proceed or go on with the ſowing of this ſort of ſeed every ten days, or fortnight, making uſe of open but rather cooler ſituations. By this means regular ſupplies will be provided for the concluding ſpring and beginning ſummer months.

And in caſes where conſtant ſucceſſions of crops of this kind are wanted the whole of the ſummer ſeaſon, it will be requiſite and proper to continue the repetition of the ſowings every fortnight during the months of May, June, and July, as the plants in theſe ſowings very quickly run up for ſeed. The moſt moiſt ſpots which the garden affords ſhould now be ſelected for ſuch crops, they being free and open. It is alſo advantageous in the ſummer ſowings to have ſhowery weather for performing the work in, when it can be had. The ſeed ſhould be ſown rather thin, when in the broad-caſt method; and in the drill mode to only the depth of about an inch. The plants are to be kept pretty well thinned, in order to prevent their drawing up to ſeed. The ſowings which are made in the laſt of theſe months, will continue the crops in ſucceſſion, until they are ſucceeded by thoſe of the winter ſowings.

In theſe caſes the ſpinach is ſometimes not ſuffered to grow large, but cut in its young growth, allowing the bottom parts to grow again.

In the after-culture there is nothing material in theſe crops, beſides that which is neceſſary in the general ones.

Culture in the late or winter Crops.—In theſe caſes the ſeed is ſown to the moſt advantage for the ſucceeding crops towards the end of the firſt week in Auguſt, the beginning of the ſecond, and the middle of the third, according to the nature, ſituation, and ſtate of the ground, as they are the moſt prevented in common from running up too early to ſeed, while they get a little growth, and become ſomewhat forwarded and ſtrong before the winter weather ſets in. It is beſt when the ſowings can be performed in rather moiſt ſhowery times, as when it is done at dry hot periods, the ſeed is apt to ſprout and come up in an irregular manner, the plants appearing in a ſtraggling ſparing ſtate. Theſe crops ſhould conſtantly have, as much as poſſible, open ſituations, which lie dry at this ſeaſon of the year, and which have ſunny expoſures.

The ſeed is to be immediately ſown on the freſh newly turned up ſoil, either over the whole ſurface, or in the bed manner, which is more convenient for the cultivation and collecting of the produce. In ſome places, a ſlight ſprinkling of the brown Dutch and common cabbage lettuce ſeed, or other ſimilar ſorts, are ſown along with this kind of ſeed in theſe crops, in order to ſtand for culling out during the winter and early ſpring months. The ſeed is to be covered and trod in directly after being ſown.

Theſe late crops are alſo occaſionally, though rarely, ſown in the drill manner, but the former methods are more ſuitable in theſe caſes, where gradual thinning is to be practiſed with the crops, which is by much the beſt ſort of cultivation for having ſuch crops in fine perfection.

Where large crops of the winter kind are raiſed, as in market gardens, early cabbages are ſometimes planted out with theſe crops in wide rows, as three or four feet apart. The ſetting out of theſe plants takes place in October or the following month. At theſe diſtances no injury is done to the ſpinach crops by the growth of the cabbage plants, and in the early ſpring, the ſpinach being wholly cleared away for uſe, a full forward cabbage crop is left, and the moſt is made of the land and time.

The plants in theſe late crops want thinning and clearing from weeds early in their growth, as when leſs than an inch in the breadth of the leaves, which may be done by the uſe of the hoe in a dry time, leaving the plants not more than three or four inches apart, as ſome may be gradually afterwards thinned out for uſe, ſo as to let them ultimately ſtand about five inches from each other; the leaves are after this only to be gathered for uſe, during the whole winter ſeaſon, the larger outer ones being alone taken, the ſmaller inner ones being always left to expand themſelves by degrees, in their turn, and afford regular ſucceſſional ſupplies until the end of the ſpring, at which time, when the plants begin to grow large and crowd each other, or to ſhoot up for ſeed, they may be wholly cleared away.

In theſe crops much attention is neceſſary to keep them clear from weeds, by frequent hoeing and hand-weeding, being careful to remove chick-weed, which is always liable to infeſt theſe crops much in winter. All the large weeds ſhould be wholly removed from the ground, as if left they do great injury, and not unfrequently take root again.

As the ſpring advances, the ſurface of the ground ſhould be lightly hoed among and about the plants, taking a fine mild dry day for the purpoſe; which will greatly promote the growth of them, and by which they will ſoon ſhoot out ſtrongly, becoming further in a fine ſtate of perfection for uſe. The large outer leaves are ſtill only to be gathered, except where the plants ſtand too thick in the crops.

Saving Seed.—The ſeed being perfectly ripe in the plants which are left for this purpoſe, which ſhould always be thoſe of the moſt ſtocky growth, and which have the largeſt, the moſt expanded, and the thickeſt leaves, is eaſily known by its turning of a brown colour, and hardening in the tops of the ſeed-ſtalks. The plants of the winter crops moſtly run up firſt to form ſeed-ſtalks, being ſoon, however, followed by thoſe of the ſpring-ſowings, and they are commonly loaded with plenty of well-ripened fertile ſeeds about the cloſe of July or beginning of the following month. In this ſtate the ſtalks are to be pulled up and ſpread out to dry for a few days, turning them as it may be neceſſary, in order to fully dry and harden the whole of the ſeed in a proper manner. They are then to be beat or threſhed out from the ſeed-ſtalks upon a cloth, and put up in bags to be kept in a dry ſituation for uſe.

The ſeed which is newly ſaved is excellent for ſowing the winter crops with, provided it be ripe in due time. It will, however, remain perfectly good until the following year's ſowing, but ſhould not be truſted to when more than one year old, as new ſeed is always of material importance in this culture.

It is proper and neceſſary, in raiſing the ſeed of the different varieties, to have the plants of the different ſorts, in different ſituations, at ſome conſiderable diſtance from each other, in order to prevent injury and degeneracy, by the farina of one ſort being diſperſed over the other.

The plants of the different kinds are readily diſtinguiſhable when they are in flower, and the male plants, after they have diſperſed their farina, are in ſome diſtricts, where the providing of this ſort of ſeed is an object, drawn out, ſo as to leave more room for the ſeed-plants. See SPINACH.

SPINADESCO, in *Geography*, a town of Italy, in the department of the Upper Po; 4 miles W. of Cremona.

SPINÆ, in *Ancient Geography*, a ſtation in the 13th and 14th Iter of Antonine's Itinerary of Britain, between Durocornovium or Cirenceſter and Calleva or Silcheſter in the former, and Cunellio or Marlborough and Calleva in the latter, and correſponding to Speen, near Newbury, (which ſee.) The number of miles between Cirenceſter and Speen being only 15, which gives too ſmall a diſtance, Dr. Stukeley ſuppoſes that a ſtation is omitted between theſe two places; but Mr. Horſley conjectures, that the numerals oppoſite to Spinis ſhould have been 35.

SPINAL ARTERIES, in *Anatomy*, are two arteries, one anterior and one poſterior, both produced by the vertebrales; each of which, as ſoon as it enters the cranium, ſends out a ſmall branch, by the union of which the poſterior ſpinalis is formed. Afterwards the vertebrales advancing on the apophyſis baſilaris, or production of the occipital bone, detach backward two other ſmall branches, which likewiſe meet, and by their union form the ſpinalis anterior. Theſe ſpinal arteries run down on the fore and back ſides of the medulla ſpinalis, and by ſmall tranſverſe ramifications, communicate with thoſe which the intercoſtal and lumbar arteries ſend to the ſame part. See ARTERY, BRAIN, and SPINE.

SPINAL *Marrow.* See MEDULLA *Spinalis*, MEDULLARY *Syſtem*, and BRAIN.

SPINAL *Muſcles*, are thoſe vertebral muſcles which are wholly fixed in the ſpinal apophyſis. See MUSCLE and SPINE.

SPINAL *Nerves.* See NERVE and SPINE.

SPINAL *Apparatus*, a machine for affording ſupport to the ſpine, and imagined by certain practitioners to be uſeful in caſes of diſeaſe and diſtortion of the vertebræ.

SPINALIS, in *Anatomy*, a muſcle on the ſide of the neck, ariſing from the five ſuperior proceſſes of the vertebræ of the thorax, and the inferior of the neck; and which in its aſcent, becoming more fleſhy, is inſerted into the inferior part of the vertebræ of the neck laterally. It ſerves to draw the neck backwards. See SPINE.

SPINALIS *cervicis*, a name given by Albinus to a muſcle of the neck, called by Fallopius the *tertium par muſculorum dorſi*, and by Cowper and Morgagni, *ſpinalis colii.*

This is the muſcle, which the French anatomiſts call *les vertebraux externes du demi-epineux, ou le tranſverſaire epineux ducal.*

SPINALES *colli minores*, muſcles lying between the ſix ſpinal apophyſes of the neck, and between the laſt of the neck and firſt of the back; being inſerted in theſe apophyſes by both extremities on one ſide of the poſterior cervical ligament, which parts them from thoſe of the other ſide. They are likewiſe termed *interſpinales.*

SPINALIS *dorſi*, a name given by Albinus to a muſcle of the back, figured by Euſtachius, *Tab.* 37, and called by Fallopius *quinti paris dorſi muſculorum pars implantata in ſpinas vertebrarum thoracis.*

Others, as Spigelius, have called it a part of the ſemi-ſpinatus, and others a part of the longiſſimus dorſi. The French have named it *le grand epineux de dos.*

SPINALIS *dorſi major*, a pretty long and ſlender muſcle, lying upon the lateral part of the extremities of the ſpinal apophyſes of the back. It is compoſed of ſeveral muſcular faſciculi of different lengths, which croſſing each other, are inſerted laterally by ſmall tendons in the ſpinal apophyſes from the ſecond, third, or fourth vertebræ of the back; and ſometimes, though ſeldom, from the laſt of the neck, or firſt of the back, all the way to the firſt or ſecond vertebræ of the loins, with ſeveral irregular decuſſations, which vary in different ſubjects. The longeſt faſciculi are all a little incurvated, and the whole muſcle terminates in points at its ends, but is conſiderably broad in the middle. It communicates by ſome fibres with the longiſſimus dorſi and ſemi-ſpinalis, and ſends off faſciculi to ſeveral tranſverſe apophyſes of the back, from the fourth to the eleventh. It is called by ſome ſemi-ſpinalis, but very improperly. See MUSCLE and SPINE.

SPINALIS, *ſemi*, *colli*, and *dorſi*. See SEMI-SPINALIS.

SPINALES *dorſi minores*. Theſe muſcles are of two kinds; ſome go laterally from the extremity of one ſpinal apophyſis to another, being often mixed with the ſhort faſciculi of the ſpinalis major; the reſt lie directly between the extremities of two neighbouring ſpinal apophyſes, being ſeparated from thoſe on the other ſide by the ſpinal ligament. Theſe are ſmaller and thinner than thoſe of the neck, and are properly enough termed *interſpinales*. See MUSCLE and SPINE.

SPINALES *et tranſverſales lumborum*. There are ſome faſciculi which run up from the ſuperior falſe ſpines of the os ſacrum to the lower ſpinal apophyſes of the loins, which may be looked upon as ſo many *ſpinales lumborum majores;* and there are alſo ſome *ſpinales lumborum minores* between the ſpinal apophyſes of the loins, and *tranſverſales minores* between the tranſverſe apophyſes, which are ſometimes of a conſiderable breadth. See SPINE.

SPINALIS *Medulla*. See MEDULLA, &c.

SPINA-LONGA, in *Geography*, a ſea-port town and citadel, ſituated near a cape of the ſame name, on the iſland of Candia, with a good harbour, formerly the ſee of a biſhop; 30 miles E. of Candia. The harbour is formed by a peninſula,

ſula, which ſecures it from the eaſterly winds. Its entrance faces the N.N.E., but it is ſheltered and protected by an iſlet, on which the Venetians had built a fortreſs, ſimilar to that of Suda. For a long time the Turks made fruitleſs attempts to render themſelves maſters of this fortreſs; and it was not till the beginning of the laſt century that the Venetians permitted them to take poſſeſſion of it. N. lat. 35° 13′. E. long. 25° 42′.

SPINARELLA, in *Ichthyology*, a name given by Bellonius, and ſome other authors, to the little fiſh called by us the *leſſer ſtickleback*. In the Linnæan ſyſtem, this is a diſtinct ſpecies of the gaſteroſteus.

SPINATUS, in *Anatomy*, a name given by Riolanus, and others, to a muſcle of the neck, called by Albinus *ſpinalis colli*, and by Winſlow, and the other French writers, *les vertebraux externes du demi-epineux, ou tranſverſaire epineux du col.* See Spinalis and Transversalis.

SPINCOURT, in *Geography*, a town of France, in the department of the Meuſe, and chief place of a canton, in the diſtrict of Montmedy. The place contains 466, and the canton 9948 inhabitants, on a territory of 287½ kiliometres, in 27 communes.

SPINDLE, in *Mechanics*. See *Double* Cone, and Mensuration.

The axis of the wheel of a watch or clock is called the ſpindle, and its ends the pivot.

Spindle, *Parabolic*. See Pyramidoid.

For the method of finding its ſolidity, ſee Solidity.

Spindle, in *Sea Language*, a ſort of iron-pin, tapering at the upper end to a point. It is uſed to ſtick into the upper end of the top-gallant maſt, ſo as to carry a vane, which, turning thereon horizontally, will ſhew the direction of the wind. It is uſually crowned with a globular or conical piece of wood, called the *acorn*, which prevents the vane from being blown off.

Spindle alſo denotes the lower end or foot of the capſtan, which is ſhod with iron, and becomes the pivot or axis, upon which it turns in the ſaucer. See Capstan.

Spindle, in *Mining*, a piece of wood faſtened into either ſtow-blade. See Stows.

Theſe ſtows give a miner, or any other perſon that owns them, as good a right to a meer or meers of ground, (ſo that every meer have a pair of ſtows ſet on them,) as a deed of conveyance doth to any purchaſer.

Spindle-*Shell*. See Trumpet-*Shell*.

Spindle-*Tree*, in *Botany*. See Euonymus.

It is generally ſuppoſed that the euonymus of the ancients is the ſame plant that we at this time call by this name. The words of Theophraſtus have probably given occaſion to this opinion; as they ſound at firſt reading like words expreſſing the characters of the fruit of this tree; but on a cloſer inſpection, they will be found to expreſs a fruit of a very different kind. This author ſays, that the fruit of the euonymus is like the pod of the ſeſamum, marked with four protuberant ribs, and hard within, and divided into places for four orders of ſeeds. It is plain by this, that as their ſeſamum bore an oblong pod marked with four ribs, ſo as to ſeem of a quadrangular figure, ſo did their euonymus, and that in this long pod there were four orders of ſeeds, each of theſe orders containing a great many ſeeds. Now the fruit of our euonymus is ſhort and not at all like a pod, and contains only four ſeeds, and not four orders of ſeeds; there is alſo this farther proof of our euonymus not being that of the ancients, that our's is a wholeſome food to cattle, and they are very fond of cropping it whenever they can reach it, and never get any hurt by it; whereas the euonymus of the Greeks was poiſonous to cattle, according to Theophraſtus. See Fusanus and Tetrastoechon.

Spindle-*Tree, Baſtard*. See Kiggelaria.

SPINDLING, in *Agriculture*, the act of running to ſeed in plants of the grain and other kinds. A great deal, in this buſineſs, depends upon the manner in which the plants are cultivated.

SPINE, in *Anatomy*, (the vertebral or ſpinal column; the back-bone, in common language; ſpina dorſi,) is the articulated bony pillar at the back of the trunk, forming the foundation or baſis of ſupport and connection to all the other parts of the frame. It is placed perpendicularly in the body, ſuſtaining the head by its upper extremity, while its lower end reſts on the pelvis. The bones of the cheſt, to which the upper extremities are connected, are fixed to its ſides; while the oſſa innominata, or the great bones, to which the lower limbs are articulated, are immovably united to it below. It is the point of attachment and ſupport, in front, for the viſcera of the thorax and abdomen, and for the great trunks of the blood-veſſels. We may thus regard it as the central and moſt eſſential piece of the ſkeleton; as the centre of motion for the head and limbs; and the baſis of ſupport for all the great internal organs. Again; the bones which compoſe it give attachment to the principal muſcles moving the head, the ſhoulders, and the arms, to thoſe which act upon the trunk, and to ſome part of the abdominal muſcles, and of thoſe which move the lower limbs. Further, it conſtitutes a canal, which receives and protects the medulla ſpinalis, and gives iſſue to the various nerves proceeding from that organ to the trunk and limbs. The importance of the ſpine, on all the accounts juſt enumerated, is ſo great, that it conſtitutes a leading character, modifying all the other details of organization in the animals which poſſeſs it. Hence the primary diviſion of the animal kingdom into vertebral and invertebral animals, adopted by the great modern naturaliſts, with Lamarck and Cuvier at their head, is founded on the preſence or abſence of the vertebral column.

The ſpine is formed of twenty-nine pieces of bone, ſtrongly articulated to each other, and placed in ſucceſſion from above downwards. The twenty-four upper ones are called vertebræ, and are farther named cervical, dorſal, and lumbar, according as they occupy the neck, back, or loins: there are ſeven of the firſt kind, twelve of the ſecond, and five of the laſt. The five other pieces of the column are the ſacrum, and the four oſſa coccygis, which form the back of the pelvis; the firſt being articulated to the twenty-fourth vertebra, and the latter to the end of the ſacrum and to each other.

The form of the ſpine is ſymmetrical; but the two halves do not always correſpond accurately in the healthy ſtate, and the deviations are ſtill more remarkable in diſeaſe. As the weight to be ſuſtained by this bony column increaſes conſtantly from above downwards, the bulk of the vertebræ, and, conſequently, the ſtrength of the pillar, increaſe alſo in the ſame direction, with a trivial exception or two, which will be noticed afterwards. In the attitude of ſtanding, the vertebræ are all ſituated horizontally; their proceſſes, however, deviate in various ways from this direction. They are diſtinguiſhed numerically in the different regions, excepting the firſt and ſecond cervical, which are commonly called atlas and vertebra dentata or axis. The general configuration of theſe bones is the ſame throughout; they are formed on a common plan, but this plan is modified in each diviſion by circumſtances peculiar to the different regions. The diſtribution of them into three claſſes is principally founded on theſe modifications: the claſſes are indeed named from their poſition, but the diverſities of their external forms characterize them. We ſhall firſt deſcribe the general form, and then notice the particular modifications of the vertebræ.

General Form of the Vertebræ.—They conſiſt of various irregular and prominent portions, ſeparated by different intervals, and united by different plates. The principal part of the bone in ſize is the anterior prominence, called the body; it is cylindrical or oval, and repreſents the ſection of a cylinder, being terminated above and below by two flat ſurfaces, which give attachment to the fibro-cartilages occupying the intervertebral ſpaces. This body of the vertebra forms in front a greater or leſs convexity, in which we obſerve a kind of tranſverſe depreſſion, bounded by two prominent edges; it is plane, or a little concave, behind, where it correſponds to the vertebral canal: in both ſituations there are ſeveral apertures for the paſſage of blood-veſſels into the ſubſtance of the bone. At each ſide the body is continuous with the reſt of the bone by a kind of pedicle.

A large oval or triangular opening, called the ring or foramen, and contributing to the formation of the vertebral canal, which holds the medulla ſpinalis, is placed immediately behind the body. Directly behind this opening is the ſpinous proceſs, varying in form and direction in the different regions, projecting backwards beyond the level of the bone, and ſeparated from the correſponding proceſſes immediately above and below it, by a ſpace filled either with muſcles or ligaments.

Such are the parts of each vertebra as come into notice on the middle line of the bone, from before backwards. When we view it laterally, we obſerve, 1ſt, two notches, a ſuperficial one above and a much deeper below, excavated on the pedicle, which connects the body to the articular and tranſverſe proceſſes, and forming, when the bones are joined, thoſe lateral foramina of the vertebral canal, through which the nerves are tranſmitted; 2dly, two articular or oblique proceſſes, a ſuperior and an inferior, furniſhed with cartilaginous ſurfaces, by which they are articulated to the correſponding proceſſes of the bones above and below, and having this ſurface turned backwards or inwards in the ſuperior, forwards or outwards in the inferior; ſo that each vertebra is mechanically locked in its ſituation by the two vertebræ immediately above and below it; its ſuperior articular proceſſes being overlapped by the inferior ones of the bone above, while its inferior proceſſes overlap thoſe of the bone next below: 3dly, a tranſverſe proceſs, directed horizontally, as its name indicates, longer or ſhorter in the different regions, and giving attachment to muſcles; and 4thly, a flattened plate, united to that of the oppoſite ſide to form the ſpinous proceſs.

Particular Forms of the Vertebræ.—The various common circumſtances juſt enumerated are greatly modified in the different regions; it is principally in the middle of each region that we muſt examine theſe modifications, which, at either end, gradually approach to the characters of the neighbouring regions.

The Cervical Vertebræ.—Their number is very conſtantly ſeven; but inſtances are mentioned, in which there have been eight or only ſix. (See Euſtachius, Oſſium Examen, p. 210; and Columbus de Re Anatomica, p. 263.) The peculiarities of form are ſtrongly marked and diſtinct in this region. The firſt and ſecond too, in conſequence of their articulation to the head, differ widely from the others, and muſt therefore be deſcribed ſeparately.

The *atlas*, or firſt vertebra of the neck, deviates more than any other from the general type. It is very much expanded laterally, and its ring or foramen is very capacious. When we look at it in front, it ſeems to want the body, inſtead of which we find a ſmall bony arc, flattened in an oppoſite direction to that of the bodies of the other vertebræ, convex and riſing into a tubercle in front, concave behind, where it bears a ſmooth cartilaginous ſurface, articulated to the odontoid proceſs, thin above and below, where it is connected, by means of ligaments, to the occiput and ſecond vertebra. Immediately behind this bony arc is the large ring, larger in this than in any bone of the column, and conſiſting of an anterior ſmaller, and a poſterior larger diviſion, of which the diſtinction is marked by two protuberances, between which a tranſverſe ligament is extended. The front of the ring is filled by the odontoid proceſs; its back part is the beginning of the vertebral canal. Inſtead of the ſpinous proceſs, and of the laminæ which unite to form it, there is a poſterior bony arc, about twice as large as the anterior, riſing into a ſmall tubercle at the middle, where the ſpinous proceſs ſhould be, and bounding the vertebral canal behind. The edges of this arc have ligamentous connections above and below. Inſtead of articular proceſſes, the atlas poſſeſſes on each ſide, above, a large oval cavity, directed obliquely from behind forwards and inwards, covered by cartilage, croſſed by a notch, in which a ſynovial gland is placed, more elevated at its outer than at its inner edge, and correſponding to the occipital condyle, with which it is articulated; below, a large, circular, and nearly horizontal plane, covered by cartilage, and articulated to a correſponding plane of the ſecond vertebra. A very deep channel, ſometimes formed by a bony plate into a complete foramen, is placed immediately behind the ſuperior articular concavity; it is occupied by the vertebral artery, and the firſt cervical or ſub-occipital nerve. The inferior notch, contributing to the opening for tranſmitting the ſecond cervical nerve, is behind the inferior articular plane: thus the nerves, which in all the reſt of the ſpine go out in front of the articular proceſſes, paſs behind them in the atlas. The tranſverſe proceſs is very remarkable for its length, much exceeding that of any other cervical vertebra. It is formed by a ſlender anterior and poſterior root, between which the foramen for the vertebral artery is placed, uniting into a conſiderable obtuſe prominence. Thus the atlas, with the exception of the thick lateral parts, to which the occipital condyles are articulated, forms nearly a bony ring.

To the tubercle of its anterior arch the longus colli and the rectus capitis internus minor are fixed: to the tranſverſe proceſs, the rectus lateralis, the obliquus ſuperior and inferior, the levator ſcapulæ, the intertranſverſi, and the ſcalenus anterior. The rectus poſticus minor is fixed to the tubercle of the poſterior arch.

The *vertebra dentata*, axis, epiſtropheus, or ſecond vertebra of the neck, is diſtinguiſhed from all others by its odontoid or tooth-like proceſs, and by its large, ſuperior, articular planes. Its body exhibits above, inſtead of the uſual ſuperior ſurface, a large bony proceſs, called the dentiform, odontoid, or tooth-like, having a ſlightly convex cartilaginous ſurface in front, articulated to the back of the anterior bony arc of the atlas, a ſmall, concave, articular face behind, on which the tranſverſe ligament plays, and terminating above in a rather unequal obtuſe extremity, from which ligaments ariſe, connecting it to the lateral anterior portions of the foramen magnum. The anterior ſurface of the body of the axis has a middle line, on each ſide of which it is ſlightly hollowed for the longi colli: the poſterior, rough, and perforated by ſmall openings for blood-veſſels, forms part of the vertebral canal. The inferior ſurface gives attachment to the firſt intervertebral fibro-cartilage. The ring is as large in this as in the atlas. The plates of the ſpinous proceſs are broad and thick, and the proceſs itſelf is ſtrong and prominent, projecting conſiderably beyond thoſe of the ſucceeding bones. It is rough below, and ends behind either in an expanded knob, or in a bifurcated extremity. On each ſide of the tooth-like proceſs there is a large circular and nearly horizontal plane, for articulation with the atlas. The inferior articular proceſſes are ſimilar to thoſe of the other cervical vertebræ: they are oblique, placed behind the tranſverſe proceſſes, and have their articular faces turned forwards. The ſuperior notches for the nerves are behind the ſuperior planes; while the inferior are in front of the correſponding articular proceſſes. The tranſverſe proceſs is ſmall, and perforated for the vertebral artery by a foramen, which is directed obliquely upwards and outwards

The axis is united to the head, the atlas, and the third vertebra of the neck.

To its tranſverſe proceſs, the ſplenius capitis, levator ſcapulæ, ſcalenus, tranſverſus cervicis, longus colli, and intertranſverſi anterior and poſterior, are affixed: to the ſpinous proceſs, the rectus capitis poſterior major, the obliquus inferior, the ſemi-ſpinalis cervicis, the interſpinalis, and multifidus ſpinæ.

The five lower cervical Vertebræ.—The body is very ſmall, in compariſon to the proceſſes and the ring; it is flattened in front, and elongated tranſverſely, ſo that it is on a level nearly with the tranſverſe proceſſes, inſtead of projecting into a bony column in front of them, as it does in the other regions of the ſpine. It is rather thicker before than behind: its ſuperior ſurface is concave from ſide to ſide, riſing up laterally into two thin ridges, and rather ſloping off in front: the inferior preſents juſt the oppoſite conformation, ſo as to fit it to be received into the hollow of the vertebra below. We may notice, in front, a middle ſurface, correſponding to the anterior vertebral ligament, and two lateral ones, adapted to the longi colli. A ſmall articular ſurface is obſervable on each ſide of the lower edge of the body of the ſeventh, contributing to the cavity in which the head of the firſt rib is lodged. The ring for the ſpinal marrow is large and triangular, with the angles rounded. The ſpinous proceſſes are priſmatic, horizontal, and either bifurcated at the end, or flattened and marked with a groove. They vary conſiderably in their direction, degree of bifurcation. &c. Three of the four vertebræ immediately ſucceeding the axis appear very ſmall in compariſon to its ſpinous proceſs; but the ſpine of the ſeventh is large and prominent. The notches for the lateral foramina are placed in front of the articular proceſſes; and the ſuperior and inferior ones differ very little in depth. The articular proceſſes are oval in their figure, and directed obliquely: the ſuperior backwards and upwards, the inferior forwards and downwards. The tranſverſe proceſſes increaſe in ſize from the axis; there is a deep channel in the ſuperior ſurface of each, lodging the anterior branch of the correſponding cervical nerve; hence the extremities are bifurcated. Each is perforated at its baſe by a round hole for the vertebral artery; which has been obſerved ſometimes to be abſent in the ſeventh.

The ſeventh cervical approaches in all reſpects very nearly to the characters of the dorſal vertebræ.

The muſcles attached to the cervical vertebræ are the interſpinales; the intertranſverſi anteriores and poſteriores; the rectus anticus major; longus colli; ſcaleni, anterior medius and poſterior; cervicalis deſcendens; tranſverſalis colli; ſacrolumbalis; ſerratus poſticus ſuperior; rhomboideus minor; trapezius; ſplenius capitis; and part of the rhomboideus major.

The Dorſal Vertebræ.—Their number depends on that of the ribs: they are very ſeldom eleven; more frequently thirteen; in which latter caſe there are generally only four lumbar vertebræ. Their chief characteriſtics ariſe from the articulation of the ribs to this part of the column.

The body projects in front, when compared to the vertebræ of the neck: it is thick behind, and narrower in front. The upper and under ſurfaces are plane. It is convex in front, a little concave behind. It is longer, thicker, larger in all reſpects, and more cylindrical, in proportion as we deſcend. The body of the firſt, or even of the ſecond alſo, is flattened in front, like thoſe of the cervical; but the third, fourth, fifth, and ſixth, have the cordiform ſhape, being broad behind, and narrow in front; the ſeventh, eighth, and the reſt, are more and more cylindrical. Generally, the third and fourth are the ſmalleſt of all. At its lateral and poſterior part there is a ſmall articular ſurface above and below, of which the upper is the largeſt. Theſe cartilaginous ſurfaces form, with the correſponding ones of the neighbouring vertebræ, and the intermediate fibro-cartilages, the articular concavities, which lodge the heads of the ribs. Sometimes the firſt dorſal vertebra has an entire articular concavity at its upper edge, and a half cavity below: or the upper may be a half cavity alſo, the articulation being completed by the lower margin of the ſeventh cervical. In the eleventh and twelfth there is a ſingle cavity only, placed either at the upper edge or towards the middle of the bone, and receiving by itſelf the head of the correſponding rib. The ring is ſmall and circular. The plates are broad, thicker, and more perpendicular than in the neck; and they give origin to a very long ſpinous proceſs, which is priſmatic, pyramidal, broad at the baſis, and growing narrower at the oppoſite extremity, which is pointed, and directed obliquely backwards and downwards. The ſpinous proceſs of the firſt dorſal vertebra is thick, extended nearly horizontally, and ends in a flattened tubercle. The ſecond, and particularly the third, is more ſlanting; the upper margin more acute; and the extremity longer and more pointed. Theſe characters become more ſtrongly marked in the fourth to the ſeventh or eighth: they are very long, and pointed, the ſuperior edge is very acute, and the inferior ſurface is nearly flat; they ſlope ſo much, that they lie one over the other, in cloſe contact, while thoſe of the three upper and four lower ſtand quite apart. The effect which this arrangement muſt have in limiting the poſterior inflexion of the column is very obvious. In the four loweſt dorſal vertebræ, the depth of the ſpinous proceſſes, from above downwards, is increaſed; they are extended more horizontally, and the length of their points is diminiſhed. The ſpinous proceſſes of the dorſal vertebræ are ſeldom all arranged in the ſame perpendicular line: one may deviate to the right, another to the left, &c. The articular proceſſes are perpendicular, the ſuperior being directed backwards, the inferior forwards, excepting the inferior ones of the twelfth, which are turned outwards, to be adapted to the ſuperior proceſſes of the firſt lumbar vertebra.

The tranſverſe proceſſes are very thick, and conſiderably inclined backwards: this, together with the concavity of the column in the back, enlarges the ſpace for the reception of the lungs. When the ſpine is viewed laterally, the tranſverſe proceſſes of the dorſal are conſiderably behind the line of thoſe of the cervical or lumbar regions. Each of them has a ſmall plane, or very gently concave, ſurface, on the anterior part of its extremity, by which it is articulated to the tubercle of the correſponding rib. Theſe ſurfaces are directed upwards in the ſuperior vertebræ, downwards in the inferior. The tranſverſe proceſſes decreaſe conſiderably from the tenth to the twelfth; and the two laſt have no ſurface for articulation with the ribs.

The configuration of the twelfth dorſal vertebra differs very little from that of the lumbar.

To the vertebræ of this region the following muſcles are affixed: *viz.* ſplenius capitis and colli, trachelomaſtoideus, biventer cervicis, complexus, longus colli, tranſverſalis colli, ſemiſpinalis colli, ſemiſpinalis dorſi, multifidus ſpinæ, ſacrolumbalis, levatores coſtarum, intertranſverſales and interſpinales dorſi, latiſſimus dorſi, rhomboideus major, trapezius, ſerratus poſticus ſuperior and inferior.

The *lumbar vertebræ* are ſeldom ſix in number, and more rarely four. Their great ſize, which increaſes down to the laſt, diſtinguiſhes them from thoſe of the back and neck; while the thick fibro-cartilages, by which they are joined together, and the free ſpace between their ſpinous proceſſes, give them conſiderable power of motion. The bodies are large and cylindrical, with flat ſurfaces above and below, excepting the inferior, which is cut off obliquely, to accommodate it to the ſacrum, with which it is united to form the promontory: the ring is triangular, and larger than in the neck. The laminæ are thick and ſtrong, and form a large ſpinous proceſs, which is flattened laterally, terminating above and below in a thin edge, and forming a rounded end behind. That of the laſt is very ſhort, and ſometimes entirely wanting. The tranſverſe proceſſes are flattened, and rather turned backwards: it is ſhort in the firſt, increaſes in the ſecond and third, then again diminiſhes. The articular proceſſes are perpendicular; the ſuperior ſlightly concave, and the inferior proportionally convex. The former have their articular faces turned inwards and backwards; the latter outwards and forwards: the ſpace between the ſuperior is, therefore, neceſſarily more conſiderable than that between the inferior.

The following are the muſcles attached to the lumbar vertebræ; *viz.* interſpinales and intertranſverſales lumborum, ſpinalis dorſi, multifidus ſpinæ, quadratus lumborum, obliquus internus and tranſverſus abdominis, ſacrolumbalis and longiſſimus dorſi, ſerratus poſticus inferior, the diaphragm, the pſoæ major and minor.

The bodies of the vertebræ conſiſt almoſt entirely of ſpongy texture; it is covered by a very thin layer of compact bone: hence a vertebra, when thoroughly cleaned, is very light in compariſon to its bulk. In the recent ſtate it appears bloody and medullary. The circumference of the two ſurfaces is ſmooth, the centre rougher. At the ſame time that the cellular ſtructure of the vertebral bodies increaſes the ſtrength of the column, without adding to its weight, it makes theſe bones liable to thoſe affections which belong more particularly to ſuch ſtructure. The compact tiſſue is tolerably abundant in the atlas and axis; and it predominates conſiderably in the proceſſes, which, however, are cellular in their middle, and in parts where they are ſwelled, as at the ends of the ſpinous proceſſes in the loins, &c. The oſſification of the vertebræ goes on in three pieces; one for the body, and the two others for the lateral and poſterior parts: yet ſeparate points may be ſometimes ſeen at the baſes of the ſpinous proceſſes. The lateral portions are united to each other behind, at the baſis of the ſpinous proceſs; and they are united in front to the body, at the ſituation of the articular proceſſes. The atlas uſually has five primitive bony pieces; one for the anterior arch, two for the poſterior, and one for each ſide.

We have included the ſacrum and the os coccygis in the enumeration of pieces compoſing the ſpine, although they are generally denominated bones of the pelvis. Their deſcription may in truth be connected, without impropriety, either with that of the laſt mentioned cavity, or of the vertebral column. They belong, however, more naturally to the latter. The ſacrum is formed on the ſame model as the vertebræ, and conſiſts originally of five diſtinct pieces, juſt like vertebræ, united by fibro-cartilages; differing from vertebræ only in ſome inſignificant points of ſize, figure, &c. Theſe pieces are indeed ſoon conſolidated into one bone, which then has much leſs reſemblance to the vertebræ than it had before. One great office of the ſpinal column, that of continuing and protecting the medulla ſpinalis, belongs equally to the ſacrum. The modification which the ſpine exhibits in this part, ariſes from the attachment of the lower limbs: a large ſurface is neceſſary for this purpoſe, and a ſtrong bone; and theſe conditions are anſwered in the ſacrum, which in every other reſpect has the configuration belonging to the ſpine.

The *ſacrum* (os latum, clunium) is the largeſt bony piece of the vertebral column, placed immediately below the laſt lumbar vertebra, and at the back of the pelvis; ſupporting, above, the head, upper limbs, ſpine, and ſuperior part of the trunk, and tranſmitting the weight thus received from the laſt lumbar vertebra to the pelvis, where its broad ſides are ſtrongly tied to the oſſa innominata, between which it is received like a wedge; and containing the lower extremity of the medulla ſpinalis. Its baſis is joined to the laſt lumbar vertebra, in the ſame way as the individual vertebræ are connected to each other; its apex is united to the firſt bone of the coccyx. When viewed in its ſituation, it is not placed perpendicularly, but turned backwards, making an angle with the lumbar vertebræ, called the promontory.

The figure of the bone is wedge-ſhaped or triangular, with the baſis turned upwards, the apex downwards, and the two ſides placed laterally. It is ſymmetrical. It is not only broadeſt above, but alſo thickeſt from before backwards, and gradually diminiſhes downwards in both theſe directions. It is concave in front, and tolerably ſmooth, convex, and rugged behind. We ſhall deſcribe its ſpinal, pelvic, vertebral, and coccygeal ſurfaces, and the two lateral ſides.

The ſpinal ſurface is convex, very irregular, and covered by the origins of the muſcles, which fill the lateral hollows of the ſpinal column. We obſerve in it, 1ſt, on the middle line, four eminences, diminiſhing in ſize from above downwards, analogous to the ſpinous proceſſes of the vertebræ, of which they continue the ſeries, ſometimes running into a continuous bony ridge. Theſe are the ſpinous proceſſes of the ſacrum, affording points of attachment to muſcles. They are terminated below by a triangular opening, the end of the ſacral canal, which is cloſed by the poſterior ſacrococcygeal ligament, and bounded laterally by two prominent knobs, which are uſually articulated to two correſponding ones of the coccyx. Under theſe, ſometimes called the deſcending proceſſes of the ſacrum, the laſt ſacral nerve paſſes. The inferior opening of the ſacral canal is ſometimes much more extenſive, reaching nearly to the upper part of the bone, ſo that the canal is ſlit in its whole length: the opening in ſuch inſtances is ſtill occupied by ligament. 2dly. On each ſide, a rough depreſſion above, for the inſertion of powerful ligaments, which tie the ſacrum to the os innominatum; and, lower, four poſterior ſacral foramina, ſituated in a channel continuous with that of the vertebræ, but ſhallower, and filled by the lumbar muſcles. Theſe holes, diminiſhing in diameter from above downwards, are traverſed by the poſterior branches of the ſacral nerves, and communicate with the canal of the bone: they are bounded externally by more or leſs diſtinct prominences, which may be conſidered as repreſenting the tranſverſe proceſſes of the vertebræ.

The pelvic ſurface is concave, and correſponds more particularly to the rectum. It preſents, 1ſt, on the middle line, four ſlight tranſverſe ridges, indicating the points of union between the original pieces of the bone, and ſeparated by quadrilateral ſurfaces, a little concave, which anſwer to the anterior part of the bodies of the vertebræ; 2dly, on each ſide, the four anterior ſacral foramina, much larger than the poſterior, oppoſite to which they are placed, and with which they communicate by the ſacral canal, diminiſhing in ſize from above downwards, giving paſſage to the anterior branches of the ſacral nerves, and ſeparated by bony intervals, uniting in a ſurface, to which the pyramidalis is attached.

The vertebral ſurface, repreſenting the baſe of the triangle, exhibits a configuration very ſimilar to that of the ſurface of a vertebra, and is adapted for union with the laſt lumbar vertebra. On the middle and anterior part there is an oval ſmooth ſurface, cut rather obliquely, to correſpond to the oblique inferior ſurface of the laſt-mentioned bone, with which it is joined by means of a fibro-cartilage, at an angle, which forms the promontory of the pelvis. Immediately behind this is ſeen the orifice of the ſacral canal, which has a flattened triangular figure, with the baſis turned forwards, and the apex towards the ſpinous proceſſes; diminiſhes in ſize from above downwards; is continuous with the vertebral canal, from which it receives the lower end of the medulla ſpinalis, ſurrounded by its membranes; communicates externally by the anterior and poſterior holes juſt deſcribed, and terminates below at the triangular fiſſure already noticed. On each ſide of this round articulating portion the ſacrum forms, in front, a ſmooth, convex, tranſverſe ſurface, continuous with the iliac foſſa, and covered by ligaments. Behind, there are two concave articular proceſſes, facing backwards and inwards, and joined to the inferior articular proceſſes of the laſt lumbar vertebra. This proceſs is bounded in front by a ſlight notch, contributing to the opening for the paſſage of the laſt lumbar nerve; and behind by a thin edge, forming the lateral boundary of the ſacral canal, correſponding to the margin of the vertebral laminæ, and having the laſt of the yellow ligaments attached to it.

The coccygeal ſurface, repreſenting the baſe of the triangle, is very ſmall, and forms an oval face articulated to the coccyx.

The edges of the ſacrum are formed into broad ſurfaces, for articulation with the oſſa innominata. In theſe parts, which repreſent the tranſverſe proceſſes of the vertebræ, the reſemblance between them and the former bone is the leaſt. Each edge exhibits, above, a ſurface above two inches long, and an inch and a half broad, united with the os innominatum by the ſacro-iliac ſymphyſis, oblique in its direction, in conſequence of the wedge-like figure of the bone, and gradually decreaſing in breadth from above downwards, as the whole ſacrum diminiſhes in thickneſs in the ſame direction. This articular ſurface is divided by a waving line from above downwards, into the anterior and poſterior part: the former is comparatively ſmooth, and united by the intervention of a cruſt of cartilage to the os innominatum; the poſterior is ſcabrous and irregularly excavated, to afford attachment to powerful ligaments paſſing between the two bones.

The coccygeal extremity, or the apex of the triangle, is an oval ſurface for articulation with the firſt bone of the coccyx.

The bony ſubſtance of the ſacrum is like that of the vertebræ, cellular internally, and covered on the outſide with a compact layer. It is more denſe in the ſpinous proceſſes.

The multifidus ſpinæ, the longiſſimus dorſi and ſacrolumbalis, gluteus maximus, pyriformis, ſerratus poſticus inferior, latiſſimus dorſi, and obliquus internus abdominis, are connected to the ſacrum.

This bone is compoſed originally of five pieces, exactly reſembling vertebræ, joined together by fibro-cartilages, which remain till the fourteenth year, or longer, after which the ſeparate portions are conſolidated into one bone. Hence the ſacrum and os coccygis have been called the column of falſe vertebræ. Each of the ſacral vertebræ poſſeſſes in the fœtus certain diſtinct bony nuclei, like thoſe of the true vertebræ. There are five in each of the three upper ones, and three in each of the two lower. The lateral portions are conſolidated firſt; the anterior and poſterior parts later. The cartilages of the front diviſions do not entirely diſappear till the time of puberty, or even afterwards.

The ſacrum ſometimes conſiſts of ſix portions; very ſeldom of four.

The *coccyx* (os, or more properly oſſa, coccygis) is a triangular ſymmetrical bone, conſiſting of four pieces, which are united by cartilaginous ligaments in ſuch a way as to form a continuation of the curvature of the ſacrum, placed at the poſterior and inferior part of the pelvis, where it ſupports the termination of the rectum. The firſt piece is the largeſt, and they decreaſe ſucceſſively, but not always ſo: their breadth exceeds their length: they are joined by articular ſurfaces. The ſpinal face of the bone is convex, uneven, and marked by prominences, which indicate the original diviſions. The great ſacro-ſciatic ligament, and the gluteus maximus, are attached to it. To the pelvic ſurface, which is gently concave, marked by tranſverſe ridges, and covered by a thick ligamentous ſtratum, the rectum correſponds. The ſacral ſurface is the broadeſt and thickeſt part of the bone: it has an oval concavity articulated to the ſacrum, and behind that two aſcending tubercles, which join the two deſcending ones of the ſacrum, and form together the openings through which the laſt ſacral nerves paſs out. The edges are uneven, and occupied by the attachment of the leſs ſacro-ſciatic ligament: they unite below in a rounded angle, to which the levator ani is connected.

While the bones are ſeparate, the firſt is the largeſt: it is triangular, convex behind, and concave in front; the ſecond, third, and fourth, are circular and flattened.

The gluteus maximus, the curvator coccygis, the coccygeus, the levator ani, and ſphincter ani, are inſerted in this bone.

The bony ſubſtance of the coccyx is ſpongy, and remarkably looſe and ſoft in its texture. In the fœtus the four pieces are completely cartilaginous, and the oſſification takes place later than in the ſacrum. Late in life the different portions frequently anchyloſe; and ſometimes the bone itſelf is anchyloſed to the ſacrum: the latter event is leſs frequent in the female.

Articulations of the Vertebral Column.—From the great number of pieces which enter into its compoſition, the joints of the ſpine muſt neceſſarily be numerous. Moveable articulations are required, on account of the motions executed by various parts of the ſpine; but ſolidity and ſtrength are alſo neceſſary, becauſe the ſpine is the point of ſupport of the limbs and head, the centre from which their motions proceed, and becauſe it contains the ſpinal marrow, to which any injury, preſſure, or ſhock, would be ſo very dangerous. Hence we find the vertebræ joined by very broad ſurfaces, and otherwiſe very ſtrongly tied together, ſo that luxation is impoſſible, and the ſpine poſſeſſes as much ſtrength, as if it were compoſed of a ſingle piece, although a power of motion is combined with that capacity for reſiſtance. The numerous joints, and the great quantity of ſoft elaſtic matter in the ſpine, give a ſpring to all the motions of the trunk, and ſtop the effect of all ſhocks, ſo as to prevent their propagation, and to obviate concuſſion of important organs, particularly of the brain. But, beſides the articulations which join the component pieces of the ſpine, there are ſeveral others, by which various parts are joined to the ſpine. Such are the joints of the head with the firſt and ſecond vertebræ of the neck, and of theſe vertebræ with each other: theſe, and the motions they execute, are conſidered under the article HEAD. The connection of the ribs with the dorſal vertebræ is deſcribed under LUNGS. The articulation of the ſacrum with the oſſa innominata, and with the coccyx, and of the different pieces of the coccyx with each other, are deſcribed under PELVIS.

Articulations of the Vertebræ.—Theſe bones are joined, 1ſt, by their bodies; 2dly, by their articular proceſſes; 3dly, by their laminæ; and 4thly, by the ſpinous proceſſes. The mode of connection is the ſame throughout the ſpine, excepting in the caſe of the atlas and the axis. Of the uniting media, however, ſome form ſeparate and inſulated organs at each intervertebral interval; ſuch are the fibro-cartilages, and the yellow ligaments: others conſtitute common organs, embracing at the ſame time the whole vertebral column, or its greateſt part, as the anterior and poſterior vertebral and the ſupraſpinal ligaments. Yet the fibres of the latter do not run through the whole length.

The bodies of the vertebræ are united by an anterior and a poſterior vertebral ligament, and by a fibro-cartilage between every two bones.

The anterior vertebral ligament, or faſcia longitudinalis anterior, occupies the anterior ſurface of the column, extending from the axis to the upper part of the ſacrum. It is not equally ſtrong nor broad throughout: it is narrow in the neck, broader in the back, and ſtill wider in the loins. In the firſt ſituation it is thin, ſtronger in the ſecond, and again rather thin in the loins, where the tendons of the crura diaphragmatis are intermixed with it. The fibres of this ligament do not run through the whole length of the column; ſome end and others begin in each bone. This ligament conſiſts of a thin ſtratum cloſely adhering to the bone, and covered, in the neck, by the pharynx and œſophagus, in the back, by the latter, by the aorta, vena azygos, and thoracic duct, and in the loins by the aorta and the inferior vena cava. At the ſides it correſponds, in the neck, to the recti majores antici and longi colli; in the loins to the pſoæ. It adheres to the fibro-cartilages, and to the projecting edges of the vertebral bodies, more cloſely than to the concavities of the latter. The more ſuperficial fibres go from one vertebral body or fibro-cartilage to the fourth or fifth below; others belong to three bones or fibro-cartilages; and the deepeſt only to two. The fibres are interwoven with thoſe on the front of the fibro-cartilages; and they leave ſmall intervals for the paſſage of veſſels. At the ſides of this ligament in the neck, under the longi colli, are two ſmall fibrous faſciculi for each vertebra, paſſing obliquely downwards and outwards from the vertebra above to that next below it.

The poſterior ligament (faſcia longitudinalis poſtica) occupies the poſterior aſpect of the vertebral bodies, where they form the front of the canal, extending from the axis and the occipito-axoid ligament, or apparatus colli ligamentoſus, to the ſacrum. It is more denſe in its ſtructure than the anterior, and appears more diſtinct, ſmooth, and ſhining. The narroweſt part of it is in the back: it enlarges at the fibro-cartilages, and is contracted at the bodies of the vertebræ; thus, when viewed in its whole length, it is alternately contracted and expanded at each vertebra and its neighbouring cartilage. The dura mater covers it behind, ſeparated from it by a looſe cellular tiſſue, never containing fat, but often much ſerous fluid. It correſponds in front to the fibro-cartilages and the bodies of the vertebræ, adhering leſs cloſely to the latter than to the former. Like the anterior ligament, it conſiſts of ſuperficial and deep-ſeated fibres, of which the former are the longeſt, and paſs over three or four vertebræ, while the latter go from one bone or fibro-cartilage to the next.

The fibro-cartilages (ligamenta intervertebralia) are organs, of which the nature is little underſtood, holding the middle place, in point of ſtructure, between ligament and cartilage, and occupying the intervals of the vertebral bodies throughout the column, excepting between the atlas and axis. Their form varies according to that of the bodies which they unite; and conſequently is different in the neck, back, and loins. Their thickneſs increaſes ſucceſſively from above downwards; ſo that the lumbar are ſeparated by larger intervals than the cervical and dorſal vertebræ. Moreover, they are thicker in front than behind, in the neck: on the contrary, they are thickeſt behind in the back; and the arrangement in the loins is the ſame as in the neck: theſe differences are obviouſly connected with the natural bendings of the column. The fibro-cartilages adhere very intimately above and below to the correſponding flat ſurfaces of the vertebræ. In the fœtus they adhere to the cartilages of oſſification; when they are removed nothing remains attached to the vertebræ; but, in the adult, the bony fibres and thoſe of the fibro-cartilages are ſo completely identified, that we find no inſtances in the animal economy of ſtronger union. The circumference of theſe ſubſtances correſponds to the anterior and poſterior vertebral ligaments: on each ſide, they form part of the holes through which the ſpinal nerves paſs; and in the back they contribute to the articular cavities for the heads of the ribs.

The fibro-cartilages are formed externally of concentric fibrous laminæ, numerous in front and at the ſides, fewer behind, with decuſſating fibres, ſeparated by more conſiderable intervals as we approach the centre. In the latter we find a ſoft pulpy tiſſue, increaſing in quantity as the intervals increaſe in breadth. The fibrous laminæ degenerate gradually into the pulpy ſtructure, which occupies alone the middle of each fibro-cartilage. This tiſſue is moſt abundant in the child, where it is alſo ſoft, whitiſh, and even nearly tranſparent, while it is yellowiſh and thick in the adult. It becomes denſe and compact in the old ſubject, and is conſtantly diminiſhing. To it the fibro-cartilages owe their pliancy and elaſticity; while their ſtrength reſides in the laminæ, which incloſe this ſoft ſtructure. Hence the ſpine is diſtinguiſhed by the firſt property in infancy; while the other predominates afterwards. The laminæ ſoon become red when immerſed in water: the middle part ſwells and riſes into a conical projection. If the ſpine be ſawn through longitudinally, the fibro-cartilage ſwells out, on the cut ſurface, beyond the bone. The effect of theſe ſubſtances in reſtoring the column, when it has been bent in any direction, is very obvious. The inflexion compreſſes the fibro-cartilages at the bent part; and they reſtore themſelves as ſoon as the compreſſing cauſe ceaſes to act. When the body has been long erect, the fibro-cartilages yield to the weight which preſſes them from above, and thus the length of the ſpine, and conſequently of the body, is diminiſhed: the ceſſation of this preſſure, when the body is in the horizontal poſition, allows them to recover their original dimenſions. See CARTILAGE.

The correſponding faces of the articular proceſſes are covered by thin cartilaginous layers, and furniſhed with a ſmall ſynovial membrane, which is very cloſely drawn between the oppoſed ſurfaces, and contains very little ſynovia. Several ſhort and irregular, but ſtrong ligamentous fibres, lie on this membrane.

The yellow ligaments (lig. ſubflava), ſo called from their colour, tie together the laminæ of the vertebræ, which do not touch each other, and complete the canal of the ſpine, which would be otherwiſe open at the intervals of their laminæ. The firſt of theſe ligaments is placed between the ſecond and third cervical vertebræ; the laſt between the fifth lumbar and the ſacrum. Each conſiſts of two portions, a right and left, united at an angle towards the baſis of the ſpinous proceſs, and having at this union a ſmall interval containing a little cellular tiſſue. Each portion is attached, above, to the inner ſurface of the ſuperior lamina; and below to the upper edge of the inferior: hence they are hidden behind, and can only be ſeen to advantage from the vertebral canal; they may be beſt expoſed by ſawing out the ſpinous proceſſes, and their laminæ, from the vertebral column, in one continuous piece. They correſpond, in front, to the dura mater, to which they are connected by a looſe cellular tiſſue; behind, to the inner ſurface of the upper laminæ of each interval, and to the multifidus ſpinæ. The angle formed by the union of the two lateral pieces is continuous in the back and loins with the interſpinal ligaments: on the outſide each is contiguous to the ſynovial membrane of the articular proceſſes. Their fibres are numerous and cloſely ſet; longer towards the canal, where they appear ſmooth and poliſhed, than towards the vertebral channel, where they are rough and uneven. There is very little cellular tiſſue in their compoſition, ſo that they are diſſolved under ebullition with great difficulty, and reſiſt it longer than any analogous organs. They are elaſtic, very ſtrong, ſo that vaſt force is required to break them: ſtronger indeed than the fibro-cartilages, in which the fibres are ſeparated by much of the pulpy texture. It is very clear that theſe ligaments will powerfully tend to reſtore the ſpine, after it has been inclined forwards.

The ſpinous proceſſes, ſeparated by intervals more or leſs conſiderable in different ſituations, are united by two kinds of ligaments; one of which connects the proceſſes themſelves, while the other envelopes their points.

The interſpinal ligaments (membrana interſpinalis) occupy the intervals of the proceſſes, but do not exiſt in the neck, where the correſponding ſpaces are filled by the interſpinales muſcles. Their breadth and ſtrength increaſe from above downwards; in the back they are narrow, elongated, and thin, and can ſcarcely be ſaid to exiſt in the upper part of the region. They are quadrilateral, broader and thicker in the loins, where they may offer conſiderable reſiſtance to the ſeparation of the proceſſes. Their points of attachment are the lower edge of one ſpinous proceſs, and the upper edge of the next: they correſpond, in front, to the angle of union of the two portions of the yellow ligaments; behind, to the ſupraſpinal ligaments; and on the ſides, to the multifidus ſpinæ and longiſſimus dorſi. They are compoſed of decuſſating fibres.

The ſupraſpinal ligament (lig. quo apices vertebrarum connectuntur) extends along the points of the ſpinous proceſſes of the back and loins, from the ſeventh cervical vertebra to the ſpinous proceſſes of the ſacrum. It is very thick in the loins, where it is ſo interwoven with the tendinous attachments of the muſcles, that they can hardly be diſtinguiſhed. In the back it is thinner and more diſtinct from the aponeuroſis. The longitudinal direction of its fibres ſerves to diſtinguiſh it from the tendons, of which the fibres are oblique. Its fibres are of different lengths; the deepeſt go from bone to bone; the more ſuperficial are longer, paſſing over one, two, or more vertebræ, and giving origin to the aponeurotic fibres of the neighbouring muſcles. The ſkin covers this ligament behind; adhering to it by a cloſe cellular tiſſue.

The ligamentum nuchæ, which ariſes from the cervical ſpinous proceſſes, belongs more to the head than to the ſpine. It is deſcribed under HEAD.

The laſt vertebra of the loins is articulated to the ſacrum, juſt in the ſame way as the individual vertebræ are joined together; *viz.* by a fibro-cartilage, by yellow ligaments, by an interſpinal ligament, and by articular proceſſes.

The Spine conſidered as a Whole.—The twenty-nine bones juſt deſcribed, *viz.* the twenty-four vertebræ, the ſacrum, and the four oſſa coccygis, are joined by the articulations which have been now explained, (all being connected by the intervention of fibro-cartilages, except the atlas,) ſo as to form, by their aſſemblage, the ſtrong but flexible bony column which ſuſtains the head, forms the baſis of the trunk, affords a point of attachment to the upper limbs, and below is received between and ſupported by the haunch bones. We diſtinguiſh in it an anterior, a poſterior, and two lateral regions, and two extremities. We may obſerve, in general, that the whole column increaſes in ſize from above downwards, as it has to ſupport an increaſing weight; but to this there are ſome exceptions, that will be noticed.

The anterior region, compoſed of the bodies of the vertebræ and the intermediate fibro-cartilages, preſents in ſome degree the appearance of a bony pillar, which term is little applicable to the rows of bony proceſſes, which form the lateral and poſterior aſpects of the ſpine. This region is broad in the neck, narrow in the back, and again ſpreads out in the loins. Its breadth in the firſt ſituation ariſes from the ſmallneſs and inconſiderable prominence of the vertebral bodies; in conſequence of which the tranſverſe proceſſes in this region form part of the anterior aſpect of the ſpine; while in the back and loins, the bodies form, by their bold convex projection, the whole front of the column. The front of the ſpine preſents a ſeries of ſuperficial tranſverſe excavations, and of prominent edges which bound them: the number of the latter is double that of the former, as each tranſverſe channel is bounded above and below by a ridge. Theſe excavations are confined to the front in the neck; but they reach to the ſides in the middle of the column. The anterior vertebral ligament, the recti capitis majores, the longi colli, the vena azygos, thoracic duct, aorta, and inferior vena cava, cover the ſpine in front.

We obſerve, on the poſterior aſpect, in the middle line, the ſeries of ſpinous proceſſes, projecting horizontally at the upper and lower parts, and very ſlanting in the middle. They are ſeparated by intervals, which are large in the neck and ſtill more ſo in the loins; but very much narrowed in the back, in the middle of which the proceſſes actually overlap. In the neck and loins there are openings between the laminæ, leading into the vertebral canal, in the ſkeleton; but the ſlanting of the ſpinous proceſſes covers theſe in the back. The points of the ſpinous proceſſes are generally all in the ſame line; but there may be deviations, ariſing either from a lateral inclination of the proceſs, or from an unnatural poſition of the vertebra. On each ſide of the ſpinous proceſſes there is a longitudinal hollow, beginning at the upper extremity of the column, and ending below upon the ſacrum. Theſe lateral hollows are broad above, contracted towards the middle, and narrow below. They are formed by the ſeries of vertebral laminæ, ſeparated by larger or ſmaller ſpaces, which are occupied by the yellow ligaments. They are filled by the vertebral muſcles, particularly by the multifidus ſpinæ.

The ſeries of tranſverſe proceſſes occupies each lateral region; but they have not all the ſame direction: they are more anterior in the neck and loins, and thrown backwards in the back. Between them in the neck, and in front of them in the back and loins, there is a ſucceſſion of large holes, increaſing in ſize from above downwards, and giving paſſage to the vertebral nerves. In front of theſe, in the back, are the ſurfaces for articulation of the heads of the ribs.

The ſuperior extremity, articulated to the occiput, forms a right angle with it on each ſide; and an anterior and poſterior angle, which vary according to the flexion or extenſion of the head. This extremity preſents, from before backwards, the anterior arc of the atlas, the tooth-like proceſs, the commencement of the canal, and the poſterior arc of the atlas. On each ſide of the canal, towards the front, there is the concavity for the occipital condyle, and the large tranſverſe proceſs. The inferior extremity preſents merely the ſmall rounded point formed by the laſt bone of the coccyx.

The length of the ſpine does not vary greatly in different individuals; the differences of ſtature depending more on the limbs than on this column. In malformations, however, where it is curved in various directions, the ſtature is much affected; and the limbs, although not exceeding their ordinary ſize, appear diſproportionately long. We have already obſerved, that the compreſſion of the fibro-cartilages by the weight which they naturally ſupport, diminiſhes the length of the ſpine after long ſtanding; and that the column recovers its former length by repoſe in the horizontal poſture. This effect is leſs ſtrongly marked in the old ſubject, where the fibro-cartilages are very denſe, and conſequently do not eaſily yield to preſſure.

The ſize of the column increaſing from above downwards, in proportion to the greater weight and more powerful effects it has to ſupport, it may be regarded as a pyramid, of which the baſis is below, and the apex above. Yet this augmentation is not gradual throughout; and the column may be conſidered as the aſſemblage of four pyramids. The upper end, including the atlas and axis, deſtined for articulation with the head, which it ſupports, is larger than the immediately ſucceeding part of the neck. From the third to the ſeventh cervical vertebra the ſpine is gradually expanded: thence, to the third or fourth dorſal vertebra, it contracts again; and is gradually augmented from the latter to the baſis of the ſacrum: it contracts again from the baſis of the ſacrum to the apex of the os coccygis. Meaſured tranſverſely, the ſpine increaſes from the third cervical to the fifth dorſal vertebra, while the remaining dorſal and the lumbar vertebræ are nearly of the ſame breadth, or increaſe very ſlightly downwards. The depth of the vertebræ is alſo increaſed; but the inferior cervical are all nearly of one depth.

The intervertebral intervals are nearly of uniform ſize, down to the third dorſal; from which they increaſe downwards. The flat ſurfaces of a vertebra are always parallel to each other, and the intervals are conſequently of the ſame depth before and behind. There is an exception, however, of the parts in which the column is bent; the intervals of the third, fourth, fifth, and ſixth dorſal vertebræ being narroweſt in front, while thoſe between the fourth and fifth lumbar, and the ſacrum, are broadeſt in front.

The ſpinal column is ſtraight, when viewed before or behind; and might be divided by a perpendicular line into a right and left correſponding half: but, when we view it laterally, we find that it is bent in ſeveral parts, ſo as to deſcribe a waving line, in which each anterior prominence is accompanied by a correſponding poſterior convexity. The cervical portion projects ſlightly in front; the dorſal is decidedly convex behind. The concavity of the dorſal part of the ſpine combines with the inclination backwards of the tranſverſe proceſſes to increaſe the capacity of the thorax. The greateſt depth of this concavity is oppoſite to the lower bone of the ſternum. In the loins, the ſpine is again convex in front, while the ſacrum and coccyx ſlant backwards remarkably, ſo as to preſent a deep concavity. The middle of the firſt convexity correſponds to the fourth cervical vertebra; that of the ſucceeding concavity to the ſeventh or eighth dorſal; the middle of the lumbar projection to the junction of the fifth lumbar vertebra with the ſacrum; and that of the ſacral concavity to the middle of the bone. About the third, fourth, and fifth dorſal vertebræ, the ſpine is ſometimes a little convex towards the right. This has been aſcribed to the preſence of the aorta; but that cauſe is manifeſtly inadequate. The explanation, which is grounded on the greater uſe of the right arm, and a conſequent inclination of the trunk to the left ſide, in order to afford a firmer point of ſupport, appears rather more probable. Any habitual attitude, particularly when perſiſted in from childhood, will affect the direction of the vertebral column. Under various diſeaſed ſtates, remarkable curvatures are produced; in which we find that the vertebræ and their fibro-cartilages become accommodated to the unnatural poſition, being greatly diminiſhed in depth on the concavity of the curve, ſo that the two ſurfaces are no longer parallel. It is alſo conſtant, that a bend in one part renders curvature neceſſary in another, in order to preſerve the centre of gravity in a ſtraight line. The poſition of the head and upper limbs is alſo calculated to maintain the equilibrium of the body; and thus nearly the whole frame is influenced by a cauſe originally affecting only a part of the ſpine.

The canal of the ſpine extends throughout the column, excepting a ſmall portion of the lower end of the ſacrum and the os coccygis: it is continuous, above, with the cavity of the cranium, and ends below on the back of the ſacrum. It does not occupy the centre of the column, being placed much nearer to the poſterior part. In the neck it is large; more ample in the upper than in the lower part of the back, the narroweſt part being from the ſixth to the ninth: it expands a little in the eleventh and twelfth dorſal vertebræ, is very large in the lumbar, and again ſuddenly contracted in the ſacrum. Its figure is triangular, with the angles rounded; ſo that it has an anterior, and a right and left ſurface; it is more nearly round in the middle, and quite triangular in the ſacrum. It partakes of all the curvatures of the ſpine. It is formed in front of the backs of the vertebral bodies and fibro-cartilages, covered by the poſterior ligaments. Behind, the laminæ and the yellow ligaments compoſe it. On each ſide it preſents a ſeries of twenty-nine large foramina for the paſſage of the nerves; or there are thirty, if we include the exit of the firſt cervical pair, between the occiput and the atlas.

This canal is lined by a prolongation of the dura mater, including the medulla ſpinalis, covered by its arachnoid coat and pia mater. (See Brain and Nervous *Syſtem.*) The dura mater is ſurrounded by a looſe cellular tiſſue, containing ſerous fluid.

Developement of the Spine.—Few parts of the ſkeleton undergo more remarkable changes in the progreſs of oſſification than the vertebral column. It differs much in the child and the adult; and in old age is again very different from both.

It is one of the firſt parts formed in the embryo, where it ſeems to be a kind of foundation, on which the ſtructure of the body is erected. Its form is diſcernible at the end of the third week after conception, when we can juſt ſee the head and a curved line connected to it. Long before the extremities can be ſeen, the ſpine continues viſible. The commencement of its oſſification by numerous points may be dated about the end of the ſecond month. The gelatinous ſpine, or carina, as it has been called from its incurvated keel-like ſhape, is the firſt trace of developement in the incubated egg.

The formation of the ſpine is more advanced, and its ſize more conſiderable, in compariſon with other parts, particularly with the pelvis and lower limbs, at the time of birth. Hence the trunk is proportionably longer. The general ſtature too, at this time, depends on the ſpine, while in the adult it is influenced more by the lower limbs. This great length of the ſpine correſponds to the depth of the cranium, which is much more conſiderable proportionally in the fœtus and young ſubjects than in the adult. The vertebral canal being alſo large, the breadth of the column, which depends much on the ſize of the canal, is conſiderable. All parts which relate to this excavation are much advanced. On the contrary, whatever has reference to ſupport or locomotion, is little developed at this time. The ſpinous proceſſes do not exiſt; conſequently the points of attachment for the muſcles are weaker. The bodies are ſtill in great meaſure cartilaginous: behind, where they contribute to the canal, they are the moſt formed; but there is much ſoft ſubſtance in front, where, when the ſpine is dried, we ſee merely a ſeries of rounded bony tubercles. Such a ſtate is very unfavourable to the ſolid ſupport which is neceſſary for preſerving the erect attitude. At this age, the tranſverſe proceſſes are ſmall in the loins, where they relate to the muſcles only; they are much more conſiderable in the back and neck, on account of their connection with the ribs and the vertebral artery.

The column, at this time, does not form a pyramid, of which the baſis is downwards and the apex upwards. The cervical portion is larger than the lumbar, on account of the developement of the tranſverſe proceſſes, which, being placed nearly on the ſame line with the bodies, give to the former region a conſiderable volume; and of the comparatively imperfect ſtate of the lumbar vertebræ. The dorſal and lumbar regions are nearly equal in ſize; but in ſome inſtances the former vertebræ are largeſt. As the principal effort, in ſtanding, is ſupported by the loins, the imperfect ſtate of the lumbar vertebræ is very unfavourable to the maintenance of that attitude in the newly born child. The imperfectly developed ſtate of the bones coincides with the inconſiderable volume of the pelvis.

The direction of the column is remarkable in the fœtus: it is ſtraight, or at leaſt exhibits the hardly ſenſible commencement of thoſe curves, which it will preſent in the ſequel. In conſequence of this ſtraightneſs, the vacillations which occur in the erect poſture of the body, and in all the motions executed in that poſture, are much more ſenſible, and the centre of gravity is more eaſily carried beyond the baſis of ſupport. Hence another reaſon why newly born children cannot keep themſelves upright, or move in that attitude.

The vertebral column, in early age, is ſmall and narrow in front, particularly at the back and loins. In conſequence of the want of ſpinous proceſſes, there is great flexibility, particularly backwards. The latter property is favoured by the large quantity of ſoft ſubſtance in the column; the cartilaginous portion of the vertebral bodies being added to the fibro-cartilages. The vertebral channels are very ſhallow, in conſequence of the ſtate of the ſpinous proceſſes. The lateral holes are very large: the laſt lumbar vertebra does not form ſo marked an angle with the ſacrum. The upper end of the column does not differ materially from its ſtate in the adult.

As oſſification proceeds, all the peculiarities juſt enumerated gradually diſappear. The erect attitude is more ſecure, and progreſſion is performed with greater facility. Hence the ſupport of the trunk by all the limbs, is a reſult of the organization of the fœtus. The child, having crawled about for ſome time, gradually experiences thoſe developements of its bony and muſcular fabric, which enable it to appear in the erect poſture as a biped. The vertebral column, however, arrives at the ſtate which we have deſcribed as exiſting in the adult, by a very ſlow progreſſion. At the time of puberty, in both ſexes, the atlas and the coccyx are complete. In the ſix lower cervical vertebræ, the proceſſes are not yet conſolidated to the body; and the vertebræ of the back and loins are ſtill leſs complete, having a bony plate at each ſurface of the body, and a bony nucleus in the ſpinous proceſs. Slight marks of the original ſeparation are ſtill viſible in the ſacrum. In a few years theſe imperfections diſappear; the apices of the ſpinous proceſſes of the back and loins being among the laſt parts that are conſolidated.

In the old ſubject, the intervertebral fibro-cartilages ſhrink and become harder: ſometimes, but very rarely, they oſſify. The ſpine, at this age, generally bends forwards, apparently from debility of the poſterior muſcles: thus, the force which ſhould counterbalance that tendency to fall forwards, ariſing from the poſition of the viſcera in front of the ſpine, is gradually loſt. To counteract this inclination of the ſpine forwards, and ſupport the centre of gravity, the pelvis recedes, and the knees and legs project in front. The latter circumſtance is more ſtrongly marked in proportion as the inclination of the ſpine forwards is more conſiderable. The weight of the trunk being carried towards the front, the baſe of ſupport muſt move forwards alſo. There is always an exact proportion between the bending of the ſpine, the receding of the pelvis, and the advance of the knees. In this caſe, the trunk and lower limbs together exhibit the ſame phenomenon as the ſpine itſelf in its particular curves, which balance each other in the neck, back, and loins.

Mechaniſm of the Spine.—This muſt be conſidered in three points of view: 1ſt, with reference to the canal; 2dly, as the point of ſupport of the trunk; and 3dly, as the centre of the motions performed by the latter.

1. *Of the Canal.*—All the arrangements about the vertebral column are calculated to enſure the ſafety of this part. The breadth of the vertebral bodies; the multiplicity and ſtrength of the uniting ligaments; the parts lying in front of the ſpine in the neck, cheſt, and abdomen; and the thick muſcular maſſes that fill the vertebral hollows behind; all concur in protecting the contents of the canal from external injury. Hence the reſiſtance which the ſpine oppoſes to all efforts directed againſt it; a reſiſtance which renders luxation impoſſible. The individual vertebræ are capable of ſo very ſlight a motion, that the medulla ſpinalis cannot be compreſſed in any inflexions of the ſpine.

2. *Mechaniſm of the Spine in Standing.*—Here the ſpine is the point of ſupport of the trunk, of which it tranſmits all the weight, together with that of the head, to the pelvis.

The mode in which the head is ſupported on the ſpine, is conſidered under the article Head. The part in front of the articulation certainly preponderates over that behind;

but the difference is leſs conſiderable, than it would appear from noticing merely the relation of the occipital condyles to the front and back of the head, in conſequence of the anterior portion containing the face, of which the weight does not correſpond to the bulk, while all the poſterior part is ſolid and heavy.

If the poſition of the head tends to incline the ſpine forwards, the ſame effect is much more ſtrongly produced by the ſituation of the pectoral and abdominal viſcera wholly in front, without any thing to counterbalance them behind. The muſcles of the vertebral channels, inſerted either in the ribs or the vertebræ, exert a conſtant effort in oppoſition to that of the anterior viſcera, maintaining by their exertion the vertebral column, and, conſequently, the trunk, in the erect attitude. The greateſt effort is below, where the ſpine ſupports the moſt conſiderable weight. Here the muſcles are thicker, the bones large, and their proceſſes more prominent. Here, too, the ſenſe of fatigue is felt after long ſtanding; whence ariſes the practice of tying a firm band round the loins, to ſupport the muſcles and favour their action.

Thus, in ſtanding, the ſpine is placed between two forces acting in oppoſite directions; an anterior paſſive one, which is the trunk; a poſterior active one, the action of the extenſor muſcles. The habitual tendency of the ſpine to bend forwards, produced by the weight of the viſcera, is further obviated by the hip-joints, at which the trunk is ſuſtained on the lower limbs, being placed in front of the ſacro-iliac ſymphyſes. The baſis of the trunk occupies the ſpace between the latter ſymphyſes and the cotyloid cavities. It will be readily underſtood that falls muſt have been much more frequent, if the thighs had been articulated on the ſame line with the ſacrum. The waving line deſcribed by the vertebral column, and allowing extenſive motion in the upper parts, without the line of gravity, which paſſes through all the curves, abandoning the baſe of ſupport, is another diſpoſition very favourable to the ſolidity of the trunk in its erect attitude. The gradual increaſe in ſize of the column, from above downwards, contributes to the ſame end. Thus, ſtanding cannot be regarded, by any means, as an attitude of repoſe; it requires great efforts, which naturally cauſe conſiderable laſſitude, if the poſture be long maintained.

3. *Motions of the Spine.*—The general motions are, forwards, backwards, to either ſide, or in the intermediate directions. Inclination forwards, or flexion, as it is commonly termed, is the moſt extenſive, as all our principal efforts have this direction. In this motion, the anterior vertebral ligament is relaxed; the fibro-cartilages are looſened in front, and ſtretched behind; the poſterior vertebral ligament, the yellow ligaments, and thoſe of the ſpinous proceſſes, are ſtretched. The laminæ of the fibro-cartilages, being much more numerous in front than behind, yield more readily to motion in the former than in the latter direction. In extenſion, we obſerve phenomena exactly contrary to theſe. The muſcles, however, which produce extenſion, being fixed to the vertebral proceſſes, are very near the centre of motion, and, conſequently, act leſs powerfully than the flexors, which operate through the medium of the ribs, and, conſequently, at a diſtance from the centre of motion. The ſpinous proceſſes, too, particularly of the back, limit extenſion very much.

In inclination to either ſide, the fibro-cartilages are principally affected; being ſtretched on one ſide and relaxed on the other. The ribs principally limit this motion, by coming in contact with each other.

All theſe motions are much more ſenſible at the junction of the dorſal and lumbar regions than elſewhere. When they are all performed in ſucceſſion, the trunk is carried round in a circular direction, deſcribing a cone, of which the baſis is upwards, the apex downwards.

Beſides the motions juſt enumerated, a power of rotation has been aſcribed to the ſpine, in which the vertebræ are ſuppoſed to be twiſted on their axes. Winſlow admits this, and Bichat does the ſame; adding, however, that it can only be accompliſhed with conſiderable difficulty. He calls it a ſpecies of general twiſting, in which all the ligaments are ſtretched, reſulting from the partial twiſting of each fibro-cartilage. When we conſider how the vertebræ are joined together; when we reflect on the nature of the fibro-cartilages, on the yellow ligaments, on the mechanical locking of the articular proceſſes, and more particularly on the attachments of the ribs, and the overlapping ſpines in the back, we ſhall begin to doubt whether this rotation be poſſible. Dr. Barclay decidedly denies it. (Muſcular Motions, p. 337, et ſeq.) If the head and ſhoulders be prevented from moving on the trunk, and the pelvis be alſo kept motionleſs, no rotation of the ſpine can be effected. An appearance takes place, which might be aſcribed to ſuch a rotation, from a motion of the pelvis on the hips. This may eaſily be detected, by placing a rod of ſome feet in length acroſs the pelvis, when any motion of the latter will be immediately viſible at its extremity.

The motions vary in each region: on account of the ſmallneſs of the vertebræ, the obliquity of the articular proceſſes, the ſhortneſs and horizontal projection of the ſpinous proceſſes, which are not tied together by interſpinal ligaments, the quantity of motion in all the directions already enumerated is conſiderable. The cervical region either repreſents a ſimple lever, or it may be conſidered, in connection with the head, as an angular lever, and will follow all the motions of that part. In one part of this region there is a true rotatory motion; it is at the articulation of the atlas with the axis. Whenever the head is twiſted to one ſide or the other, there is a revolution of the former bone on the latter, and not any general twiſting of the ſpine.

Every thing concurs to limit motion in the back: for example, the articulations of the ribs to the bodies and tranſverſe proceſſes, and their connection to the ſternum in front; the length and overlapping of the ſpinous proceſſes.

In the loins, again, there is free motion; particularly above, at the junction of this region with the back.

The motions of the individual vertebræ are extremely obſcure; but they take place in the ſame direction as the general motion which we have juſt deſcribed. The viſible movement of any part of the ſpine reſults, therefore, from the combined effect of ſeveral hardly ſenſible motions: one vertebra could not move ſufficiently on another to produce a perceptible motion of the trunk. This circumſtance concurs with ſeveral others relating to the mode of union of the vertebræ, and the mechanical confinement of the articular proceſſes, to render luxation impoſſible: meaning by that term, a diſplacement of the bone without any fracture. The effort is diſtributed over a conſiderable region, and cannot therefore act ſufficiently on a ſingle bone. Neither can any force be eaſily applied before or behind, ſufficient to drive out one vertebra from its place. Moreover, were ſuch a force actually applied, the vertebra could not be diſplaced forwards without a fracture of its inferior, nor backwards, without that of its ſuperior articulating proceſſes.

Of the muſcles which are concerned in theſe motions, ſome act directly on the trunk, while others affect it through the medium of the ribs, the ſcapulæ, &c. All of them, being placed on the right or left ſide of the body, muſt have the power of moving the trunk laterally, more or leſs, according to their degree of obliquity, or their diſtance from the meſial plane. The following is a liſt of the muſcles which carry it forwards; including both thoſe which act directly and the indirect ones.

Pectorales majores and minores; ſerrati magni; obliqui externi abdominis; obliqui interni abdominis; tranſverſi abdominis; recti abdominis; pyramidales; pſoæ magni and parvi.

The muſcles moving it backwards are, trapezii; rhomboidei; latiſſimi dorſi; ſerrati poſtici ſuperiores and inferiores; ſacrolumbales; longiſſimi dorſi; ſpinales dorſi; ſemiſpinales dorſi; multifidi ſpinæ; interſpinales; intertranſverſarii dorſi and lumborum; quadrati lumborum.

The muſcles of the neck may be arranged in like manner into the two claſſes of (1) thoſe which incline it forwards; and (2) thoſe which incline it backwards. In both claſſes, thoſe which are to the right or left of the meſial plane, will inflect the cervical column to their reſpective ſides. Theſe liſts include, beſides the muſcles which act immediately on the neck, thoſe which influence it through the head.

1. Muſcles bending the neck forwards: latiſſimi colli; biventres maxillæ; mylo-hyoidei; genio-hyoidei; genio-hyogloſſi; omo-hyoidei; ſterno-hyoidei; thyro-hyoidei; ſterno-maſtoidei; recti capitis interni majores and minores; recti capitis laterales; longi colli; ſcaleni antici.

2. Muſcles bending it backwards: trapezii; rhomboidei minores; ſerrati poſtici ſuperiores; ſplenii capitis and colli; complexi; trachelo-maſtoidei; cervicales deſcendentes; tranſverſales cervicis; ſpinales cervicis; ſemi-ſpinales cervicis; multifidi ſpinæ; recti capitis poſtici majores and minores; obliqui capitis ſuperiores and inferiores; ſcaleni poſtici; and levatores ſcapularum.

The ſcaleni medii and intertranſverſales can only inflect laterally.

Spine, *Diſeaſe and Curvature of*, in *Surgery*. In the preſent article we intend to conſider a particular diſeaſe of the ſpine, attended with a total or partial abolition of the power of uſing, and ſometimes even of moving, the lower extremities.

It was that eminent ſurgeon Mr. Pott, who gave the firſt accurate deſcription of this ſerious affliction. To this diſtemper, he obſerves, children are the moſt ſubject; adults are by no means exempt from it; but it hardly ever affects perſons after the age of forty. In infants, the true cauſe of the paralytic diſorders of the lower limbs is ſeldom diſcovered by parents or nurſes, who never imagine that it is ſituated in the back-bone. When the diſeaſe affects a child who has been able to walk, the loſs of the uſe of his legs is gradual, though not very ſlow. He at firſt complains of being very ſoon tired, and is unwilling to move about much; and very ſhortly afterwards he frequently trips and ſtumbles, although there be no impediment in his way. Whenever he attempts to move briſkly, he finds that his legs involuntarily croſs each other, by which he is frequently thrown down. Upon endeavouring to ſtand erect, even for a few minutes, his knees give way and bend forward.

When the diſtemper is a little farther advanced, it will be found that the patient cannot, without much difficulty and deliberation, direct either of his feet preciſely to any exact point; and very ſoon after this, both thighs and legs loſe a great deal of their natural ſenſibility, and become perfectly uſeleſs for all the purpoſes of locomotion. In adults, Mr. Pott obſerved, that the progreſs of the diſeaſe was rather quicker than in children.

The affection of the lower limbs is ſomewhat different from a common nervous palſy. The legs and thighs are rendered unfit for all the purpoſes of locomotion, and do alſo loſe much of their natural ſenſibility; but they have neither the flabby feel which a truly paralytic limb has, nor that ſeeming looſeneſs at the joints, nor that total incapacity of reſiſtance, which allows the latter to be twiſted in almoſt all directions. On the contrary, the joints are often very ſtiff, and the feet frequently cannot be placed flatly on the ground, in conſequence of the toes pointing downward.

The diſeaſe of the ſpine varies in ſituation, extent, and degree; being either in the neck, back, and ſometimes, though very ſeldom, in the upper part of the loins; ſometimes comprehending only two vertebræ, ſometimes three, or more.

Some patients are rendered totally incapable of walking at a very early period of the diſtemper; others can manage to move about with the help of crutches, or by graſping their own thighs with their hands.

When a weak infant is the ſubject, and the curvature reſulting from the morbid ſtate of the ſpine is in the vertebræ of the back, it is not unfrequently productive of deformity, by rendering the back humped, and by alterations which the poſition of the ribs and ſternum undergoes, in conſequence of the flexure and morbid ſtate of the ſpine.

The general health does not ſeem at firſt to be materially affected; but when the diſtemper of the ſpine has made much progreſs, many complaints come on, ſuch as difficulty in reſpiration, indigeſtion, pain, a ſenſe of tightneſs in the ſtomach, obſtinate conſtipations, purgings, involuntary diſcharge of the urine and feces, &c.

The paralytic affection of the legs is certainly owing to the particular ſtate in which the ſpinal marrow, ſurrounded by the diſeaſed vertebræ, is placed. When the diſtemper has exiſted only a ſhort time, the ligaments connecting thoſe vertebræ which form the curve are ſomewhat thickened and relaxed, and the bodies of the bones affected with a change, ſimilar to what takes place in the heads of the bones in caſes of white-ſwelling. (See White-swelling.) When the complaint has been of longer exiſtence, the ligaments are now manifeſtly thickened, and the bones more obviouſly altered, and even becoming carious. The quantity of elaſtic ſubſtance between the bodies of the vertebræ is much diminiſhed; and, after death, in advanced caſes, the bones are always found carious, while a quantity of ſanious fluid is lodged between them and the membrane inveſting the ſpinal marrow. The corpora vertebrarum, howſoever ſoftened, diſeaſed, or rendered carious they may be, are never found ſpread and enlarged in their texture. Mr. Pott was well convinced that the bones were not expanded. The diſeaſe ſeems to be very analogous to the affection of the heads of the bones in the ſcrofulous white-ſwelling, and as we know that this latter diſorder is commonly unattended with any real increaſe in the dimenſions of the diſeaſed parts of the bones, we ought indeed to expect that no ſuch change would prevail in the diſtemper now under conſideration.

The convexity of the curvature is always from within outwards, and is invariably preceded, as well as the paralytic affection of the legs, by a diſtempered ſtate of the ligaments and bones.

The only thing from which relief is ever obtained in the preſent diſtreſſing affliction, is an iſſue, made on each ſide of the ſpinous proceſſes of the affected vertebræ. The beſt mode of forming the iſſue is to rub the potaſſa cum calcé upon the ſkin until the part turns brown. To accompliſh this object in a neat manner, it is as well to cover and defend the integuments with adheſive plaſter, excepting the two longitudinal portions, about half an inch broad, which are to be converted into eſchars by the application of the cauſtic. The end of this ſubſtance is to be dipped in water, and freely rubbed on the ſituation of the intended iſſues. As ſoon as the ſkin has become quite brown, the cauſtic may be waſhed off with ſome wet tow, the adheſive plaſter may be removed, and the part covered with a linſeed poultice.

Immediately the eſchars are looſe, and can be taken away without pain, the iſſues are to be filled with peas, or kidney-beans. Theſe are to be covered with adheſive plaſter, which will confine them in their ſituation. However, as the hollows ſoon become filled up with granulations, unleſs conſiderable preſſure be made, it is generally deemed neceſſary to bind a piece of paſteboard, or a compreſs containing a bit of ſheet-lead, firmly on the ſituation of the iſſues. The preſſure thus maintained, though creative of uneaſineſs at firſt, will, in the end, ſave the patient an immenſe deal of pain; for, in conſequence of its operation, the peas or beans will ſoon form as many little hollows in the cavity of the iſſue as their own number, and into theſe the future peas may afterwards be put and retained, without the leaſt uneaſineſs, provided the ſurgeon gives particular injunctions not to allow the bandage to be ever ſlack. The preſſure ſaves the patient, in the end, a great deal of pain, which would otherwiſe be unavoidable, on account of the ſurgeon being neceſſitated to repreſs the riſing granulations in the cavity of the iſſue, by ſprinkling them with powder of cantharides, or the pulv. ex ærug. æris et ſabinæ, or even rubbing them with the cauſtic. In moſt inſtances, however, it is now and then requiſite to apply one of the above powders underneath the beans or peas. In order to apply peas advantageouſly, they ſhould be previouſly ſoftened in warm water, and connected together like beads, by paſſing a thread through their centre. Then they ſhould be allowed to become completely dry, when they are fit for immediate uſe. There ſhould always be a greater length of thread than of peas, by which means, two little portions at the ends of the peas may extend beyond each extremity of the iſſue, and be fixed there by two ſmall bits of adheſive plaſter. This little contrivance will have great effect in keeping the whole row of peas in its right ſituation. When the iſſue is more than half an inch in breadth, two rows of peas ſhould be placed in it.

It is ſaid that a ſtring of beads anſwers quite as well as one of peas or beans, and certainly it is more convenient, as, when regularly waſhed every day, it may be uſed as long as the ſurgeon thinks proper; and thus the trouble and expence of getting freſh peas or beans may be avoided.

The iſſues are to be kept open until the cure is complete; that is, until the patient perfectly recovers the uſe of his legs, or even for ſome time afterwards. Mr. Pott judiciouſly recommends the practitioner to heal at firſt only one of them.

In conjunction with the iſſues, bark, ſea-air, and ſea-bathing, are frequently proper.

There have been various contrivances propoſed for the purpoſe of affording mechanical ſupport to the ſpine. This method does not, however, promiſe to be uſeful. When the morbid affection of the corpora vertebrarum has advanced to a certain ſtate, the adjoining ſound bones, both above and below the ſeat of the diſeaſe, become approximated to each other, and at length anchyloſed. This ſalutary proceſs, if influenced at all by mechanically ſupporting the ſpine, muſt obviouſly be retarded. From this account we alſo ſee the reaſon why the projection of the ſpinous proceſſes, at leaſt in adult ſubjects, muſt always remain. In children, however, a great diminution, and even an entire removal of a certain degree of deformity, may take place during the growth of the body. Pott's Chirurgical Works, vol. iii. Cooper's Firſt Lines of the Practice of Surgery, edit. 3, part 2.

Spine, in *Agriculture*, a term ſignifying provincially the ſurface turf, ſod, or ſward of land.

Spine, a ſharp, firm, hard point which is ſent off from the woody parts of ſome ſorts of plants. It conſequently differs from a prickle, which only riſes from the bark of the plant. The ſpines in plants of this nature are produced either ſingly, as is the caſe in moſt of them; doubly, or by pairs, as in ſome particular ſorts; or in a triple manner, as in the three-thorned acacia.

Spines *of Echini*, in *Natural Hiſtory*. Theſe in their foſſile ſtate make a great appearance in the cabinets of the curious, and in the works of the learned, and are of an almoſt infinite variety of kinds; and many of them are of the ſame figures and dimenſions with thoſe of the echini now living in our own and other ſeas, and well known to us. But beſide theſe, there is an almoſt infinite variety of others, which, though allowed on all hands to be truly ſpines of ſome echini or other, yet evidently differ from thoſe of all the known recent fiſh of that name, and have certainly belonged to a ſpecies of it, of which we have not now the leaſt knowledge. Theſe, however different in ſhape from one another, yet all agree in their texture and conſtituent matter.

SPINEDA, in *Geography*, a town of Italy, in the department of the Upper Po; 4 miles N.N.E. of Sabionetta.

SPINELL, or *True Ruby*, *Spinelle* of Haüy and Broch, in *Mineralogy*. (See Gems.) The colour of this gem is red, blended with tints of blue or yellow; and it occurs in grains, in ſmall rounded fragments, and cryſtallized. The primitive form of its cryſtals is the regular octohedron, exhibiting alſo the varieties of the cuneiform octohedron, the primitive octohedron with the edges of the common baſe truncated, the ſame with all the edges truncated, and the primitive octohedron divided obliquely into two ſegments, which are turned on each other $\frac{1}{6}$th of a circle, thus forming a ſolid with alternate ſaliant and re-entering angles. The cryſtals are ſmall and very ſmall, rarely middle-ſized. The faces of the octohedron are ſmooth, and the planes of the truncatures are longitudinally ſtriated. Its luſtre, externally and internally, is brightly ſhining, vitreous. Its croſs fracture is conchoidal, its longitudinal fracture is lamellar in three directions. It varies from tranſlucent to tranſparent. It is conſiderably hard, though in this reſpect inferior to ſapphire. Sp. gr. 3.57—3.64. Before the blowpipe it is infuſible without addition, but melts with borax, acquiring a green colour. When ground to a very fine powder, it is ſoluble by long digeſtion in boiling ſulphuric acid. It was firſt analyſed by Klaproth, and afterwards by Vauquelin, with the following reſults:

	Klaproth.	Vauquelin.
Alumine -	74.5	82.47
Silex - -	15.5	0.
Magneſia -	8.25	8.78
Oxyd of iron	1.5	0.
Lime - -	0.75	0.
Chromic acid -	0.	6.18
	100.50	97.43

Although its geological ſituation is not known, it occurs imbedded in calcareous ſpar and adularia, accompanied by mica and magnetic pyrites. See Gems. See alſo Corundum. Aikin's Dict.

Mineralogiſts formerly claſſed all varieties of ruby with ſpinell, and alſo the oriental ruby or ſapphire. The cochineal-red variety of ſpinell is the Balais ruby of the jewellers, ſo called from Balachan, the Indian name of Pegu, where it is found. The violet-blue ſpinell is the almandine of Pliny; it is named from Alabanda, a town in Leſſer Aſia. The orange-yellow variety is the rubicelle ruby of jewellers. A newly diſcovered variety of ſpinell is called by Werner Salam ſtone, the name by which it is known in India; its colours are red and blue. It is cryſtallized in ſix-ſided priſms, variouſly truncated. It is in general only tranſlucent, and exhibits a pearly light on the ſurface. It is ſomewhat heavier than true ſpinell, but in other characters agrees with it. It is found in the peninſula of India.

SPINET, *Spinetto*, Ital. *Eſpinette*, Fr. from *ſpina*, a thorn, or quill, the tone being produced by a crow's quill inſerted in the tongue of a little machine called a jack. (See JACK, and TONGUE.) The inſtrument conſiſts of a cheſt or belly, made of the moſt porous and reſinous wood to be found, and a table of fir faſtened on rods, called the ſound-board, which bears on the ſides: on the table are raiſed two little prominences or bridges, in which are fixed as many pins as there are ſtrings on the inſtrument. See BRIDGE.

It is played with keys, like the virginal, or ſmall piano-forte; the long keys are for the diatonic or natural notes, and the ſhort for the flats and ſharps. See KEYS, and SCALE.

The keys, when preſſed down at the end by the finger, on the principle of the lever, make the other end throw up jacks, which ſtrike the ſtrings, and cauſe the ſound by means of the quills with which they are armed.

The thirty thickeſt ſtrings are of braſs; the others, for the more delicate tones, are of ſteel or iron-wire, faſtened at one end by hooks, and at the other on pins, by which they receive their tenſion over the bridges already mentioned.

The figure of the ſpinet is like that of the harpſichord, a horizontal harp, and the harp an inverted ſpinet. It is tuned in the ſame manner as other keyed inſtruments, by 5ths and 8ths, with or without bearings, as the tuner or the owner of the inſtrument ſhall pleaſe.

There have been ſpinets and harpſichords made for curious people with ſome or all the ſhort keys ſplit or cut in two for harmonics, or at leaſt to perfect ſome of the extraneous keys, furniſhing a different tone for F♯ and G♭, D♯ and E♭, &c. to perfect ſome of the moſt offenſive keys in common tuning. Zarlino had an inſtrument of this kind made at Venice, which we ſaw at the houſe of Percetti, the compoſer's widow, and it was afterwards ſent to England; but the mechaniſm and tone were ſo bad, that no tuning could render its ſounds agreeable. There are quarter-notes, as they are called, in the Temple organ, to three of the five ſhort keys; but except in pſalmody, or very ſlow movements, Stanley never ventured to touch them.

We have ſeen ſpinets made by Haywood, in the time of James and Charles I., with box keys for the natural notes; by Keen and Slade, in queen Anne's time, with the long keys of ebony and the ſhort of ivory; and excellent ſpinets by the two Hitchcocks, father and ſon, with ivory natural keys, and ebony or dried pear-tree for the ſharps and flats.

The ſpinet had but a ſingle ſtring to each note. As the ſpinet rivalled the virginal, the ſmall piano-forte has ſupplanted the ſpinet in the public favour; and we believe that very few have been made ſince the middle of the laſt century.

SPINIAGOR, in *Geography*, a town of Ruſſia, in the government of Viatka; 40 miles S.W. of Elabuga.

SPINIFEX, in *Botany*, from *ſpina*, a thorn, and *facio*, to make, becauſe of the thorny nature of its involucral leaves.—Linn. Mant. 2. 163. Nov. Gram. Gen. 29. t. 1. Schreb. Gen. 744. Willd. Sp. Pl. v. 4. 1129. Mart. Mill. Dict. v. 4. Brown Prodr. Nov. Holl. v. 1. 198. Juſſ. 30. Lamarck Illuſtr. t. 840.—Claſs and order, *Polygamia Dioecia*; rather *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Common Involucrum of two lanceolate, channelled, unequal, ſpinous-pointed leaves; partial of about four ſimilar ones. Flowers on awl-ſhaped cluſtered receptacles, naked above. Perianth of two equal valves, containing one or two florets. *Cor.* of two lanceolate convoluted valves, the innermoſt enfolding the organs of fructification. *Stam.* Filaments three, capillary; anthers long, linear, cloven at each end. *Piſt.* Germen oblong; ſtyles two, thread-ſhaped, longer than the glumes; ſtigmas villous, prominent. *Peric.* none, except the hardened corolla, united to the oblong, ſmooth, ſolitary *ſeed*.

On one plant the flowers are ſituated at the baſe of each receptacle, each calyx containing two florets, and the anthers are moſt perfect in one, the ſtigmas in the other. On a ſeparate plant the florets are ſolitary, all male, and numerous along the lower part of each receptacle.

Eſſ. Ch. Involucrum of two ſpinous leaves. Calyx of two valves, two-flowered. Corolla of two valves. Seed united to the hardened corolla.

Some flowers male, on a ſeparate plant.

1. S. *ſquarroſus*. Linn. Mant. 2. 300. Willd. n. 1. (Stipa ſpinifex; Linn. Mant. 1. 34. Cyperus littoreus; Rumph. Amboin. v. 6. 6. t. 2. f. 2.)—Smooth. Leaves channelled, rigid, ſpinous-pointed, rough at the edges.—Native of the ſandy ſea-ſhores of the Eaſt Indies. A large, rigid, tough, ſhrubby *graſs*, whoſe ſurface is ſmooth and glaucous. *Leaves* three or four inches long, with broad ſheathing baſes, rough-edged. *Flowers* in large, terminal, aggregate and compound heads, the ſpinous points of their receptacles and involucral leaves projecting in every direction. Theſe heads are blown to a great diſtance by the wind, and roll along the ſands with great velocity.

2. S. *longifolius*. Brown n. 1. (Cyperus; Peron, Voy. aux Terres Auſtr. v. 1. 113.)—“Smooth. Leaves flaccid, ſemi-cylindrical, unarmed, ſmooth-edged, thrice as long as the ſeed-bearing receptacle. Glumes of the male flowers rough.”—Gathered by M. Baudin, in the tropical part of New Holland. *Brown*.

3. S. *fragilis*. Br. n. 2.—“Smooth. Leaves flaccid, ſemi-cylindrical, unarmed, rough-edged, longer than the ſeed-bearing receptacle.”—Obſerved by Mr. Brown, in the tropical part of New Holland.

4. S. *ſericeus*. Br. n. 3.—“Silky. Leaves unarmed, ſmooth, like their ſheaths, at the inſide. Point of the male receptacle ſeveral times ſhorter than the ſpike.”—Found by Mr. Brown in the laſt-mentioned country, as well as in New South Wales.

5. S. *hirſutus*. Br. n. 4. Labill. Nov. Holl. v. 2. 81. t. 230, 231.—Silky. Leaves unarmed, villous as well as their ſheaths. Point of the male receptacle nearly equal to the ſpike.—Native of the ſouth coaſt of New Holland.

SPINIS. *Attachiamenta de Spinis & Boſco*. See ATTACHIAMENTA.

SPINNEY, in *Rural Economy*, a term ſignifying provincially a clump of trees, or ſmall grove or plantation.

SPINNING, the art of combining animal or vegetable fibres into threads or cords, by twiſting them together. Wool, ſilk, cotton, flax, and hemp, are the matters moſt commonly employed for ſpinning into threads; and of theſe, moſt of the vegetable fibres, except cotton, require to be wetted during the operation of ſpinning, to render them more ſupple; but cotton, wool, and ſilk, are ſpun in a dry ſtate.

The machines employed for ſpinning are of very different kinds, and adapted to the materials to be operated upon; but they have all a ſpindle, revolving with a rapid motion, to twiſt the fibres which are attached to the end of it, and are ſupplied in a regular quantity, as faſt as the twiſting motion of the ſpindle will form them into a thread; and there is alſo ſome proviſion of a bobbin upon the ſpindle, to take up and retain the thread when made.

The moſt ancient mode of ſpinning is by the ſpindle and diſtaff, and this method is the ſimpleſt of all others. The ſpindle is nothing more than a piece of hard wood, made round, and ſharp-pointed at one end, ſo that it can be made to ſpin upon its point, in the ſame manner as a child's top: the upper part is reduced to a pin or peg, and it is this part which has the fibres united to it, the lower or enlarged part being only to give ſufficient weight to make it ſpin. The ſpinner muſt be ſeated upon the ground, and after having put the diſtaff in motion upon its point, by twirling it between the hands, get it up to a rapid motion, by ſtriking it occaſionally with the hand, with a motion very ſimilar to that by which a child keeps up the motion of his whipping-top, when he draws the laſh of a whip round it.

The flax, or material which is to be ſpun, after being properly prepared, is lapped round the end of the diſtaff, which is nothing more than a ſtick that the ſpinner holds in the left hand, ſo as to be conveniently ſituated to draw off from it a few fibres at a time, with the finger and thumb of the right hand, to form the thread. The upper part of the ſpindle, which is made ſmaller, like a pin, has the ends of the fibres which are to form the thread attached to it before it is put in motion. Theſe fibres are drawn out of the bunch which is wound upon the diſtaff, and held between the finger and thumb, ſo as to be in the direction of the length of the ſpindle; therefore, when the ſpindle is once made to revolve, it twiſts theſe fibres together, to form a thread, and as faſt as the thread forms, the ſpinner draws off more flax from the diſtaff, and guides the fibres between the finger and thumb, ſo that they ſhall be regularly delivered out, and make an even thread. The motion of the ſpindle is conſtantly kept up, by ſtriking it as often as the hand can be ſpared from the operation of guiding the thread. When by theſe means as great a length of thread is formed as is convenient to reach from the end of it to the ſpindle, the thread is wound upon the outſide of the ſmall part or pin of the ſpindle, for which purpoſe the ſpinner applies the fore-finger againſt the thread, cloſe to the end of the ſpindle, and bends the thread at that part, ſo that it will be at right angles with the direction of the ſpindle, inſtead of being nearly in the direction of its length; and alſo, that it will be guided oppoſite to the middle of the pin, or ſmall part of the ſpindle, inſtead of being at the extreme end thereof. In this ſituation the motion of the ſpindle, which is continually kept up, occaſions the thread to wind up, or lap upon the pin of the ſpindle, inſtead of twiſting round upon itſelf, as in the former caſe; but when nearly all the length of thread is thus diſpoſed of, the finger is removed from the thread, and it immediately aſſumes its original direction, by ſlipping to the extreme end of the ſpindle, ſo as to be twiſted round itſelf by the motion of the ſpindle, and more fibres are now ſupplied to it from the bunch upon the diſtaff, to form a freſh length of thread. In this manner the ſpinning proceeds, until as much thread is ſpun and wound upon the pin of the ſpindle as will make a moderate ſized ball.

This ſimple and inconvenient method of ſpinning becomes very efficient, when the ſpindle, inſtead of being ſpun upon the ground, is mounted in a proper frame, and turned by a wheel and band; this forms a machine which is called the one-thread wheel, and is ſtill uſed in the country for ſpinning wool: the ſpindle is made of iron, and placed horizontally, ſo that it can revolve freely; and the extremity of the ſpindle, to which the thread is applied, projects beyond the ſupport.

The wheel which turns it is placed at one ſide, the pivots of both being ſupported in upright pieces, riſing up from a ſort of ſtool. The ſpinner puts the wheel in rapid motion by its handle, and its weight is ſufficient to continue the motion for ſome ſeconds; then walking backwards from the ſpindle, in the direction of its length, ſhe ſupplies the fibres regularly, and the motion twiſts them into a thread; but when a convenient length is ſpun, the ſpinner ſteps on one ſide, and reaches out that arm which holds the end of the thread, ſo as to alter the direction of the thread, and bring it nearly perpendicular to the length of the ſpindle, which motion gathers or winds up the thread upon the middle of the projecting part of the ſpindle. This being done, ſhe holds the thread in the direction of the ſpindle, ſo that it will receive twiſt, and retreats again to ſpin a freſh length of thread. For ſpinning wool, it is not wound round the diſtaff the ſame as flax, but the ſpinner holds a lock of it, doubled over the fore-finger, and draws away the fibres from the middle part of the lock, to do which with regularity is the great art of ſpinning by hand.

A ſpinning-machine more perfect than this is the one-thread flax-wheel, with ſpindle and flyer; it has the property of conſtantly drawing up the thread as faſt as it is ſpun, inſtead of ſpinning a length, and then winding it upon the ſpindle. For this purpoſe the ſpindle is made longer than the other, and is turned by a band and wheel; but the wheel receives motion from the foot by a ſmall treadle, becauſe the ſpinner ſits before the wheel to work the ſpindle, which is ſupported upon its two extreme ends, and near one end the flyer is fixed; this is a piece of wood curved to an arc, the vertex of which is fixed on the ſpindle, and from the extremities of the arc two arms proceed, ſo as to be parallel to the ſpindle, and at ſuch a diſtance from it as to admit a wooden bobbin to be fitted looſely upon the ſpindle; and at the ſame time the arms of the flyer can revolve round the bobbin without touching it. The end of the thread is faſtened to the bobbin, and conducted through a hook fixed in the flyer, ſo that it proceeds from the circumference of the bobbin to this hook, in a direction perpendicular to the bobbin, but turns round the hook ſo as to come into the direction of the ſpindle. The thread is then conducted through a perforation made in the centre of the end of the ſpindle or pivot, upon which it revolves, and to this end of the thread the fibres are ſupplied. The twiſting motion given by the revolution of the ſpindle forms them into a continuation of the thread, which is gathered up upon the bobbin as faſt as the ſpinner lets it go through her fingers, by a tendency which the bobbin has to turn ſlowly, at the ſame time that the flyer to which the thread is hooked is revolving rapidly round the bobbin. For this purpoſe a ſtring is paſſed round a ſmall neck upon the bobbin, and one end of the ſtring being faſtened to the frame, the other has a ſmall weight to draw it tight round the neck of the bobbin, and occaſion friction. In other ſpinning-wheels, a ſecond band from the great wheel is made to turn the bobbin more ſlowly than the ſpindle. The thread which paſſes over the hook of the flyer is rapidly carried round the circumference of the bobbin; but as the bobbin follows the motion of the flyer, it only winds up as much thread upon the bobbin as the difference of the two motions;

and this tendency to wind up can be increaſed or diminiſhed at pleaſure, by the friction which is occaſioned by the ſtring or band which paſſes round the neck of the bobbin. When the winding-up of the thread upon the bobbin has accumulated a ridge of thread upon it oppoſite to the hook in the flyer, the thread muſt be ſhifted to another hook oppoſite to a different part of the bobbin, for which purpoſe the arms of the flyer are furniſhed with different hooks, and this muſt be repeated ſeveral times, until the whole length of the bobbin is filled; it is then taken off to be reeled, and replaced by another empty bobbin.

An improvement was made in the ſpinning-wheel by Mr. Antis ſome years ago, which was an application of what ſir Richard Arkwright had before invented. The object is to obviate the neceſſity of ſtopping the wheel to remove the thread from one hook to another, in the manner juſt deſcribed. For this purpoſe, the bobbin is made to move regularly backwards and forwards upon the ſpindle a ſpace equal to its length, ſo that every part will, in ſucceſſion, be preſented oppoſite the hook over which the thread paſſes, and thus receive the thread regularly upon the whole length of the bobbin. The additional parts neceſſary for producing this movement are as follow: a pinion of only a ſingle leaf is made to project from the extremity of the pivot of the great wheel, or a worm or endleſs ſcrew formed on the end pivot, will anſwer the ſame purpoſe, which is to actuate a wheel of ſeven inches diameter, and ninety-ſeven teeth; therefore ninety-ſeven revolutions of the great wheel will produce one revolution of this ſmaller wheel; upon the face of which a circular ring of wire is fixed, and ſupported from the wheel by ſix legs, ſo as to be oblique to the plane of the wheel, as it touches it at one part, and at the oppoſite ſide of the ring projects nearly three-fourths of an inch. This ring of wire gives motion to an upright lever, about fifteen inches long, and moving on a centre at three inches from its lower extremity, where it has a pin fixed in it, and reſting againſt the oblique ring of wire; therefore, when the wheel turns round, it communicates a ſmall motion to the lever, in conſequence of its obliquity to the plane in which it revolves. The upper end of the lever is connected to an horizontal ſliding-bar, ſituated beneath the ſpindle, and having an upright piece of braſs, which works in the notch of a pulley, formed on the end of the bobbin, and drives the bobbin backwards and forwards upon the ſpindle, according as the oblique ring of wire forces the pin at the lower end of the lever in or out, when the wheel moves round. To regulate and return this alternate motion, a ſmall weight hangs by a line to the ſliding-bar, and, paſſing over a pulley, riſes and falls as the bobbin recedes and advances, and tends conſtantly to keep the pin at the lower end of the lever in contact with the wire. It is evident, from this deſcription, that one ſtaple only is wanted to the arms of the flyer, which being placed near the extremity, the thread paſſes through it, and by the motion of the bobbin, is laid regularly upon it from one end to the other.

The invention has alſo another advantage over the old method, which always winds the thread in ridges upon the bobbin; and if the thread breaks in reeling the yarn, the whole bobbin may as well be thrown away, becauſe the thread cannot eaſily be found again; but this improved wheel always winds the threads acroſs upon one another, by which means the end can never be loſt.

In order to regulate the friction on the bobbin, and retard its motion in a greater or leſs degree at pleaſure, there is a neck of braſs or ſteel faſtened to one end of it, and embraced by a kind of ſmall vice, or pincers, fixed to the ſliding-bar. This vice muſt be made either with two elaſtic ſprings with wooden tops, or of wood wholly, and faced with leather; but if made of wood only, then a ſpring muſt be made beneath the ſhoulder of the ſcrew, to anſwer the ſame purpoſe. By tightening this ſcrew more or leſs, the friction on the bobbin may be regulated to the greateſt nicety, provided the ſprings are of a ſtrength rightly proportioned to their functions. It will readily appear, that all this may be done without the leaſt effect on the velocity of the whole machine, as thereby nothing is added to the general friction ſo as to obſtruct it.

It was not until the latter end of the laſt century, that ſpinning-machines of greater powers were conſtructed; but all threads were ſpun by one of the machines which we have deſcribed; the firſt being uſed for cotton and wool, and the other, with the bobbin and flyer, for flax; but for very coarſe threads, two ſpindles were applied to the latter machine, and the ſpinner having the wool wound round a band, tied it round her waiſt, inſtead of winding it upon a diſtaff, and was thus able to draw out fibres with each hand, and ſupply two ſpindles. And of the other ſimple ſpindles, ſeveral were made to turn together by the movement of one large horizontal wheel, around which the ſpindles were arranged in directions radiating from the centre, and each ſpindle received a rapid motion by the contact of the edge of the large wheel, which was turned round by one perſon. The ſpinners each ſtood oppoſite to his reſpective ſpindle, ſo as altogether to occupy a large apartment, and by this means they could do much more work than formerly, having none of the interruptions of turning the wheel.

The firſt improvement of any importance in ſpinning, was that of the ſpinning-jenny, invented by Hargraves, as related in our article COTTON; and the machine itſelf will be deſcribed under the article WOOLLEN *Manufacture*. This machine conſiſts of a number of ſpindles, ſimilar to thoſe of the one-thread wheel, which are all mounted in a perpendicular direction in the ſame frame, and turned round by one large wheel, ſituated in an horizontal direction, and put in motion by a crank at the upper end of its ſpindle. The threads from each ſpindle are conducted nearly in an horizontal direction, but being quite at the point or upper extremity of the ſpindles, do not wind upon the ſpindles, but will receive twiſt, becauſe the threads ſlip over the top of the ſpindles as they revolve. The threads are guided between two rulers of wood, called the *claſps*, inſtead of the finger and thumb of the ſpinner. Theſe rulers are made to fit together, ſo as to hold the fibres between them, and are fitted up with wheels at the end to run upon the frame, and thus advance or retreat at pleaſure from the ſpindles. It was not attempted with this machine to ſpin a finiſhed thread immediately from the lock of wool or cotton, but coarſe and looſe threads are previouſly prepared on the hand-wheel, which can be done with great rapidity, and the coppins or balls of theſe looſe threads are placed in the jenny, and conducted, firſt between the claſps or rulers before mentioned, and then to the ſpindles. By this means, when the carriage of the claſps is drawn backwards from the ſpindles, the claſps being ſeparate, the threads draw between them from off the coppins, and at the ſame time that portion of each thread which is between the claſps and the ends of the ſpindles, receives its twiſt; but having drawn out a certain length of each thread in this manner, the claſps are ſhut together; and the motion of the ſpindles, as alſo the retreat of the claſps, is continued, by which means the threads are ſtretched out to their intended fineneſs, and being thus finiſhed, the threads are wound upon the ſpindles, by being brought oppoſite to the middle part of the ſpindles by a rail of wood, called the *faller*, which moves upon centres, ſo as to deſcend horizontally before all the ſpindles, and depreſs all the threads together, ſo that they will wind up by the motion of the ſpindles, and as they wind, the claſps return towards the ſpindles. The operations are then again repeated, and thus continued, until the coppins or balls of thread, wound upon the ſpindles, acquire their proper ſize.

The next improvement in ſpinning-machines was the introduction of the ſlubbing-machine, or billy, for preparing the rovings for the jenny; an operation which was at firſt performed by the hand-wheel. This machine has ſimilar parts to the jenny, but they are differently arranged, to adapt it to ſpin the wool as it comes from the carding-machine, in the ſtate of cardings, which are locks of wool drawn out to about the ſize of candles, and from two to three feet in length. For this purpoſe the ſpindles are made to travel on the carriage, and the claſps ſtand ſtill, being the reverſe of the jenny. The cardings are laid upon an endleſs cloth, which revolves over two rollers, and lies in an inclined poſition at the end of the machine; and one carding is laid upon the cloth oppoſite to each ſpindle, the ends being pieced with freſh cardings by children, as faſt as the ſpindle works them up. A roller preſſes down upon the cardings, to hold them faſt upon the feeding-cloth, and to make them move with it; and juſt beyond this roller the claſps are fixed to hold the rovings, when the proper lengths are drawn out by the retreating of the ſpindles, which, as before ſtated, are ſituated in the carriage. The operation of the billy is the ſame as that of the jenny, *viz.* that the carriage is drawn out, and the feeding-cloth revolves over its roller to give out the cardings until a certain length: the claſp is then ſhut down, and the further extenſion of the threads is produced by ſtretching; which being done, the threads are wound upon the ſpindles.

The inventions of ſir Richard Arkwright ſoon ſuperſeded theſe machines. His principal invention in the ſpinning was the introduction of the rollers, to draw out or extend the fibres to their full length, which is by this means much more perfectly performed than by the fingers of the ſpinner. For the immediate twiſting of the thread, he adopted the ſpindle, bobbin, and flyer of the old flax-wheel, placed in a vertical poſition, but added to it the important improvement of raiſing and lowering the bobbin, to diſtribute the thread regularly and equally upon all the length of it, the ſame which we have before deſcribed as being applied by Mr. Antis to the common ſpinning-wheel. A full deſcription of this machine, which is called the water ſpinning-frame, will be found in the article *Cotton* MANUFACTURE, *Plate* IX. *Cotton Manufacture.*

The ſpinning-jenny was again introduced, and rendered equal, and for ſome purpoſes ſuperior, to the water-frame, by Mr. Crumpton, who combined with it the ſyſtem of rollers of ſir Richard Arkwright, and called it the mule. It is alſo fully deſcribed under *Plate* XI. *Cotton Manufacture.* See *Cotton* MANUFACTURE.

The great ſucceſs which attended the ſpinning of cotton by theſe machines, induced many perſons to attempt the ſpinning of flax and wool by ſimilar means. Short wool, for the manufacture of cloth, is ſpun by the billy and jenny; but flax and long wool for worſted require very different treatment from cotton and ſhort wool, particularly the flax, owing to the great length of the fibres, and to their being of ſuch irregular lengths: in conſequence, when they are extended by the rollers, on Arkwright's principle, ſome fibres will be broken, if the diſtances between the rollers is too ſmall; and on the other hand, if the diſtance is too great, the fibres will not be properly extended. The latter, however, is the leaſt evil of the two; and, in conſequence, the ſpinning-frames for flax have the rollers, between which the extenſion or drawing out is effected, placed at a diſtance of from 14 to 18 inches between the firſt two pair of rollers, through which the flax paſſes; the next two pair ſix or eight inches; after which it is paſſed between the third pair of rollers at a diſtance of five or ſix inches, and then delivered to the ſpindles, which are ſimilar to thoſe of the water-frame, but placed in an inclined poſition. The rollers are made in a very different manner from thoſe for cotton, being only narrow wheels juſt wide enough to receive the fibres of flax between them; and the fibres are prevented from getting out ſideways by ſmall tin ſpouts, through which the flax paſſes, as the rollers draw it forwards. The reaſon of this is, that the flinty ſurface of the flax would ſoon wear a hollow part round a plain roller, which would then let the flax ſlip through; but the narrow wheel wears down equally over the whole breadth of its edge. The lower pair of theſe rollers, or wheels, revolves in a ſmall trough of water, in the ſame manner as a grind-ſtone, and thus keeps the flax conſtantly wet, which is neceſſary, in order to ſoften the fibres, and make them ſpin into a firm and ſmooth thread.

Worſted is alſo ſpun in a frame reſembling the water-frame of Arkwright, from which it only differs in the relative diſtances of the rollers, by which the drawing out or extending of the fibres is effected.

Meſſrs. Clarke and Bugby obtained a patent in 1806, for improvements in a machine for ſpinning hemp and flax, which is intended to be worked by hand labour, and to be at ſuch a ſmall expence, as to bring it within the reach of ſmall manufacturers. The inventors ſtate it to be conſtructed upon ſuch ſafe and eaſy principles, that no length of experience is neceſſary to enable children to work it; and that it occupies ſo little ſpace, that the machines may be placed in ſmall rooms, out-buildings, or other cheap places. To effect the above purpoſes, it was neceſſary to get rid of the flyer fixed upon the ſpindle uſed in the old machinery for ſpinning hemp or flax, which additions require a power in proportion of five to one; and alſo to ſurmount the difficulty which ariſes from the want of elaſticity in theſe ſubſtances, and which prevents them from being ſpun, by ſtretching out at the ſame time that the thread is twiſted, in the manner of the mule or jenny.

Theſe patentees recommend a machine, which is in fact a mule with certain modifications; and to give the effect of elaſticity in the fibres, they have two methods. The moſt ſimple, and that which they particularly recommend, is to provide a holder of large wire for every ſpindle, which holders are ſeveral inches in length, fixed in an arbor or ſhaft, that extends from one end of the carriage to the other.

This arbor or ſhaft, with the holders, may be conſidered as an enlarged and improved ſubſtitute for what is called the faller in the mules or jennies for ſpinning cotton, and the wire-holders fixed therein have elliptical eyes at their extremities, through each of which a thread is conducted in its paſſage from the rollers which draw out the thread to its ſpindle. The wire of which the holder is made, after forming the elliptical eye, is left or extended beyond the uppermoſt part, ſomething in the manner of a cork-ſcrew, ſo that the yarn may be conveniently ſlipped in when occaſion may require it. Theſe holders for each thread are for the purpoſe of keeping the yarn in a ſtate nearly vertical over the tops of the ſpindle, when the carriage which contains them is coming out; and as they will readily yield or ſpring from the vertical poſition, they have the ſame effect as elaſticity in the fibres of the ſubſtance which is to be ſtretched out; but the wires being removed from the vertical ſituation at the beginning of the return of the carriage, and thrown into nearly a horizontal poſition, by inclining the ſhaft into which they are all fixed, they bring the yarn below the tops of the bobbins or quills which are fixed upon the ſpindles, which will then wind up the threads upon them when the ſpindles are turned round, and then the wire-eyes being regularly curved, and raiſed up again by the motion of an elliptic wheel, which is turned round by the machine, they diſtribute the yarn regularly upon the bobbins or quills, and prevent it from hinkling, and improperly doubling or twiſting together. Another method of compenſating for the want of elaſticity in hemp and flax, is to fix a round bar of wood, about an inch and a half in diameter, the whole length of the carriage, about three or four inches above the tops of the ſpindles, ſo that the outer ſurface, or that next the perſon who works the machine, may be perpendicular, or nearly ſo, over the tops of the ſpindles, the inner ſide having pieces of wood or metal fixed or nailed thereto, leaving only ſmall ſpaces or notches between each, for the yarn to paſs through. The uſe of theſe pieces is to prevent the threads from getting together and entangling. Every thing relating to the wire-holders before mentioned, and the arbor to which they are affixed, muſt be applied in concert with theſe pieces of metal, which form a ſeparation between the threads.

The art of ſpinning, which nature has given to many animals of different kinds for their preſervation, and other purpoſes, is not confined to the inhabitants of the earth or air alone, but is even extended to thoſe of the ſea. M. Reaumur has ſhewn, by a ſeries of curious experiments, that the common muſcle, and ſome other ſhell-fiſh of the ſea, poſſeſs it in a great degree of perfection. See Muscle.

But he obſerves, that though the workmanſhip is the ſame, the manner of producing it is very different. Spiders, caterpillars, and the like, make threads of any length that they pleaſe, by making the viſcous liquor, of which they are formed, paſs through a fine perforation in the organ appointed for this ſpinning: but the way in which the muſcles form their threads is very different, as the former reſembles the work of the wire-drawer, ſo does this that of the founder, who caſts metals in a mould. The canal of the organ deſtined for the muſcle's ſpinning, which, from its ſhape, is commonly called its tongue, is the mould in which its thread is caſt, and gives it its determinate length. Mem. Acad. Par. 1711.

Spinning-*Wheel*, in *Rope-making*, for twelve ſpinners to ſpin yarn at the ſame time, is about five feet in diameter, and is hung between two poſts fixed in the ground: on its top is fixed a ſemi-circular frame, called the head, which contains twelve whirls, that turn on iron ſpindles, with hooks to their front ends to hang the hemp on, and are worked by means of a leather band encircling the wheel and whirls. The whirls are made to run with a truer motion when the head on the riſing ſide of the band has a larger ſegment of a circle than the falling ſide; or in other words, let the baſe part of the head be longer from the middle than the oppoſite or falling ſide, by which means the band will be kept equally tight over the whirls, and conſequently the motion be alike to all. N.B. Heads made in this manner have the wheel turned always the ſame way.

SPINO, in *Geography*, a town of Italy, in the department of the Upper Po; 8 miles W.N.W. of Crema.

SPINOLA, Ambrose, in *Biography*, one of the moſt celebrated generals of his time, was born in 1569. His family was noble, and originally from Genoa. His brother Frederic, general of the gallies ſtationed in the Low Countries, in the ſervice of Spain, engaged him to bring a body of 9000 Italian and Spaniſh veterans into Flanders, where he ſoon diſtinguiſhed himſelf by his valour and good conduct. He marched againſt the famous prince Maurice, and it was agreed between him and king Philip that he himſelf ſhould pay his own ſoldiers, to be reimburſed afterwards; by which regulation, while the other Spaniſh troops were extremely diſorderly and mutinous for want of their pay, thoſe under his command were patterns of obedience and ſtrict diſcipline. He was commiſſioned to raiſe ſome additional regiments, in order that he might undertake, in concert with his brother, ſome important expedition, but the death of the brother, in a ſea-fight with the Dutch, put an end to the project. The town of Oſtend had been in a ſtate of ſiege nearly three years, and ſmall progreſs had been made towards its reduction; for which reaſon the archduke Albert, governor of the Netherlands, reſolved to commit the whole management of it to Spinola. Before he took upon himſelf the management of this buſineſs, he ſent ſome officers to examine the works, and though they differed in opinion as to probability of ſucceſs, the love of glory induced him to accept the charge. His plans ſucceeded, and the place ſurrendered after the end of the third year, having, it is ſaid, coſt the lives of 100,000 men. Spinola was rewarded with honours of every kind, and at the concluſion of the campaign, he went to Madrid, and obtained the rank and office of camp-marſhal-general, and commander-in-chief of the Spaniſh and Italian troops. He paſſed through Paris, and had an interview with Henry IV., by whom he was interrogated as to the plan of the enſuing campaign, of which he gave a faithful account. The king, taking for granted that his intention was to deceive, wrote to prince Maurice juſt the contrary of what he had heard from Spinola, and afterwards, when he found his miſtake, he ſaid, "Others deceive by telling falſehoods, but this man by telling the truth." Spinola now put into execution his deſign of carrying on the war into the enemy's country, and croſſing the Rhine, he penetrated into Overyſſel, where he took ſeveral places, in which he left conſiderable garriſons. His progreſs was at length ſtopt by prince Maurice, and theſe two great commanders exhauſted the whole art of war during that and the following campaign, in keeping each other in check. Both parties at length becoming weary with war, a congreſs was appointed in 1608 to treat of peace at the Hague, and Spinola was at the head of the deputies on the part of the archduke. Wherever he came the people flocked to gain a ſight of ſo celebrated a commander, and they were met at Dordrecht by prince Maurice, who treated his antagoniſt with the greateſt reſpect. The difficulties ariſing in the progreſs of the negociation were ſo great, that a truce only could be concluded. In 1621 the war was renewed, on account of a diſputed ſucceſſion to the countries of Cleves and Juliers, and Spinola being placed at the head of an army, penetrated into the latter country and reduced its capital. Prince Maurice was again his opponent, who was not able to prevent the fall of Cleves, or the inveſtment of the ſtrong town of Breda. While this ſiege was going on, prince Maurice died, and Spinola was brought into a dangerous ſtate of health. The ſiege was, however, carried on with great vigour, and the town was defended with equal reſolution. At length, it becoming evident that the garriſon could not hold out any longer, Spinola, in admiration of their valour and perſeverance, offered them the moſt honourable terms of capitulation. Theſe were accepted, and the garriſon, greatly reduced, marched out. Spinola drew up his army to ſalute them, and as they paſſed, he paid particular compliments to the governor and principal officers. He diſtributed money among the ſoldiers, provided with the utmoſt attention for the cure of the ſick and wounded, and conveyed the reſt in the moſt commodious manner poſſible to the next fortreſs. Having fulfilled the duties of a hero, he reſigned his command, as having no longer an equal foe in the field with whom he could contend. In 1627, paſſing from Antwerp to Madrid, he took Rochelle in his way, in order to witneſs the memorable ſiege of that place. Richelieu conſulted him on the beſt means of bringing it to a concluſion. "Shut the port," he ſaid, "and open the hand;" meaning thereby, that the beſiegers ſhould be liberally treated.

The court of Spain recalled Spinola from the Low Countries in 1629, and ſent him into Italy, where he in the following year took Caſal. The citadel, however, remained in the hands of the French, owing to the impediments thrown in his way by orders from Madrid. The anxiety and vexation which this circumſtance occaſioned, co-operating with diſeaſe, put an end to his life in the ſame year, at a moment when he was at the ſummit of his military reputation. It is ſaid that his great antagoniſt, prince Maurice, gave this teſtimony to his character, when being aſked who was the firſt captain of the age, replied, "Spinola is the ſecond."

SPINOLETTA, in *Ornithology*, the name of a ſmall bird of the lark kind, the *alauda ſpinoletta* of Linnæus, called *tordino* by the Venetians, and ſeeming to be the *ſtopparola*, as alſo the *griſola* and *ſpipola*, of Aldrovandus. It is ſmaller than the common lark; its head, neck, ſhoulders, and back, are of a greyiſh colour, with an admixture of green; its breaſt and belly white, and its throat ſpotted: the female differs from the male, in that her belly is yellow; the wing-feathers are of a duſky brown, with whitiſh or yellowiſh edges; its tail is moderately long, and part of the feathers are ſnow-white, the reſt brown or blackiſh; the length of the heel diſtinguiſhes this bird from all others, except the lark kind, and it differs from all the ſpecies of larks in the colour of its beak and legs, which are black. It is common in the markets of Venice and other places. Ray.

SPINOSA, in *Zoology*, the name by which the Italians call the porcupine.

SPINOSE Leaf, among *Botaniſts*. See Leaf.

SPINOSI Pisces, in *Ichthyology*, ſuch fiſhes as have ſome of the rays of their back fins running out into thorns and prickles, as the perch, &c. See Fish.

SPINOZA, in *Biography*. See the next article.

SPINOZISM, or Spinosism, the doctrine of Spinoza; or, atheiſm and pantheiſm propoſed after the manner of Spinoza.

The great principle of Spinoziſm is, that there is nothing properly and abſolutely exiſting, but matter and the modifications of matter; among which are even comprehended thoughts, abſtract and general ideas, compariſons, relations, combinations of relations, &c.

Benedict de Spinoza, or Eſpinoza, was a man well known in Holland. He was born at Amſterdam, in the year 1632, being a Jew both by deſcent and education; but at an early period of his life he manifeſted ſuch diſſatisfaction with the religion of his fathers, and advanced opinions ſo contrary to their eſtabliſhed tenets, that a ſentence of anathema was pronounced againſt him by his brethren. Having been excommunicated from the ſynagogue, ſome Chriſtians, who were attached to him, afforded him an aſylum, and gave him an opportunity of acquiring a knowledge of the Latin and Greek languages, and of ſtudying the Carteſian philoſophy. But as he ſtill continued with great vehemence to attack the religion of his countrymen, they attempted firſt to ſilence him by bribe, offering him an annual penſion of 1000 florins, and afterwards to take him off by aſſaſſination. Both theſe meaſures proving ineffectual, they accuſed him, before the magiſtrate, of apoſtacy and blaſphemy; and he was baniſhed from the city. In his exile, he ſtudied mathematics and natural philoſophy, and procured a ſubſiſtence by poliſhing optical glaſſes. He reſided chiefly at Rhenburg, where he was often viſited by the followers of Deſcartes, who conſulted him on difficult queſtions. At their requeſt he publiſhed, in 1664, "The Principles of the Carteſian Philoſophy demonſtrated geometrically," with an appendix, containing metaphyſical opinions altogether inconſiſtent with the doctrine of Deſcartes. In order to eſcape the odium which was occaſioned by this publication, he retired to a village not far from the Hague, whither he was followed by many of his countrymen and foreigners, who were inclined to adopt his doctrines. The elector palatine invited him to occupy the chair of philoſophy at Heidelberg; but apprehending that his liberty would be abridged, he declined the propoſal, and continued to live in retirement, with great ſobriety and decency of manners, until a conſumption brought him to an early end, in the year 1667.

Spinoza compoſed ſeveral books in Latin; the moſt celebrated of which is his "Tractatus Theologico-Politicus," printed at Amſterdam in 1670, in which he attempts to overturn the foundation of all religion: the book, accordingly, was condemned by a public decree of the States; though it has ſince been ſold publicly, and even reprinted, both in Latin and French, in that country, and in Engliſh at London.

In this work Spinoza inſinuates, that all religions are only political engines, calculated for the public good, to render the people obedient to magiſtrates, and to make them practiſe virtue and morality.

He does not here lay down his notion of the Deity openly, but contents himſelf with ſuggeſting it. In his "Ethics demonſtrated geometrically," publiſhed among his poſthumous works, he is more open and expreſs; maintaining, that God is not, as we imagine him, an infinite, intelligent, happy, and perfect Being; nor any thing but that natural virtue, or faculty, which is diffuſed throughout all creatures.

His other poſthumous treatiſes are entitled "Politics," "On the Improvement of the Underſtanding," "Epiſtles and Anſwers," and a "Hebrew Grammar." The various impieties contained in theſe treatiſes excited general indignation; and refutations were iſſued by writers of all religious perſuaſions, who concurred in amply expoſing the empty ſophiſms, the equivocal definitions, the falſe reaſonings, and all the abſurdities with which his writings abounded.

The life of Spinoza has been accurately written by Colerus, whoſe performance was publiſhed at the Hague in 8vo. in 1706. But a more ample and circumſtantial account of this ſingular man has been given by Lenglet du Freſnoy, and is prefixed to Boulainvilliers's Expoſition of the Doctrine of Spinoza, which was publiſhed at Amſterdam, in 12mo., in 1731. Freſnoy republiſhed the work of Colerus, and added to it ſeveral anecdotes, borrowed from a Life of Spinoza, written by Lucas, a phyſician at the Hague.

The learned Fabricius, in his Bibliotheca Græca, lib. v. part iii. p. 119, and Jenichen, in his Hiſtoria Spinoziſmi Lehnhofiani, p. 38—72, have given an ample liſt of thoſe writers who have refuted the ſyſtem of Spinoza. Witſius in Holland, Majus in Germany, and De la Mothe in England, wrote againſt his Tractatus; but Bredenburg, according to Mr. Bayle, ſucceeded beſt on this ſubject; who, however, is ſaid to have been afterwards a convert to Spinoziſm, and to have written a demonſtration of the truth of it: a refutation of his defence by Iſaac Orobio, a learned Jewiſh phyſician at Amſterdam, was publiſhed in 8vo. 1703. See alſo Buddeus's Theſes de Atheiſmo et Superſtitione, c. i. ſect. 26; and Fabricius's Syllab. Script. de Verit. Relig. Chriſt. p. 357, &c. Mr. Bayle, and above all Dr. Clarke and Dr. Cudworth, have diſtinguiſhed themſelves by their refutation of the ſyſtem of Spinoza. See Bayle's Dict. art. *Spinoza*, and Clarke's Demonſtration of the Being and Attributes of God, p. 25—45, &c. ed. 1725. Cudworth's Intellectual Syſtem.

Spinoza, in his Tractatus above-mentioned, is very full on the ſubject of the authors of the ſcriptures; and endeavours to ſhew, that the Pentateuch is not the work of Moſes; contrary to the common opinion, both of the Jews and Chriſtians. He has alſo his particular ſentiments as to the authors of the other books. This part of the work has been anſwered by Mr. Huet, in his Demonſtratio Evangelica; and by M. Simon, in his Hiſt. Crit. du Vieux Teſt. See PENTATEUCH.

Spinoziſm is a ſpecies of naturaliſm, or pantheiſm, or hylotheiſm, as it is ſometimes called, *i. e.* of the dogma which allows of no other God but nature, or the univerſe; and, therefore, makes matter to be God. Accordingly, Buddeus, in a diſſertation "De Spinoziſmo ante Spinozam," proves at large, that Spinoza's doctrine of God and the world, is far from being his own invention, but that it had been held by many philoſophers of different ſects, both among the Chaldeans and Greeks. It is certain, the opinion of the Stoics, and of thoſe who held an *anima mundi*, was not far from it. Lucan introduces Cato diſcourſing thus:

> "Eſtne Dei ſedes niſi terra, et pontus, et aër,
> Et cœlum, et virtus? ſuperos quid quærimus ultra?
> Jupiter eſt quodcunq; vides, quocunq: moveris."
> Luc. Pharſ. l. 9. v. 578.

Strato likewiſe, and others among the Peripatetics, maintained ſomething very like it; and, what is more, though no ancient ſect ſeems farther removed from Spinoziſm than the Platonic, as they attributed the greateſt freedom to God, and carefully diſtinguiſhed him from matter; yet Gundlingius has proved at large, that Plato gave matter much the ſame origin with Spinoza. But the ſect that approached neareſt to Spinoziſm was that which taught, that all things were one, as Xenophanes the Colophonian, Parmenides, Meliſſus, and eſpecially Zeno Eleates; whence it obtained the name of the "Eleatic Syſtem of Atheiſm." To the ſame may alſo be reduced the opinion of thoſe, who held the firſt matter for God, as Amalricus and David of Dinantum. Add, that the ſect of Foe in China and Japan, and that of the Soufi in Perſia, and that of the Zindikites in Turkey, are found to philoſophize much after the manner of Spinoza.

The impious ſyſtem of Spinoza was ſo ingeniouſly maintained, that it found many patrons in the United Provinces, among whom were Lewis Meyer, who republiſhed Spinoza's works, and who himſelf wrote a work entitled "Philoſophy the Interpreter of Scripture," and Van Leenhof, an eccleſiaſtic of Zwoll, who wrote a piece entitled "Heaven in Earth," of the doctrine of which he was obliged to make a public recantation. Others, under the pretence of refuting Spinoza, ſecretly favoured his ſyſtem.

The chief articles in Spinoza's ſyſtem are reducible to theſe: that there is but one ſubſtance in nature; and that this only ſubſtance is endued with an infinite number of attributes, among which are extenſion and cogitation: that all the bodies in the univerſe are modifications of this ſubſtance, conſidered as it is extended; and that all the ſouls of men are modifications of the ſame ſubſtance, conſidered as cogitative: that God is a neceſſary and infinitely perfect Being, and is the cauſe of all things that exiſt, but is not a different being from them: that there is but one being, and one nature; and that this nature produces within itſelf, by an immanent act, all thoſe which we call creatures: and that this being is at the ſame time both agent and patient, efficient cauſe and ſubject; but that he produces nothing but modifications of himſelf.

As Spinoza taught, that there is no difference of ſubſtances, he maintained, that the whole and every part of the material world is a neceſſary exiſting being, and that there is no other God, but the univerſe: and, moreover, ſince it is abſolutely impoſſible for any thing to be created or produced by another, and alſo abſolutely impoſſible for God to have cauſed any thing to be in any reſpect different from what it now is; every thing that exiſts muſt needs be ſo a part of the divine ſubſtance, not as a modification cauſed in it by any will or good pleaſure or wiſdom in the whole, but as of abſolute neceſſity in itſelf, with reſpect to the manner of the exiſtence of each part, no leſs than with reſpect to the ſelf-exiſtence of the whole; conſequently the material world, and every part of it, with the order and manner of being of each part, is, upon this ſcheme, the only ſelf-exiſtent, or neceſſarily exiſting being.

And he alſo maintains, that motion, as a dependent being, has been eternally communicated from one piece of matter to another; and, therefore, without having at all any original cauſe of its being, either within itſelf or from without: this, Dr. Clarke has proved to be a plain contradiction, and conſequently, motion muſt of neceſſity be originally cauſed by ſomething that is intelligent, or elſe there never could have been any ſuch thing as motion in the world; and, therefore, the ſelf-exiſtent being, the original cauſe of all things, muſt of neceſſity be an intelligent being. Hence it follows, that the material world cannot poſſibly be the original ſelf-exiſtent being. For ſince the ſelf-exiſtent being is intelligent, and the material world plainly is not ſo, it follows, that the material world cannot poſſibly be ſelf-exiſtent.

Agreeably to Spinoza's ſyſtem, he is led to maintain that the ſupreme cauſe is a neceſſary agent, and, therefore, that no thing, or mode of exiſtence of any thing, could poſſibly have been in any reſpect different from what it now actually is; becauſe, he ſays, from an infinitely perfect nature, infinite things in infinite manners muſt needs proceed: if any thing could poſſibly be otherwiſe than it is, the will and nature of God muſt be ſuppoſed capable of change; and if all poſſible things in all poſſible manners do not always and neceſſarily exiſt, they never can all exiſt, but ſome things that do not exiſt, will ſtill always be poſſible only, and never can actually exiſt; and ſo the actual omnipotence of God is taken away. To this reaſoning Dr. Clarke replies, that the firſt argument is a plain begging of the queſtion; for, that an infinitely perfect nature is able indeed to produce infinite things in infinite manners, is certainly true; but that it muſt always actually do ſo, by an abſolute neceſſity of nature, without any power of choice, either as to time, or manner, or circumſtances, does by no means follow from the perfection of its nature, unleſs it be firſt ſuppoſed to be a neceſſary agent, which is the very queſtion begged that was to be proved.

The ſecond argument, he ſays, is, if poſſible, ſtill weaker; for, how does it follow, if God, according to his eternal unerring purpoſe and infinite wiſdom, produces different things at different times, and in different manners, that, therefore, the will and nature of God are changeable? It might exactly as well be argued, that if God (according to Spinoza's ſuppoſition) does always neceſſarily produce all poſſible differences and varieties of things; therefore his will and nature are always neceſſarily infinitely various, unequal, and diſſimilar to themſelves.

And as to the third argument, it is juſt ſuch reaſoning as if a man ſhould argue, that if all poſſible eternal duration be not always actually exhauſted, it can never be all exhauſted; and that, therefore, ſo the eternity of God is taken away: a mode of arguing, the weakneſs of which muſt be diſcerned by every one at firſt ſight. Beſides, the aſſertion itſelf, that no thing, or mode of exiſtence of any thing, could poſſibly have been made in any reſpect different from what it is, is ſo palpably abſurd and falſe, ſo contradictory to experience and the nature of things, and to the moſt obvious and common reaſon of mankind, that of itſelf it immediately, and upon the firſt hearing, ſufficiently confutes any principle of which it is a conſequence. For all things in the world appear plainly to be the moſt arbitrary that can be imagined, and to be wholly the effects not of an abſolute neceſſity of nature, but merely of a neceſſity of fitneſs, or of wiſdom and choice. Moreover, Spinoza maintaining that the ſupreme cauſe is a neceſſary agent, is conſtrained to expoſe all final cauſes as the fictions of ignorant and ſuperſtitious men; and ſo laugh at thoſe who are ſo fooliſh and childiſh as to fancy, that eyes were deſigned and fitted to ſee with, teeth to chew with, food to be eaten for nouriſhment, the ſun to give light, &c. a mode of arguing to which reply is needleſs. See the article GOD.

Againſt Spinoza's ſyſtem it is alleged by Mr. Bayle, 1. That it is impoſſible the univerſe ſhould be but one ſubſtance, ſince every thing that is extended muſt neceſſarily have parts, and what has parts muſt be compounded. And as the parts of extenſion do not ſubſiſt in each other, it follows either that extenſion in the general is not ſubſtance, or that every part of extenſion is a different ſubſtance. Now, according to Spinoza, extenſion in general is an attribute of ſubſtance. And he allows, with other philoſophers, that the attributes of ſubſtance do not differ really from the ſubſtance itſelf. He muſt, therefore, allow, that extenſion in general is ſubſtance; whence it will follow, that every part of extenſion is a particular ſubſtance; which overturns the whole ſyſtem.

2. If it be abſurd to make God extended, as this robs him of his ſimplicity, and makes him be compoſed of parts, it is ſtill worſe to reduce him to the condition of matter, the loweſt of all beings, and that which moſt of the ancient philoſophers ranked immediately above nothing; matter, the theatre of all ſorts of changes, the field of battle of contrary cauſes, the ſubject of all corruptions and generations; in a word, the being, of all others, moſt incompatible with the immutability of the Deity.

The Spinoziſts, indeed, maintain, that it is not ſuſceptible of any diviſion; but the argument they allege in proof of it we have elſewhere ſhewn to be falſe: it is, that for matter to be divided, it is neceſſary that one of the parts be ſeparated from the other by a void ſpace, which is impoſſible; ſince, they ſay, there is no vacuum in nature. See VACUUM.

3. If Spinoziſm appear extravagant, when we conſider God as the ſubject of all the mutations, corruptions, and generations, in bodies, it will be found ſtill worſe, when we conſider him as the ſubject of all the modifications of thinking. It is no ſmall difficulty to unite extenſion and thinking in the ſame ſubſtance; ſince it is not an union like that of two metals, or of water and wine, that will ſerve the purpoſe: theſe laſt require only juxta-poſition; whereas to combine thinking and extenſion, requires an identity. Thinking and extended are two attributes identified with the ſubſtance, and, conſequently, they are identified with each other by the fundamental rule of all logic.

Again, when we ſay, that a man *denies this*, *affirms that*, *likes that*, &c. we make all thoſe attributes fall on the ſubſtance of his mind, not on his thoughts, which are only accidents or modifications of it: if, therefore, what Spinoza advances be true, that men are modalities of God, it would be falſe to ſay, *Peter denies*, *likes*, *wills*, &c.; ſince, in reality, on this ſyſtem it is, that God denies, wills, &c.; and, conſequently, all the denominations which ariſe from the thoughts, deſires, &c. of men, fall properly and phyſically on the ſubſtance of God. From whence it alſo follows, that God affirms and denies, loves and hates, wills and nills the ſame thing, at the ſame time, and under the ſame conditions; contrary to the great principle of reaſoning, *oppoſita ſunt quæ & neque de ſe invicem, neque de eodem tertio ſecundum idem, ad idem, eodem modo atque tempore verè affirmari poſſunt*; which muſt be falſe, if Spinoziſm be true; ſince it cannot be denied, but ſome men love and affirm what others hate and deny, under all the conditions expreſſed in the rule.

4. But if it be phyſically abſurd to ſay, the ſame ſubject is modified at the ſame time with all the different thoughts of all men; it is horrible when we conſider it in a moral light; ſince it will follow, that the infinite, the all-perfect Being, is not conſtant, is not the ſame one moment, but is eternally poſſeſſed even with contrary paſſions: all the uniformity in him in this reſpect, will be, that for one good and wiſe thought, he will have twenty fooliſh and wicked ones. He will not only be the efficient cauſe of all the errors, iniquities, and impurities of men, but alſo the paſſive ſubject of them, the *ſubjectum inhæſionis*. He muſt be united with them in the cloſeſt manner that can be conceived, even by a penetrative union, or rather an identity, ſince the mode is not really diſtinct from the ſubſtance modified. Bayle, art. *Spinoza*.

SPINSTER, in *Law*, an addition uſually given to all unmarried women, from the viſcount's daughter downwards.

Yet ſir Edward Coke ſays, *generoſa* is a good addition for a gentlewoman; and that, if ſuch a perſon be named ſpinſter in any original writ, appeal, or inſtrument, ſhe may abate and quaſh the ſame.

Spelman ſays, that anciently, even queens uſed the diſtaff and ſpindle; whence ſpinſter became a common appellation for all women.

SPINT, in *Commerce*, a corn meaſure of Germany. At Bremen, a laſt of corn, peaſe, or beans, contains 4 quarts, 40 ſcheffels, 160 viertels, or 640 ſpints; 50 ſcheffels anſwering to 101 buſhels, Wincheſter meaſure. At Hamburgh, a laſt of wheat or rye contains 3 wiſpels, 30 ſcheffels, 60 faſſes, 120 kimterns, or 480 ſpints; and according to the ſtandard meaſure of the faſs, which is $21\frac{13}{16}$ inches in diameter, and $10\frac{3}{8}$ inches deep, Hamburgh meaſure, its contents are 3872 Hamburgh cubic inches, or 3213 Engliſh inches, 1 ſcheffel or two faſſes = 3 buſhels, Wincheſter meaſure nearly; and 1 laſt of Hamburgh = $89\frac{2}{3}$ Engliſh buſhels, or $11\frac{5}{24}$ Engliſh quarters.

SPINTHER, among the Romans, a kind of bracelet which the women, in the firſt ages of Rome, uſed to wear on the upper part of their left arm.

SPINTHERA, in *Mineralogy*, a mineral of greeniſh colour, which occurs cryſtallized in irregular dodecahedrons, compoſed of a double four-ſided pyramid, obliquely truncated at the apexes. The cryſtals are ſmall, and brightly ſhining; the fracture is lamellar. Its hardneſs is inferior to that of glaſs; it is tranſlucent on the edges. It melts before the blowpipe without much difficulty. It has not been analyſed. It was diſcovered by Haüy implanted in calcareous ſpar from Dauphiné. Aikin's Dict.

SPINUS, in the *Natural Hiſtory of the Ancients*, the name of a foſſile body of a very remarkable quality; for, according to the accounts of Theophraſtus, and other authors of the greateſt credit, it broke to pieces, and thrown in a heap expoſed to the ſun, it took fire and burnt, and that the more if moiſtened or ſprinkled with water.

It ſeems to have been a ſubſtance nearly allied to what they call the *lapis thracius*, but with this remarkable quality, both of them ſeem to have been of the claſs of the harder bitumens, and are wholly unknown to us. Some late writers have imagined, that the common black ſlate-ſtone, ſo frequent with us in the coal-pits, was the ſubſtance called by Theophraſtus, and the ancients, by this name; but it had none of the qualities attributed to the ſpinus. Hill's Theophraſtus, p. 35.

SPINUS, in *Ichthyology*, a ſpecies of the ſparus, with a bifid tail, and the dorſal ſpine recumbent. It is found in the Indian ſeas.

SPINUS, the *Fringilla ſpinus* of Linnæus, in *Ornithology*, the name of a ſmall bird, called by ſome *ligurinus*, and in Engliſh the *ſiſkin*. Its head is black, and its neck and back green; the neck, however, has ſome ſlight admixture of a blackiſh tinge, and the roots of the back feathers have alſo ſome blackiſhneſs; its rump is of a greeniſh-yellow, as are alſo its breaſt and throat; its belly is white, and its tail is yellow underneath, with ſome browniſh ſpots; the female is paler coloured than the male; and its throat, and its ſides, under the wings, are whitiſh, with ſtreaks of brown; the head and back are of a greeniſh aſh-colour, marked with brown. It is common in Germany and England, which it viſits at uncertain times, and is kept in cages for ſinging. In winter theſe birds fly in large flocks. In Suſſex it is called the barley-bird, becauſe it comes to them in the barley-ſeed time.

SPIO, in *Natural Hiſtory*, a genus of the claſs Vermes, and order Molluſca. The generic character is as follows: Body projecting from a tube, jointed, and furniſhed with dorſal fibres; peduncles or feet rough with briſtles, and placed towards the back; two feelers, which are long and ſimple; it has two oblong eyes. There are only two

Species.

* SETICORNIS. Feelers thin and ſtriate. This ſpecies inhabits the ocean, principally where there is a clayey bottom; it is about three inches long; the tube is compoſed of agglutinated particles of earth, thin, erect, and thrice as long as the body. From this the animal projects its capillary white feelers in ſearch of food, which conſiſts of ſmall marine worms; the body is whitiſh, with a tinge of green, with a red line down the middle of the back; the hind-part is of a ſea-green; the fore-part is blackiſh-grey, with tranſverſe white ſtriæ; the head is pale.

FILICORNIS. Feelers thick and annulate. It inhabits the ſea-ſhores about Greenland, and is an inch long. Body oblong, yellowiſh or reddiſh, with a cinereous line in the middle, and at each end; the tube is fragile, erect, and greeniſh, from which it projects its feelers in ſearch of *planariæ*, and other ſmall marine worms.

SPIPOLA, in *Ornithology*, the name of a ſmall bird of the lark kind, of which there are, according to Aldrovand, three ſpecies, ſuſpected by Mr. Ray to be only varieties of the *ſpinoletta*, or *tordino* of the Venetians.

Linnæus makes two of theſe diſtinct ſpecies, under the titles of *alauda trivialis*, and *alauda pratenſis*; the laſt of which is our tit-lark.

SPIRACLE. See VENT.

SPIRACULA, in the *Hiſtory of Inſects*, are little holes or pores placed ſingly on each ſide of every ſegment of the abdomen, through which the inſect breathes; and if oil be applied ſo as to ſtop them up, it proves fatal to moſt of them.

SPIRÆA, in *Botany*, a name borrowed from Theophraſtus, whoſe *σπειραια* is ſuppoſed to be one of the ſpecies of this pretty genus.—Linn. Gen. 253. Schreb. 341. Willd. Sp. Pl. v. 2. 1055. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 535. Ait. Hort. Kew. v. 3. 254. Purſh 341. Juſſ. 339. Lamarck Illuſtr. t. 439. Gærtn. t. 69.—Claſs and order, *Icoſandria Pentagynia*. Nat. Ord. *Pomaceæ*, Linn. *Roſaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, flat at the baſe, in five acute ſegments, permanent. *Cor.* Petals five, roundiſh-oblong, inſerted into the calyx. *Stam.* Filaments more than twenty, thread-ſhaped, inſerted into the calyx, ſhorter than the corolla; anthers roundiſh. *Piſt.* Germens five or more; ſtyles as many, thread-ſhaped, the length of the ſtamens; ſtigmas capitate. *Peric.* Capſules oblong, compreſſed, pointed, each of one cell and two valves. *Seeds* few, pointed, ſmall, inſerted into the inner margins of the valves.

Obſ. *S. Filipendula* and *Ulmaria* have numerous germens and capſules; *S. Aruncus* is dioecious; *S. opulifolia* has only three germens and ſtyles.

Eſſ. Ch. Calyx five-cleft. Petals five. Capſules ſuperior, of two valves, with ſeveral ſeeds.

Sect. 1. *Stem ſhrubby.*

1. S. *lævigata*. Smooth-leaved Spiræa. Linn. Mant. 244. Willd. n. 1. Ait. n. 1. (S. altaica; Pall. Roſſ. v. 1. p. 1. 37. t. 23.)—Leaves obovato-lanceolate, entire, ſeſſile, ſmooth. Cluſters ſtalked, corymboſe.—Native of Siberia. The Engliſh gardens are obliged to Dr. Solander for this ſhrub, which is quite hardy, flowering copiouſly in ſummer, and diſtinguiſhed by its very ſmooth, willow-like, rather glaucous *leaves*. *Flowers* pure white, in cluſters, collected into corymboſe tufts at the ends of the branches. The *leaves* are deciduous in all the ſpecies.

2. S. *ſalicifolia*. Willow-leaved Spiræa. Linn. Sp. Pl. 700. Fl. Brit. n. 1. Engl. Bot. t. 1468. Ait. n. 2. Purſh n. 1. Pall. Roſſ. v. 1. p. 1. 36. t. 21, 22. (S. Theophraſti fortè; Ger. Em. 1601.)—Leaves ovato-lanceolate, bluntiſh, ſerrated, ſmooth. Cluſters terminal, compound.—Native of mountain thickets, near water, in Siberia, Tartary, and North America, as well as in Scotland and the north of England. It is common in ſhrubberies, flowering in July. The *ſtem* is four or five feet high, erect, buſhy. *Leaves* ſtalked, from one to two inches long, various in breadth, deeply ſerrated. *Flowers* pink, with a dark red *calyx*. In America there is a white variety.

3. S. *calloſa*. Callous Spiræa. Thunb. Jap. 209. Willd. n. 3. (S. japonica; Linn. Suppl. 262.)—Leaves lanceolate, acute, ſerrated, rather villous. Stem downy. Panicle doubly compound, ſomewhat level-topped.—Native of Japan, flowering in June. *Leaves* longer and more acute than

than in the laſt, more villous than in the following, and not downy. The panicled *inﬂoreſcence* diſtinguiſhes it from both. *Flowers* red, on villous ſtalks.

4. S. *tomentoſa*. Scarlet Spiræa. Linn. Sp. Pl. 701. Ait. n. 3. Purſh n. 2. "Schmidt Arb. v. 1. 52. t. 51." (Ulmaria pentacarpos, &c.; Pluk. Phyt. t. 321. f. 5.)—Leaves ovate, unequally ſerrated; downy and white beneath. Cluſters compound, downy.—Native of North America; a hardy ſhrub in our gardens, flowering towards autumn, and juſtly admired for its bright red *flowers*, and the white downineſs of the backs of its *leaves*. In other reſpects it much reſembles *S. ſalicifolia*.

5. S. *argentea*. Silvery Spiræa. Linn. Suppl. 261. Willd. n. 5.—Leaves wedge-ſhaped, furrowed, ſomewhat plaited; ſilky on both ſides; ſerrated at the extremity. Cluſters compound. Capſules fringed.—Sent from New Granada by Mutis to Linnæus. The copious ſilvery *leaves*, about an inch long, render this a very elegant ſhrub. The *cluſters* are numerous at the ends of the branches, but do not conſiſt of many *flowers*. The *germens* and *capſules* are bordered with long hairs.

6. S. *alpina*. Alpine Small-leaved Spiræa. Pall. Roſſ. v. 1. p. 1. 35. t. 20. Willd. n. 6.—Leaves linear-lanceolate, partly toothed, very ſmooth. Flowers corymboſe.—Native of cold woody mountains in Siberia, near the lake Baical. A ſmall, ſpreading, branching *ſhrub*, whoſe bark ſplits into long threads. The *leaves* are hardly an inch long, and very narrow. *Flowers* white, in ſmall downy *corymbs*, ſolitary at the end of each branch.

7. S. *hypericifolia*. St. John's-wort Spiræa, or Italian May; commonly called *Hypericum frutex*. Linn. Sp. Pl. 701. Ait. n. 4. Purſh n. 3. "Schmidt Arb. v. 1. 55. t. 56." Bocc. Muſ. 137. t. 96. (Pruno ſylveſtri affinis canadenſis; Pluk. Phyt. t. 218. f. 5.)—Leaves obovate, entire. Umbels ſeſſile.—In dry ſwamps of Canada and New York, flowering in May. *Purſh*. This ſhrub, cultivated for near 200 years paſt in our Engliſh gardens, and aſſerted to be of American origin, is no leſs apparently wild on all the hills of Umbria, between Terni and Trevi, as Boccone long ago mentioned. (See Sm. Tour, ed. 2. v. 2. 322.) It is frequently called in England Italian May. The *leaves* are an inch long, reſembling ſome ſpecies of *Hypericum*. *Flowers* white, copious and very pretty, in ſmooth lateral umbels.

8. S. *chamædrifolia*. Germander-leaved Spiræa Linn. Sp. Pl. 701. Ait. n. 5. Purſh n. 4. Pall. Roſſ. v. 1. p. 1. 32. t. 15.—Leaves obovate, ſmooth, cut, and ſerrated. Corymbs ſtalked.—Native of Siberia and Hungary. Hardy with us, flowering in June and July. The *leaves* are green, or ſlightly glaucous, on both ſides, an inch, or rather more, in length. *Flowers* white, rather bigger than the laſt, nearly umbellate. *Branches* angular.

9. S. *ulmifolia*. Elm-leaved Spiræa. Scop. Carn. v. 1. 349. t. 22*. Willd. n. 9. Ait. n. 6. (S. chamædrifolia; Jacq. Hort. Vind. v. 2. 66. t. 140.)—Leaves ovate, ſmooth, doubly ſerrated; glaucous beneath. Corymbs racemoſe, elongated, on long ſtalks.—Native of Carniola and Siberia. Cultivated for about 30 years paſt in our gardens, flowering in June. A ſhrub larger in all its parts than the foregoing, eſpecially the *flowers*, which are rather racemoſe than corymboſe. The *leaves* are an inch and a half long, on ſtalks one-third that length.

10. S. *betulifolia*. Birch-leaved Spiræa. Pall. Roſſ. v. 1. p. 1. 33. t. 16. Purſh n. 5.—Leaves broadly ovate, ſmooth, deeply ſerrated, on ſhort ſtalks. Corymbs compound, level-topped.—Native of Siberia; and, according to Mr. Purſh, of the mountains of Virginia, flowering from May to July. He deſcribes it as not above a foot high; the *flowers* tinged with red, and aſſerts it to be very diſtinct from the laſt, to which Willdenow refers Pallas's ſynonym. The *leaves* appear to be much broader than in the *ulmifolia*, with ſhorter thicker *footſtalks*, and the *inﬂoreſcence* more compact.

11. S. *crenata*. Hawthorn-leaved Spiræa. Linn. Sp. Pl. 701. Ait. n. 7. Pall. Roſſ. v. 1. p. 1. 35. t. 19. (Oxyacantha anguſtifolia non ſpinoſa; Barrel. Ic. t. 564.)—Leaves obovate, acute; toothed at the extremity. Corymbs lateral, crowded, ſtalked.—Native of Siberia, Tartary, Hungary, and Spain. Cultivated by Miller in 1739, and frequently met with in curious ſhrubberies, flowering in May. The *leaves* vary much in ſize and ſhape, but are always ſtrongly toothed, or jagged, at the end. When ſmall they are often three-ribbed, but that character is not ſo conſtant as to make a ſpecific difference. *Flowers* white, in copious, ſhort, lateral, leafleſs cluſters. Willdenow ſuſpects the Spaniſh variety may be a diſtinct ſpecies, but we find our garden plant ſo variable, that the line of diſtinction is ſcarcely to be drawn. A compariſon of living ſpecimens muſt decide the queſtion.

12. S. *trilobata*. Three-lobed Spiræa. Linn. Mant. 2. 244. Willd. n. 11. Ait. n. 8. Pall. Roſſ. v. 1. p. 1. t. 17.—Leaves roundiſh, ſomewhat heart-ſhaped, bluntly lobed, toothed. Umbels terminal.—Native of mountains in Siberia. A hardy ſhrub with us, introduced by ſir J. Banks in 1801, but not yet come into general culture. It flowers in May. The *leaves* are ſmooth, not unlike thoſe of a gooſeberry in ſhape. *Flowers* white, copious, and handſome.

13. S. *thalictroides*. Meadow-rue-leaved Spiræa. Willd. n. 12. Ait. n. 9. Pall. Roſſ. v. 1. p. 1. 34. t. 18.—Leaves obovate, obtuſe, ſomewhat three-lobed. Umbels lateral, ſeſſile.—Native of the alps of Dauria. Flowering at Kew in May. A pretty ſpecies, with ſmall *leaves*, very glaucous beneath. *Flowers* white, ſmaller than the laſt, and lateral, not terminal.

14. S. *opulifolia*. Virginian Guelder-roſe. Linn. Sp. Pl. 702. Ait. n. 10. Purſh n. 6. "Schmidt Arb. v. 1. 52. t. 52." (Euonymus virginiana, ribeſii folio, capſulis eleganter bullatis; Comm. Hort. v. 1. 169. t. 87.)—Leaves ovate, three-lobed, ſerrated, ſmooth. Corymbs terminal, denſe, bracteated. Capſules poliſhed, inflated.—On the banks of rivers, particularly among the mountains, from Canada to Carolina, flowering in June and July. Generally known by the name of Nine-bark. *Purſh*. Cultivated by biſhop Compton, and now common in ſhrubberies, forming a ſmall tree, with much reſemblance to the Common Guelder-roſe. *Flowers* white, ſomewhat like Hawthorn. *Capſules* tumid, ſmooth, of a ſhining brown. *Calyx* more or leſs downy.

15. S. *capitata*. Capitate Spiræa. Purſh n. 7.—"Leaves ovate, ſomewhat lobed, doubly toothed; reticulated and downy beneath. Corymbs terminal, denſe, ſomewhat capitate, on very long ſtalks. Calyx downy."—Found by Mr. Menzies, on the north-weſt coaſt of America, flowering in June. Gathered alſo on the Columbia river by governor Lewis. *Purſh*.

16. S. *ariæfolia*. Beam-tree-leaved Spiræa.—Leaves elliptic-oblong, ſomewhat lobed, toothed; pale and villous beneath. Cluſters compound, panicled, terminal, downy.—Gathered on the north-weſt coaſt of America, by Mr. Menzies, to whom we are obliged for ſpecimens. It ſeems not noticed by Mr. Purſh. Perhaps this ſpecies ought, on account of its panicled very compound *inﬂoreſcence*, to be ranged near *ſalicifolia* and *tomentoſa*. The *leaves* are lobed

like *Pyrus Aria*, but rather ſmaller, and villous, not cottony, beneath. The dried *flowers* look as if they had been reddiſh.

17. S. *diſcolor*. Folded-leaved Spiræa. Purſh n. 8.—"Leaves ovate, lobed, toothed, ſomewhat plaited; ſnow-white and downy beneath. Panicles terminal, ſtalked, very much branched."—On the banks of the Kooſkooſky, gathered by governor Lewis, flowering in June and July. A ſhrub about five feet high. *Purſh*. Can this be the ſame ſpecies with our laſt? We have not had an opportunity of comparing ſpecimens.

18. S. *ſorbifolia*. Service-tree-leaved Spiræa. Linn. Sp. Pl. 702. Ait. n. 11. Purſh n. 9. Pall. Roſſ. v. 1. p. 1. 34. t. 24, 25. (S. n. 51; Gmel. Sib. v. 3. 190. t. 40.)—Leaves pinnate; leaflets uniform, ſharply ſerrated. Stem ſhrubby. Flowers panicled.—Native of Siberia and the north-weſt coaſt of America, flowering in July and Auguſt. Frequent in gardens, and diſtinguiſhed by the elegance of its bright-green, finely ſerrated *leaves*, as well as its large panicles of cream-coloured *flowers*. The *root* creeps in ſome degree. The *ſtems* are three or four feet high, not very woody.

Sect. 2. *Stem herbaceous.*

19. S. *Aruncus*. Goat's-beard Spiræa. Linn. Sp. Pl. 702. Ait. n. 12. Purſh n. 10. Pall. Roſſ. v. 1. p. 1. 39. t. 26. (Barba capri; Fuchſ. Hiſt. 181. B. capræ; Camer. Hort. 26. t. 9.)—Leaves doubly compound. Spikes panicled. Flowers dioecious.—Native of Siberia, Auſtria, Switzerland, the Pyrenées, and the mountains of North America. A hardy perennial in our gardens, of great elegance, about a yard high, with ample light-green *leaves*, and innumerable white feathery *flowers*, produced in June and July.

20. S. *Filipendula*. Common Dropwort Spiræa. Linn. Sp. Pl. 702. Willd. n. 16. Fl. Brit. n. 2. Engl. Bot. t. 284. Fl. Dan. t. 635. (Filipendula; Ger. Em. 1058. Camer. Epit. 608. Matth. Valgr. v. 2. 217.)—Leaves interruptedly pinnate; leaflets uniform, ſerrated, ſmooth. Stem herbaceous. Flowers cymoſe, with many ſtyles.—Native of high chalky or gravelly paſtures in England, and other parts of Europe, flowering in July. Commonly double in gardens. The *root* is perennial, furniſhed with oval woody knobs. *Stem* one or two feet high. *Leaflets* ſmall, oblong, ſharply cut. *Flowers* cream-coloured, with here and there a tinge of red.

21. S. *Ulmaria*. Meadow-ſweet Spiræa. Linn. Sp. Pl. 702. Willd. n. 17. Fl. Brit. n. 3. Engl. Bot. t. 960. Curt. Lond. faſc. 5. t. 33. Fl. Dan. t. 547. (Regina prati; Ger. Em. 1043.)—Leaves interruptedly pinnate; downy beneath: the terminal leaflet lobed. Flowers cymoſe, with many ſtyles.—Common in wet meadows, bogs, and the borders of rivers and pools throughout Europe, flowering in June and July. The *root* is fibrous, perennial. *Stems* three or four feet high. *Leaves* broad, ſerrated; white underneath. *Flowers* cream-coloured, copious, with a very ſweet, but oppreſſive, fragrance. *Germens* twiſted.

22. S. *digitata*. Fingered Spiræa. Willd. n. 18. (S. palmata; Linn. Suppl. 262. Pall. Roſſ. v. 1. p. 1. 40. t. 27.)—Leaves pinnate; downy beneath: the terminal leaflet largeſt, in ſeven deep lobes; ſide ones in five. Corymb compound, denſe.—Native of moiſt mountainous ſituations, in the eaſtern part of Siberia. This has the habit of the laſt, but the palmate deeply divided *leaflets* abundantly diſtinguiſh it.

23. S. *lobata*. Palmate Red Spiræa. Jacq. Hort. Vind. v. 1. 38. t. 88. Willd. n. 19. Purſh n. 11.—Leaves pinnate, ſmooth: the terminal leaflet largeſt, ſeven-lobed: ſide ones three-lobed. Corymbs proliferous.—In fertile wet meadows of Virginia and Carolina, flowering in July and Auguſt. A beautiful perennial; *flowers* red, in large cluſters. *Purſh*. The Linnæan herbarium ſhews that authors have here miſapplied the reference to the *Supplementum*, which belongs to the laſt ſpecies.

24. S. *camtſchatica*. Broad-leaved Siberian Spiræa. Pall. Roſſ. v. 1. p. 1. 41. t. 28. Willd. n. 20.—Leaves five-lobed, with auricles on the ſtalks. Corymbs proliferous. Stem ſomewhat hairy.—Native of Camtſchatka and Beering's iſland. The *root* is perennial. *Leaves* very broad, ſmooth, with acute lobes. *Flowers* white.

25. S. *palmata*. Palmate Japan Spiræa. Thunb. Jap. 212. Willd. n. 21.—"Leaves palmate, ſerrated. Panicle repeatedly compound. Stem ſmooth."—Native of Japan. The ſtalks of the *leaves* ſeem to have no auricles, and the *ſtem* is ſmooth; otherwiſe the deſcription of this ſpecies bears ſome reſemblance to the laſt. *Flowers* red or white.

26. S. *trifoliata*. Common Three-leaved Spiræa. Linn. Sp. Pl. 702. Ait. n. 16. Purſh n. 12. Curt. Mag. t. 489.—Leaves ternate, ſerrated, nearly equal. Stipulas linear. Flowers terminal, looſely panicled. Calyx tubular.—In ſhady woods and on bogs, chiefly in the mountainous parts of North America from Canada to Florida, flowering in June and July. *Purſh*. A hardy perennial in our gardens, of ſingular elegance, with large drooping *flowers*, whoſe *petals* are white, *calyx* deep red.

27. S. *ſtipulacea*. Auricled Three-leaved Spiræa. Willd. Enum. 542. Purſh n. 13.—Leaves ternate, ſerrated, nearly equal. Stipulas ovate, leafy, cut. Flowers terminal, looſely panicled. Calyx bell-ſhaped.—In the ſhady woods of Kentucky and Tenaſſee, flowering in June and July. *Purſh*. We received it from the choice garden of James Vere, eſq. in Auguſt, 1814. The general appearance of this ſpecies is very like the laſt, but the very large *ſtipulas*, and perhaps the ſhorter greener *calyx*, diſtinguiſh it.

SPIRÆA, in *Gardening*, contains plants of the ſhrubby and herbaceous kinds, among which the ſpecies cultivated are, the willow-leaved ſpiræa (S. ſalicifolia); the ſcarlet-leaved ſpiræa (S. tomentoſa); the hypericum-leaved ſpiræa (S. hypericifolia); the ſilver-leaved ſpiræa (S. argentea); the germander-leaved ſpiræa (S. chamædrifolia); the hawthorn-leaved ſpiræa (S. crenata); the three-lobe-leaved ſpiræa (S. triloba); the currant-leaved ſpiræa (S. opulifolia); the ſervice-leaved ſpiræa (S. ſorbifolia); the goat's-beard ſpiræa (S. aruncus); the common dropwort ſpiræa (S. filipendula); the common meadow-ſweet ſpiræa (S. ulmaria); and the three-leaved ſpiræa (S. trifoliata).

In the firſt ſpecies there are ſeveral varieties; as the fleſh-coloured willow-leaved, the Alpine willow-leaved, the panicled willow-leaved, and the broad willow-leaved ſpirææ. The tough, ſtraight, pliant, young ſhoots of this plant are ſometimes uſed to top fiſhing-rods, &c.

The fifth ſpecies varies very much, with larger or ſmaller leaves, more or leſs cut, but more commonly quite entire and ovate-acute.

The eighth ſort is commonly known in the nurſeries by the name of Virginian guelder roſe.

The eleventh ſort is an elegant plant, which in gardens grows very luxuriantly, and has often double flowers.

In the twelfth ſort there are varieties with double flowers, and with variegated leaves.

Method of Culture.—In all the ſhrubby ſorts, this may be performed by ſuckers, layers, and cuttings. The ſuckers ſhould be taken off in the autumn, and planted out where they are to remain, or in nurſery-rows, to attain a fuller growth. The firſt ſort requires to be cleared of theſe ſuckers every two years at fartheſt. The layers ſhould be put down in the autumn, or in the ſpring, and may be taken off and planted as above, in the autumn or ſpring following. All the ſorts may be raiſed in this way; but it is moſt proper for ſuch ſorts as do not ſend off ſuckers. The cuttings may be made from the ſhoots of the preceding ſummer, and be planted out in a ſhady border, in the early autumn. When they have become well rooted, they may be removed, and managed as the others. They ſucceed in this way with more difficulty than in either of the others.

All the herbaceous ſorts may be increaſed by ſeeds, or parting the roots. The ſeed may be ſown in the autumn, or early in the ſpring, but the firſt is the better mode, on a bed of fine mould. When the plants appear, they ſhould be kept clear from weeds till the autumn, when they may be planted where they are to remain, or in the nurſery for a year or two. The roots ſhould be parted in the autumn or ſpring, when the ſtems decay, before they ſhoot out new ones, being planted immediately where they are to grow. The double-flowered and ſtriped varieties can only be preſerved in this way.

They all afford variety and ornament in the ſhrubbery, and other parts of pleaſure-grounds.

Spiræa, *African*, in *Botany*. See Diosma.

SPIRAL, in *Geometry*, a curve line of the circular kind, which, in its progreſs, recedes from its centre; as in winding from the vertex, down to the baſe of a cone.

It is called, from its inventor, *Archimedes's ſpire*, or *helix*, and is thus deſcribed: divide the periphery of a circle A P *p* A (*Plate* XIV. *Geometry*, *fig*. 4.) into any number of equal parts, by a continual biſection in the points *p*. Into the ſame number of parts divide the radius C A, and make C M equal to one part, C *m* to two parts, &c. Then will the points, M, *m*, *m*, &c. be points in the ſpiral; which, connected, will give the ſpiral itſelf.

This is more particularly called the *firſt* ſpiral; and the ſpace included between its centre and the point A, the ſpiral *ſpace*.

The firſt ſpiral may be continued to a *ſecond* ſpiral, by deſcribing another circle with double the radius of the firſt; and the ſecond may be continued to a *third*, by a third circle, &c.

Hence, 1. Ap is to the periphery, as Cm to the radius: wherefore, if the periphery be called p, the radius $AC = r$, $Ap = x$, $pm = y$; then will $Cm = r - y$: conſequently, as $p : r :: x : r - y$, we ſhall have $pr - py = rx$.

2. If $Cm = y$, then will $rx = py$; which equation the ſpiral has in common with the quadratrix of Dinoſtrates, and that of Tſchirnhauſen: and, therefore, $r^n x^m = p^n y^m$ will ſerve for infinite ſpirals and quadratrices. See Quadratrix.

The ſpiral line may be conceived to be thus generated: If a right line, as A B (*Plate* XIV. *Geometry*, *fig*. 5.) having one end fixed at B, be equally moved round, ſo as, with the other end A, to deſcribe the periphery of a circle; and, at the ſame time, a point be conceived to move forward equally, from B towards A, in the right line A B, ſo as that the point deſcribes that line, while the line generates the circle; then will the point, with its two motions, deſcribe the curve B, 1, 2, 3, 4, 5, &c. which is called a ſpiral line; and the plain ſpace contained between the ſpiral line and the right line B A, is called the ſpiral ſpace.

Again, if the point B be conceived to move twice as ſlow as the line A B, ſo that it ſhall get but half way along B A, when that line ſhall have formed the circle; and if then you imagine a new revolution to be made of the line carrying the point, ſo that they ſhall end their motion at laſt together, there will be formed a double ſpiral line, as in the figure: from the manner of which may be eaſily drawn theſe corollaries:

1. That the lines B 12, B 11, B 10, &c. making equal angles with the firſt and ſecond ſpiral (as alſo B 12, B 10, B 8, &c.) are in arithmetical proportion.

2. The lines B 7, B 10, &c. drawn any how to the firſt ſpiral, are to one another as the arcs of the circle intercepted betwixt B A and thoſe lines; becauſe, whatever parts of the circumference the point A deſcribes, as ſuppoſe 7, the point B will alſo have run over 7 parts of the line A B.

3. Any lines drawn from B to the ſecond ſpiral, as B 18, B 22, &c. are to each other as the aforeſaid arcs, together with the whole periphery added on both ſides: for at the ſame time that the point A runs over 12, or the whole periphery, or perhaps 7 parts more, ſhall the point B have run over 12, and 7 parts of the line A B, which is now ſuppoſed to be divided into 24 equal parts.

The area C A B D E of the ſpiral of Archimedes (*Plate* XIV. *Geometry*, *fig*. 6.) is equal to one-third part of the circle, deſcribed with the radius C E.

In like manner, the whole ſpiral area, generated by the ray drawn from the point C to the curve, when it makes two revolutions, is the third part of a ſpace double of the circle deſcribed with the radius 2 C D; and the whole area, generated by the ray from the beginning of the motion, till after any number of revolutions, is equal to the third part of a ſpace that is the ſame multiple of the circle deſcribed with the greateſt ray, as the number of revolutions is of unit.

Any portion of the area of the ſpiral, terminated by the curve C *m* A, and the right line C A, is equal to one-third of the ſector C A G, terminated by the right lines C A and C G, the ſituation of the revolving ray, when the point that deſcribes the curve ſets out from C. See Maclaurin's Fluxions, Introd. p. 30, 31. See Quadrature *of the Spiral of Archimedes*.

Spiral, *Logiſtic*, or *Logarithmic*. See Logistic and Quadrature.

Spiral *of Pappus*, a ſpiral formed on the ſurface of a ſphere, by a motion analogous to that by which the ſpiral of Archimedes is deſcribed in plano.

This ſpiral is ſo called from its inventor Pappus. Collect. Mathem. lib. ii. prop. 30.

Thus, if C be the centre of the ſphere (*fig*. 7.), A R B A a great circle, P its pole; and while the quadrant P M A revolves about the pole P with an uniform motion, if a point proceeding from P move with a given velocity along the quadrant, it will trace upon the ſpherical ſurface the ſpiral P F *a*.

Now if we ſuppoſe the quadrant P M A to make a complete revolution in the ſame time that the point, which traces the ſpiral on the ſurface of the ſphere, deſcribes the quadrant, which is the caſe conſidered by Pappus; then the portion of the ſpherical ſurface terminated by the whole ſpiral, the circle A R B A, and the quadrant P M A, will be equal to the ſquare of A B. In any other caſe, the area P M A *a* F Z P is to the ſquare of the diameter A B, in the ſame proportion as the arc A *a* is to the whole circumference A R B A. And this area is always to the ſpherical triangle P A *a*, as the inſcribed ſquare is to the circle. See Maclaurin's Fluxions, Introd. p. 31—33.

The portion of the ſpherical ſurface, terminated by the quadrant P M A, the arcs A R, F R, and the ſpiral P Z F, admits of a perfect quadrature, when the ratio of the arc A *a* to

A *a* to the whole circumference can be aſſigned. See Maclaurin, ibid. p. 33.

SPIRAL, *Parabolic.* See HELICOID.

SPIRAL, *Proportional,* is generated by ſuppoſing the radius to revolve equably, and a point from the circumference to move towards the centre with a motion decreaſing in a geometric progreſſion. See LOGISTIC.

From the nature of a decreaſing geometric progreſſion, it is eaſy to conceive that the radius C A (*fig.* 8.) may be continually divided; and although each ſucceſſive diviſion becomes ſhorter than the next preceding one, yet there muſt be an indefinite number of diviſions or terms before the laſt of them becomes of no finite magnitude. Whence it follows, that this ſpiral winds continually round the centre, and does not fall into it till after an indefinite number of revolutions: and alſo that the number of revolutions decreaſes, or the number of the equal parts into which the circumference is divided increaſes.

It is alſo evident, that any proportional ſpiral cuts the intercepted radii at equal angles: for, if the diviſions A *d*, *de*, *ef*, *fg*, &c. of the circumference be very ſmall, the ſeveral radii would be ſo cloſe to one another, that the intercepted parts A D, D E, E F, F G, &c. of the ſpiral might be taken as right lines; and the triangles C A D, C D E, C E F, &c. would be ſimilar, having equal angles at the point C, and the ſides about thoſe angles proportional: conſequently, the angles at A, D, E, F, &c. being equal, the ſpiral muſt neceſſarily cut the radii at equal angles. Robertſon's Elem. of Nav. book ii. p. 87.

Proportional ſpirals are ſuch ſpiral lines as the rhumb lines on the terreſtrial globe, which, becauſe they make equal angles with every meridian, muſt alſo make equal angles with the meridians in the ſtereographic projection on the plane of the equator, and therefore will be, as Dr. Halley obſerves, proportional ſpirals about the polar point. From whence he demonſtrates, that the meridian line is a ſcale of log. tangents of the half meridian complements of the latitudes. See RHUMB, LOXODROMY, and MERIDIONAL *Parts.*

SPIRAL, in *Architecture* and *Sculpture,* denotes a curve that aſcends, winding about a cone, or ſpire, ſo that all the points of it continually approach the axis.

By this it is diſtinguiſhed from the helix, which winds, after the ſame manner, around a cylinder. Ignorant architects confound the two, but the more knowing diſtinguiſh them carefully.

SPIRAL *Pump.* See *Archimedes's* SCREW.

SPIRAL *Stairs,* in *Building.* See STAIRS.

SPIRAL *Veſſels,* in *Vegetable Phyſiology,* are found ranged concentrically round the pith in the tender branches or ſtalks of numerous plants, particularly the Elder, Syringa, Cornel, Peony, and many of the Liliaceous order. If a branch be partly cut tranſverſely, or gently broken, and the portions ſlowly drawn aſunder, a number of fine white fibres will be perceived gradually to unroll, and theſe will often ſupport a conſiderable piece of the divided ſtalk. Theſe fibres originally formed the coat of the veſſels in queſtion. After the plant has acquired a certain firmneſs of texture, or has finiſhed its growth for the ſeaſon, ſuch can no longer be unrolled. Mirbel has delineated many ſpecimens of theſe veſſels, in which the ſpiral fibre of each is more or leſs imperfect, ſhewing that, probably as they advance in age, the veſſels become entire tubes.

The uſe of theſe ſpiral-coated veſſels has been much diſputed. They being commonly found on diſſection to contain ſcarcely any fluid but air, Malpighi, Grew, and others, have called them air-veſſels, ſuppoſing they were the lungs of plants, and imbibed air from the atmoſphere, through another more external ſet of roundiſh or oval air-veſſels, of which leaves, petals, &c. are full. But the experiments of Darwin and Knight rather ſhew the ſpiral-coated tubes to be the true ſap-veſſels, in which light we have conſidered them in the article CIRCULATION *of Sap,* to which we refer the reader. No ſuch ſpiral veſſels are found in the bark of plants, at any period of its growth.

SPIRATION. See EXPIRATION, INSPIRATION, PERSPIRATION, RESPIRATION, and TRANSPIRATION.

SPIRATION, in *Scholaſtic Theology,* a term uſed by the popiſh ſchoolmen to ſignify the manner in which the perſonality of the Holy Spirit was derived from the Father and the Son. See PROCESSION and *Holy* SPIRIT.

SPIRDING SEE, in *Geography,* a large lake of Pruſſia; 30 miles S. of Bartenſtein.

SPIRE, in *Agriculture,* a term ſignifying to ſprout, as grain in the malting proceſs, &c. The ſpiring in this proceſs ſhould neither be carried too far nor ſtopped too ſuddenly, as in both caſes the malt ſuffers injury. See MALT.

SPIRE, *Spira,* in the *Ancient Architecture,* is ſometimes uſed for the baſe of a column, and ſometimes for the aſtragal, or tore.

The word is formed from the Latin *ſpiræ,* the *folds of a ſerpent,* which bear ſome reſemblance to it; or from the Greek σπειρα, the *coil of a rope.*

SPIRE is alſo a pyramidical termination of the tower of a church or other building. This ornament, being the genuine offspring of the pointed arch, and not occurring in the monuments of Greece or Rome, ought to be confined to its proper ſtyle. It is an incongruity to introduce it into Grecian architecture.

SPIRE, in *Geography,* a city of France, and principal place of a diſtrict, in the department of Mont Tonnerre, containing 3744 inhabitants, (its canton having 7894,) in 9 communes. This was, before the French revolution, an imperial city of Germany, and the capital of a biſhopric of the ſame name. Spire is an ancient city, ſaid to have been founded before the commencement of the Chriſtian era, and receives its name from the ſmall river Spirebach, which runs into the Rhine, about 500 paces below it. It contains a cathedral, three collegiate churches, and ſeveral convents, beſides two churches belonging to the Lutherans, of which claſs the magiſtrates and greater number of the inhabitants conſiſt. The Franks took this city from the Romans, and it became one of the original imperial cities. In the year 1529, a diet was held here, in which the reformers firſt obtained the name of Proteſtants. It was deſtroyed by the French in 1689, and lay waſte for ten years, nor was it rebuilt till after the peace of Ryſwick. Before this diſaſter, it was the ſeat of the imperial chamber. In December 1793, it ſurrendered to the republican troops of France. The biſhopric of Spire is of conſiderable antiquity. Its territories were ſituated on the Rhine, between the Palatinate, the duchy of Wurtemburg, the margraviate of Baden, and the principality of Deux-Ponts, about 18 leagues in length, and 12 in breadth. It is mountainous, and covered with foreſts; nevertheleſs it produces corn, wine, cheſnuts, and almonds. The biſhop was ſuffragan of Mentz, and reſided at Bruchſal. The territories on the left bank of the Rhine have been united to France, and in 1802, thoſe on the right were given as indemnities to the margrave of Baden; 12 miles S.W. of Heidelberg. N. lat. 49° 18′. E. long. 8° 30′.

SPIRES, in *Rural Economy*, a term provincially uſed to ſignify timber-ſtands.

SPIRINCHUS, in *Ichthyology*, a name by which ſome authors have called the ſmelt.

SPIRIT, Spiritus, in *Phyſiology*, the moſt ſubtle and volatile part, or juice of the body; by means of which its functions and operations have been ſuppoſed to be performed.

The ancients made a fourfold diviſion of ſpirits; into *vital, animal, natural,* and *genital;* the firſt of which they placed in the heart; the ſecond, in the brain; the third, in the ſtomach and liver; and the laſt, in the teſticles: but as this diviſion is founded on a falſe hypotheſis, it is now deſervedly ſet aſide.

The moderns have uſually divided ſpirits into *vital* and *animal:* the former being only the fineſt and moſt agitated parts of the blood, on which its motion and heat depend: and the latter an exceedingly thin, ſubtle, moveable fluid, juice, or humour, ſeparated from the blood in the cortex of the brain, and thence received into the minute fibres of the medulla, and by them diſcharged into the nerves; by which it is conveyed through every part of the body, to be the inſtrument of ſenſation, muſcular motion, &c. See Animal *Spirits,* and Nervous *Fluid, Juice,* and *Syſtem.*

Spirits, *Low,* in *Medicine.* See Melancholy.

Spirit, *Spiritus,* in the *Newtonian Phyſics,* denotes a moſt ſubtle penetrative ſubſtance, which ſome have ſuppoſed to pervade all, even the denſeſt bodies, and to lie hid in them; and by the force and action of which, the particles of bodies attract each other, at very ſmall diſtances, and, when contiguous, cohere; and by which electrical bodies act at greater diſtances, both attracting and repelling the neighbouring corpuſcles; and light is emitted, reflected, and inflected, and warms bodies; and all ſenſation is excited, and the members of the animals move at the inſtance of the will, *viz.* by vibrations of this ſpirit, propagated through the ſolid capillaments of the nerves, from the external organs of ſenſe to the brain, and from the brain to the muſcles.

Spirit, in *Antiquated Chemiſtry,* is one of the hypothetical principles of natural bodies, called alſo *mercury.*

The chemical principle ſpirit was defined to be a fine, ſubtle, volatile, penetrating, pungent liquor, which riſes, ordinarily, before the phlegm, or water, and ſometimes after it.

The great properties of this liquor were imagined to be, that it penetrates and opens ſolid bodies; corrodes, breaks, and even diſſolves certain mixed bodies; coagulates others; and produces an infinity of other effects, many of them even contrary to one another.

In the general, the early chemiſts gave the denomination of ſpirits to all the fine, ſubtle, not aqueous, particles raiſed from bodies by heat, and reduced into liquors by diſtillation. Such are ſpirit of vitriol, of nitre, of ſalt, &c.

They alſo applied the name ſpirits to thoſe aqueous liquors which are drawn by liquefaction, when they are impregnated with ſalts or other active principles, raiſed, together with them, by the violence of the fire.

In this ſenſe, the chemiſts were ſaid to draw a ſpirit from ſulphur, ſalt, and other bodies, when they extract the eſſence, or the ſubtileſt part of them, by diſtillation, or otherwiſe. Accordingly, ſpirits were diſtributed into three principal kinds, *viz. inflammable* ſpirits, *acid* ſpirits, and *alkaline* ſpirits.

To the firſt claſs belong the moſt volatile and thinneſt part of eſſential oils, the principle of ſmell, or *ſpiritus rector* of plants, (ſee Aroma,) and *ardent* ſpirits, or the ſpirit obtained from wine, beer, and all liquors which have undergone the ſpirituous fermentation. See Alcohol.

The ſecond claſs includes all acids obtained by diſtillation of minerals, vegetables, and animals; ſuch are, 1. The acids of ſulphur, vitriol, and alum, which are the ſame as vitriolic acid, and the acids of nitre and common ſalt. They are called ſpirit of ſulphur, ſpirit of vitriol, ſpirit of nitre, &c. without ſpecifying that they are acids. 2. The acids of vinegar, and of all liquors which have undergone the acetous fermentation, and the acids obtained in the diſtillation of vegetables, and of certain animals, as flies, ants, &c. Theſe ſpirits are commonly called *acid* ſpirits, as the acid ſpirit of guaiacum, the acid ſpirit of ants, &c. becauſe the ſubſtances which furniſh them yield alſo ſpirits that are not acid. See Acid.

To the third claſs are referred liquid volatile alkalies, obtained from ſal ammoniac, from all vegetable matters which have undergone a complete putrefaction, and from all animal matters. Theſe are generally called ſpirits, without ſpecifying their alkaline quality. Thus we ſay, volatile ſpirit of ſal ammoniac, ſpirit of hartſhorn, &c. As ſome of theſe ſubſtances, particularly ſal ammoniac, contain alſo an acid which may be obtained from them, we ought, when we mention this ſpirit, to ſpecify its acid quality, calling it acid ſpirit of ſal ammoniac.

Spirits, *Diſtilled,* a general name given among diſtillers to thoſe ardent liquors that are obtained from various materials, and by different proceſſes of diſtillation. The nature and properties of theſe liquors, and the modes of obtaining them, are detailed under the articles Alcohol, Brandy, Distillation, Fermentation, &c.; but we ſhall here ſpecify ſome particulars that more immediately relate to the common ſpirituous liquors that are, we lament to ſay it, ſo much in uſe in our own country. Theſe are, for the moſt part, prepared from fermented corn of one kind or other, with certain additions, at the pleaſure of the diſtiller, of molaſſes, carrots, and other ſubſaccharine vegetables. The principal ingredient, except in a ſeaſon of ſcarcity, is one kind or other of grain. (See Addition.) The ſpirit thus procured is rectified for ſale by being rediſtilled with juniper-berries, turpentine, and other ſubſtances, in order to modify and improve its flavour and appearance. The grain, when barley is uſed, is uſually firſt malted, and in Scotland it is dried with peat, which gives to the ſpirit diſtilled from it, called "whiſky," its peculiar flavour. It is then ground into coarſe powder, and the infuſion fermented with yeaſt in large tuns. This fermented liquor is called "waſh," and in this ſtate it is fit for diſtillation. Under the articles already referred to, the general proceſs and the implements uſed in it are deſcribed; but previouſly to the operation ſome ſubſtances are added to the waſh, for the purpoſe either of increaſing the quantity of ſpirit that is afforded by it, or of keeping down the eſſential oil derived from the malt, which would give the liquor a nauſeous flavour, or of regulating the boiling within the ſtill, and preventing it from boiling over or "running foul," or of neutralizing the acid generated during the fermentation, which would very conſiderably leſſen the product of ſpirit. For theſe purpoſes ſoap is conſidered the beſt addition, and accordingly it is uſed in large quantities. Other diſtillers uſe alkalies. At the commencement of the operation, the liquid is oily and turbid, and has a nauſeous flavour, on account of the oil of the malt which accompanies it; but by degrees it becomes clear, and runs ſo to the laſt, although its ſtrength decreaſes, and it becomes more watery, and conſequently of leſs ſpecific gravity. (See *Specific* Gravity.) The quantity intermediately obtained, omitting the firſt and the laſt products, is then rediſtilled or "rectified," (ſee Rectification); and in this ſtage of the operation, thoſe additions (ſuch as juniper-berries, &c.) which give the ſpirit its flavour, are introduced into it. The proceſs of diſtillation on a ſmall ſcale is ſimple and eaſily conducted; but the large diſtilleries, where expenſive works are carried on, require a greater degree of practical ſkill, both in the preparation of the apparatus, the adjuſtment of the materials, and the conduct of the operation. In order to expedite the proceſs, ſeveral alterations have been made in the form of the ſtill, particularly in Scotland, where it is an object of importance to be quick in the diſpatch of the operation, on account of the mode of levying the duty; and, therefore, by gradually widening the bottom and contracting the height of the ſtill, diſtillation is performed with a ſurpriſing rapidity. A ſtill is ſaid to have been conſtructed, which contains only 40 gallons in the body and three in the head, and in the uſe of it the whole time of its operation, from its commencement to its cloſe, amounts only to $2\frac{3}{4}$ minutes, when the charge of waſh is 16 gallons, or $\frac{2}{5}$ths of the whole content. In rectification, which is a ſlower proceſs, the charge is 24 gallons, and the time of diſtilling about 10 minutes.

A good ſpirit may be obtained without malting the grain, whether it be barley, or any other kind of corn which will anſwer the purpoſe. With us, a mixture of barley and malt is generally preferred; in Holland, the very beſt geneva is made from wheat and malt, though more commonly from malt and rye, the latter yielding more ſpirit than wheat.

The following proceſs is that which is practiſed by moſt diſtillers. A quantity of rye-flour, coarſely ground, is mixed with a third or fourth part of malt, and put into the fermenting tub, with cold water, ſtirring it well with the hand, to prevent the meal from clotting. Water of a blood-warmth is then added, in ſufficient quantity, after which the ferment, compoſed of the yeaſt of former operations, dried and kept for a certain time, is mixed with the whole. (See Ferment.) When the weather is favourable, and the heat well regulated, the fermentation begins in ſix hours, and terminates on the third day, when the liquor becomes tranſparent, and aſſumes a hot pungent taſte. The diſtillation is then immediately commenced, before the liquor turns ſour, which ſhould as much as poſſible be avoided. The diſtillation is conducted very ſlowly, to prevent the impregnation of the oil of the grain with the ſpirit, and of courſe the unpleaſant flavour of the ſpirits. The firſt ſpirit is then rectified by a ſecond diſtillation over juniper-berries, or in "double geneva," by a third proceſs.

In ſome of the ordinary ſorts, however, the juniper-berries are mixed with the fermenting materials, and one diſtillation ſuffices. In the common geneva or gin, vulgarly uſed in this country, the fine juniper flavour is coarſely imitated by turpentine. See Geneva.

For the proceſs of obtaining arrack, brandy, and rum, ſee Arac, Brandy, and Rum.

Spirits, *Proof*, or *common ſaleable goods*, are ſpirits of any kind of a determinate ſtrength, being the ſame with thoſe of good brandy, and the malt and ſugar ſpirits of the diſtillery, as they are uſually ſold; containing equal quantities, or definite proportions, of rectified ſpirit and water.

The beſt proof ſpirit is that diſtilled from French wine; but for common uſe, the ſpirit drawn from molaſſes may be employed.

The common method of examining whether ſpirits have this due degree of ſtrength is this:—take a long phial, fill it half way with the common malt ſpirit, and give it a ſmart ſtroke by its bottom againſt the palm of the hand, there will then appear on the ſurface a chaplet, or crown of bubbles, which will go off again in a ſtrong manner; that is, firſt remaining a while, and then going off by degrees, without breaking into ſmaller bubbles, or ſwelling into larger.

By this experiment all the traders in ſpirits judge of the ſtrength of the goods they purchaſe; yet this is a mere fallacy and deception; for if only a little vinous or ſaccharine matter, as treacle, ſyrup, muſt, rob of fruits, or the like, be added to a quantity of highly rectified ſpirit of wine, this ſlight addition will give a brandy proof to that ſpirit. See Alcohol, Brandy, and Bead *Proof*.

Whether there be any ſecret for making weaker ſpirits ſhew this proof as well as brandies, &c. is not certainly known; but the thing is practicable, ſince arrack, which is but of half the ſtrength of brandy, gives as fair a proof this way; and if a drop or two of any eſſential oil be added to a pint of brandy, it takes off its proof, and makes it appear much weaker than it is. The true ſtrength may, however, always be known, by carefully burning away a meaſured quantity of brandy, &c. ſince if it leaves one half water it is right; if more or leſs, it is too ſtrong, or too weak.

But beſide the falſe method of judging of brandies by what is called *proof*, there is another not leſs fallacious one of judging of their goodneſs, though kept as a great ſecret in the hands of ſome dealers, and imagined a certain criterion to determine whether foreign brandies are mixed with corn ſpirits. Theſe diſtillers are provided with a certain yellow liquor, a few drops of which being poured into a glaſs of right French brandy gives it a beautiful blue colour, and, by the ſtrength and goodneſs of this colour, they judge and buy; but if common malt ſpirit be tinged with oak, it would give this colour equally with French brandy, and might be purchaſed as ſuch. This proof tincture is expeditiouſly made, by diſſolving a little green vitriol, firſt calcined to a redneſs, in a weak ſpirit of ſea-ſalt, which thus becomes a yellow liquor, a ſingle drop or two of which being added to a glaſs of any inflammable ſpirit, coloured yellow or brown with oak, or with long remaining in the caſk, will inſtantly turn it of a bright and beautiful blue.

The beſt way of judging in theſe caſes is by the noſe and palate. Dilute a quantity of brandy conſiderably with water, and you will perceive the malt taſte, if mixed with malt ſpirits; or burn a little in a ſpoon, and by the ſmell and taſte of the water it leaves, you will eaſily judge whether there be malt in it.

Proof ſpirits may be diſtinguiſhed into three kinds, *perfect proof*, *more than perfect proof*, and *leſs than perfect proof*. By *perfect proof* is uſually underſtood that crown of bubbles, before mentioned, of a certain ſize, ariſing as a head upon a ſmall quantity of a well-qualified ſpirit ſhook in a ſlender phial.

Proof more than perfect, is that in which the bubbles raiſed by ſhaking the ſpirits, are larger than thoſe on the common or perfect proof, and go off more ſuddenly; that is, according as the ſpirit is higher, or approaches more to the nature of rectified ſpirit, or, as it is uſually called, *ſpirit of wine*.

Proof leſs than perfect, is that in which the bubbles are ſmaller, and go off quicker and fainter than in perfect proof; the ſpirit in this caſe being mixed with more than its own quantity of phlegm, or being too poor for ſale.

The ſureſt method of judging of the ſtrength of ſpirits, is by the hydrometer, water-poiſe, or balance; or, 2dly, by diſtillation, or finally, by deflagration. The ſpecific gravity of totally inflammable ſpirit is ſo much leſs than that of phlegm, or common water, that it is eaſily ſenſible upon the balance; whence an exact hydrometer, well balanced and graduated, and furniſhed with a proper ſcale of weights, may be of great uſe to aſſign the proportions in which pure ſpirit and water are mixed in any given liquor. (See *Specific* GRAVITY, and HYDROMETER.) Though, perhaps, a readier way than this may be that of M. Homberg's, mentioned in the Memoirs of the Paris Academy, 1718, for determining the different gravities of different fluids, by means of a bottle with a very long and ſlender neck; which being filled to a certain height with any mixture of ſpirit, is weighed againſt the ſame bottle filled with pure water.

The moſt exact of all methods of determining the ſtrength and ſpirit is by diſtillation, rectifying it up to an alcohol, or totally inflammable ſpirit; but this, though liable to no error, is too tedious to come into common uſe. And, upon the whole, the beſt method of all others, ſeems to be that of deflagration, which M. Geoffroy has been at much pains to adjuſt and improve.

In commerce, with regard to ſpirits, it would certainly be a much better method to aboliſh ſuch uncertain proofs, and to make all the goods of the ſtrength of what we call ſpirits of wine; that is, a totally inflammable ſpirit, whoſe purity is much greater, whoſe ſtrength may always be found out with exactneſs, and whoſe bulk, ſtowage, carriage, and incumbrance, would be only half in regard to that of brandy, or proof ſpirits; and it might at all times, as occaſion called for it, be mixed into a great variety of extemporaneous liquors, and the exact degree of ſtrength would be always preciſely known.

This operation, indeed, in the common way, proves ſo tedious and expenſive, and, after all, ſo ſhort of expectation, and ſo generally unſatisfactory, that it is not to be expected that the common diſtillers, till they have fallen into a better manner of working, ſhould come into the propoſal. But if, inſtead of the common way of rectifying by the hot-ſtill, they would try the uſe of a large balneum Mariæ, made of a large rectangular boiler, and a ſet of tall conical veſſels, they will find that little fire, and little attendance, and conſequently very little expence, will, in this manner, furniſh them with ſpirits reduced at once to this ſtandard, and greatly ſuperior, in all reſpects, to the common ones of the ſame ſtrength. In this caſe there would be no need of any addition of ſalts; but the diſtiller may work more perfectly, and more expeditiouſly without them, and thus preſerve the fine eſſential vinoſity of the ſpirit, which, in the common way of working, they conſtantly loſe.

The advantage of this method would be yet greater to the apothecaries, and the makers of compound cordial waters, who want only a pure ſpirit of ſuch a ſtrength, and ſuffer greatly in the fineneſs and perfection of their commodities, by the ſpirit they are obliged to uſe having in it a fulſome and nauſeous oil of its own, which will always mix itſelf with their compoſitions, and the oils of the aromatics, &c. which they add to it. If ſpirits were brought to this ſtandard for the market, there would be no poſſibility of deceit, and no farther examination need be made of it by the buyer than its burning perfectly dry in a ſpoon. Shaw's Eſſay on Diſtillery.

It is, however, to be obſerved, that though the burning of ſpirits away in a ſpoon may ſerve the trader in the common way, yet M. Geoffroy has obſerved, that they are no proofs for the philoſopher, or the chemiſt, being not at all determinate or exact, though commonly ſuppoſed ſo.

From what has been ſaid, it appears that brandy is much more inflammable than wine, and ſpirit of wine much more ſo than brandy, and ought to burn away without leaving any remainder. Hence it is vulgarly ſuppoſed, that ſuch ſpirit of wine as burns wholly away contains no phlegm, and that if two parcels of ſpirit both burn wholly away in this manner, they muſt be the ſame in ſtrength, and in all other qualities; but M. Geoffroy has proved by experiment, that ſuch ſpirit as burns wholly away, does yet contain a great deal of water, and two parcels both may burn thus away, and yet be very different; and that this trial is not determined by the entire abſence of the phlegm, but by its proportion to the oil.

If the ſame ſpirit of wine, which in the common way of burning leaves no water, be again tried, by burning it in a hollow veſſel ſet to float in a large quantity of cold water, it will then leave a conſiderable quantity of water; nay, all that is rectified only in the common way, leaves a large portion of phlegm on this experiment. The plain reaſon of which is, that this is the only fair trial, the other in the common way being fallacious. In this there is no more water left than was in the ſpirit; but in the other, the veſſel becoming heated by the burning of the ſpirit, that heat gradually evaporates the water, as the ſpirit burns away; ſo that the one is as ſoon gone as the other. But keeping the veſſel cool by external water, prevents that evaporation, and conſequently retains and diſcovers all that cannot burn of the ſpirit.

The quantity of water thus diſcovered in ſpirit of wine is very great, and it has always been found, that in proportion as the experiment has been made more and more perfect, the ſpirit has always appeared proportionably leſs and leſs ſo.

Pure alcohol, or alcohol of a ſpecific gravity of .796, at 60° Fah., which is the ſtrongeſt that can be procured, leaves no water; rectified ſpirit of moderate ſtrength, 25 *per cent.*; French brandy, 56; and common malt liquor, 65.

The teſt for aſcertaining the ſtrength of ſpirits by pouring a few drops on gunpowder, is very incorrect. A more accurate teſt than any of theſe, and ſufficient for common purpoſes, is to ſhake the ſpirit in a phial with very dry carbonate of potaſs, and obſerve the quantity of water attracted by the alkali, which indicates its ſtrength. But the only certain mode of aſcertaining the relative ſtrength of ſpirits, is by determining the ſpecific gravity of the ſpirit at a given temperature; thus, at 60° Fahr. the ſpecific gravity of rectified ſpirit is .83599, at 65° it is .83362, and at 70° the gravity of the ſame ſpirit is .83134; while the gravity of the proof ſpirit of the London College, at the ſame degree of temperature, is .93002, .92794, and .92580, (ſee the table under SPIRITS, in the *Materia Medica*,) the weakeſt ſpirit having the greateſt ſpecific gravity, and this diminiſhing as the temperature increaſes. For ordinary purpoſes, the relative ſtrength of ſpirits may be known by weighing the ſample to be tried in a phial capable of holding exactly 500 grains of water. An equal bulk of rectified ſpirit weighs 418 grains, and of proof ſpirit 465; hence the number of grains above or below theſe ſums will indicate the relative ſtrength of the ſpirit.

The quality of the phlegm that is left is alſo of uſe to judge of the ſpirit by; if that were perfectly fine, this ought to be perfectly limpid and clear, and without taſte or ſmell: as it wants either of theſe properties, it is a proof of the want of perfection of the ſpirit it is obtained from; but the greateſt of all defects, is its having a coarſe oil ſwimming upon it, and giving the colours of the rainbow in different lights. Mem. Acad. Par. 1718. See BRANDY.

SPIRITS, *Colouring of*, the art of giving to diſtilled liquors a colour, which takes off their watery appearance, and gives them a reſemblance of the foreign brandies, &c.

The colouring is not only neceſſary on this account, but as we uſually eſteem the ſpirits by the proof of the crown of bubbles, it is found that the clean rectified ſpirit will not afford this proof till it has received its doſe of the colour. The diſtillers diſpenſe this colour in any proportion that they find convenient or neceſſary; it is always yellow, but, according to the degree, differs extremely in deepneſs, from the paleſt ſtraw-colour to the deepeſt orange. This art of colouring was firſt introduced, from obſerving that all the fine and ſoft foreign brandies, that had the mellowneſs neceſſary to their perfection to the taſte, had alſo a yellow colour. The colour, in this caſe, has indeed nothing to do with the flavour; but that being kept in caſks the ſame age that was neceſſary to give them this mellowneſs, would alſo give them a colour from the wood. It was hence ſuppoſed, that the particular excellence of the foreign brandies depended on the woody colour, and accordingly pains have been taken to give the ſame colour to our ſpirits by various methods.

The way of obtaining it, by many years ſtanding in the caſk, proved too tedious for our haſty workmen, and accordingly they provided means of giving it extempore by ſtrong tinctures of ſeveral ingredients; the chief of which are logwood, ſaffron, Japan earth, treacle, burnt ſugar, and oak-chips; the three former of theſe have but little to recommend them, but the others are found very ready, and very proper for the uſe.

Treacle gives a fine colour not much unlike that of the foreign brandies, and being neceſſarily uſed in a large quantity, as its colour is but dilute, it not only mends the bubble, or bead-proof, impaired by the rectification, but alſo gives it a fulneſs in the mouth; both which properties are very agreeable to the vulgar, who are the chief retail conſumers of theſe coarſe goods.

Burnt ſugar, that is, ſugar diſſolved in a little water, and ſcorched over the fire till it turns black, goes much farther in the colouring than treacle, and at the ſame time gives no ſweetneſs, but rather an agreeable bitterneſs; and thus recommends itſelf to the nicer palates, that are not for a luſcious ſpirit. Indeed ſugar, thus treated, tinges to a great perfection, and that without loſs of time, and with as much cheapneſs as can well be deſired.

The laſt article mentioned, namely oak-chips, is of all others the moſt natural for imitating the dye of foreign ſpirits, as it is the very wood of which the caſks they come over in are made, and from which they take that colour of which we are ſo fond. The colouring with oak has alſo this farther advantage in ſpirits meant as ſophiſtications of the foreign ones, that it will ſtand ſome teſts uſually had recourſe to on the occaſion, which the others will not ſtand.

Common ſpirit poured on oak-chips, and digeſted in a moderate heat, eaſily fetches out the reſinous part of the wood on which the colouring depends; but then it does not go near ſo far as the burnt ſugar; a large quantity of oak being required to colour a ſmall parcel of brandy, or ſpirits. It is adviſeable not to make the tincture every time, but to have recourſe to an extract of this wood in a liquid form: this extract is beſt made in two menſtruums, alcohol and water, and may be evaporated to any ſtrength, ſo that a very ſmall doſe of it will tinge a great quantity of liquor. The two liquid extracts will be mixed together, and as they will be apt to ſeparate in ſtanding, it will be proper to add to them, when newly made, a quantity of fine ſugar; this will give a body to the whole, and it will keep better from mouldineſs than it would without it. Shaw's Eſſay on Diſtillery.

Spirits, *Convertibility of.* This is a doctrine that has obtained among many of the moſt curious experimenters, and, indeed, the moſt intelligent of our chemiſts have always allowed, that provided proper care were taken in the getting together of the material, one ſpirit may always be changed into another, as brandy into rum, malt-ſpirit into brandy and brandy into malt-ſpirit. The principles on which this is believed are theſe.

All ſimple ſpirits (as they are called) conſiſt of four parts, water, oil, phlegm, and alcohol; the laſt of theſe is the eſſential part, and is what conſtitutes the whole a ſpirit. In reducing ſpirits, therefore, to their utmoſt degree of ſimplicity and purity, it is evident that the three ſuperfluous parts are to be got rid of, and the fourth left alone; by this means the alcohol is procured diſtinct, and is a liquor *ſui generis* of many peculiar qualities, not to be found in any other fluid.

Among others, it has theſe remarkable properties: 1. When abſolutely purified, it is an uniform and homogene liquor, capable of no farther ſeparation, without loſs or deſtruction of ſome of its homogeneous parts. 2. It is totally inflammable, leaving no ſoot nor any moiſture behind. 3. It has no peculiar taſte or flavour, any more than pure water, except what is owing to its nature as alcohol, or perfectly pure ſpirit. 4. It is an unctuous and criſpy fluid, running veiny in the diſtillation, and its drops rolling on the ſurface of any other fluid, like peaſe upon a table, before they unite. 5. It appears to be the eſſential oil of the body it is obtained from, broken very fine, and intimately and ſtrongly mixed with an aqueous fluid, which is aſſimilated, or changed in its nature in the operation. 6. And laſtly, it ſeems to be a kind of univerſal fluid, producible with the ſame properties from every vegetable ſubject; but to produce it thus requires ſome care in the operation. See Alcohol.

On theſe principles is founded the opinion, that all ſpirits may be reduced to a perfect ſimilarity, or ſameneſs, from whatever ſubject they were procured, and on this depends their convertibility into one another; for when once they are brought to this ſtandard of ſimplicity, there needs nothing more than to add the oil of ſuch of the finer ſpirits as is required to convert the ſpirit into that particular kind. By this means the ſame taſteleſs ſpirit, whether obtained from malt, ſugar, or grapes, may be made either into malt-ſpirit, brandy, or rum, by adding the eſſential oil of the grape, ſugar, or malt; and thus, what was once malt-ſpirit, ſhall become brandy, or whatever elſe the operator pleaſes.

Many methods have been attempted to obtain the firſt point, that is, the reducing of the ſpirit to perfect and pure alcohol. The moſt practicable means ſeem to be long digeſtion, and the repeated diſtillation from water into water, where the eſſential oil will at once be left upon two ſurfaces, and the acid imbibed. The ſhorter ways are thoſe by rectifying from neutral abſorbent ſalts and earths; ſuch as ſugar, chalk, and the like. And laſtly, the uſe of fixed alkalies may be tried, for theſe very forcibly keep down both the phlegm and oil; inſomuch that this laſt method promiſes to be the ſhorteſt of all, if the art were known of utterly aboliſhing the alkaline flavour, which the alcohol is apt to acquire in this operation, and which, for this purpoſe, is by no means ſuitable, as abſolutely deſtroying all vinoſity, which univerſally conſiſts in a fine volatile pungent acidity. The diſtillers are the only people whoſe buſineſs would lead them to make the experiment. This method of converting one ſpirit into another, would be of immenſe profit to them if they could perfectly ſucceed in it; but as it would require time and ſlow proceſſes to bring it about, there is but little hope of its ever being brought to bear among them, while they are in their preſent ſcheme of doing every thing with diſpatch and hurry.

Dr. Shaw has ſaid a vaſt deal in the praiſe of a taſteleſs ſpirit, which is producible from a vegetable ſubſtance, only overlooked, as he tells us, becauſe it is too common, with which all the foreign ſpirits might be imitated to the utmoſt perfection by means of their eſſential oils, all thin fine wines raiſed to any due degree of ſtrength, without giving them the brandy flavour, and many other things of great uſe performed; but he has not told us what the vegetable ſubſtance is from which we are to obtain this. Shaw's Eſſay on Diſtillery.

SPIRIT, *Ardent*, called alſo *ſpirit of wine*, becauſe it can only be obtained from ſubſtances which have undergone the vinous fermentation, is a very light, very volatile, very fluid liquor, perfectly white and limpid, and of a ſtrong, penetrating, agreeable taſte and ſmell. See ALCOHOL.

Spirits drawn from wine, ſuch as French brandy, may, in a great meaſure, be purified or rectified by ſimple diſtillation, in tall veſſels with a gentle heat, the pure ſpirituous parts riſing before the phlegm: if French brandy be thus diſtilled to one-half, the diſtilled ſpirit proves tolerably pure. See BRANDY.

But wine or brandy being in this country too dear an article for diſtillation, this purification is chiefly practiſed on the cheaper ſpirits of moloſſes and malt-liquors. To ſeparate the offenſive oil with which theſe abound, after they have been freed by diſtillation from the greateſt part of their phlegm, they are mixed with an equal quantity of ſpring-water, and the ſpirit drawn off again by a gentle heat: a conſiderable portion of the oil is thus left behind in the water, which now proves túrbid and milky, and very nauſeous both in ſmell and taſte. The firſt produce is the ſtrongeſt and pureſt, and when it has come over to the amount of ¼th of the whole contents of the ſtill, forms the rectified ſpirit. By repeating this ablution with freſh quantities of water, the fouleſt and moſt offenſive ſpirits may be purified from all ill flavour. To complete the purification, or free them from their remaining phlegm or oil, or the watery vapour which is raiſed even by the gentleſt heat in which they can be diſtilled, a little fixed alkaline ſalt, thoroughly dried and powdered, or lime, or ſome other article of a like kind, is added; which, imbibing the phlegm, is thereby diſſolved into a ponderous liquid, that does not mingle with the ſpirit, but ſettles at the bottom. If the ſpirit is very phlegmatic, four pints will require a pound of the alkali; if the diſtillation has been performed with due care, half this quantity, or leſs, will be ſufficient: in either caſe, if all the ſalt diſſolves, the ſpirit is to be digeſted with a little more, till at leaſt a part remains undiſſolved. The ſpirit now poured off is to be again diſtilled, in order to ſeparate from it a portion of the ſalt which has united with it, and which, though extremely minute, may in ſome reſpects change its qualities. As ſome particles of the alkali are apt to be carried up with it, even in the diſtillation, ſo as to communicate an ill flavour, or an urinous taſte, it is adviſeable previouſly to add a ſmall portion of calcined vitriol, or burnt alum and charcoal, which will completely abſorb the alkali, without giving any new impregnation to the ſpirit. Malt-ſpirits, when properly rectified, yield as pure and as ſtrong rectified ſpirit as brandy. Lewis's Mat. Med. See DISTILLATION, and SPIRITS, in the *Materia Medica*, infra.

When only a ſmall quantity of ſpirit of wine is to be rectified, the uſual operation for this purpoſe, by means of diſtillations of the ſpirit called aqua vitæ, obtained from the firſt diſtillations of liquors that have undergone the ſpirituous fermentation, and which are overcharged with a large quantity of phlegm and light oil, is difficult. Theſe diſtillations being ſlowly conducted with a gentle fire and water-bath, yield but a ſmall quantity of that liquor, which, being the moſt volatile, riſes firſt with the leaſt heat, and which is the true or rectified ſpirit of wine. Several chemiſts, therefore, in order to obtain a larger quantity of the firſt ſpirit, propoſe to mix with the ſpirit of wine ſome intermediate ſubſtances, to abſorb and retain its phlegm and oil, ſuch as dried and calcined ſalts, very dry chalk, &c. Kunckel propoſes to ſeparate more effectually the oil, by adding to the ſpirit a large quantity of water, and by diſtilling this diluted ſpirit with a very gentle heat. But the trouble and inconvenience of depriving the ſpirit of wine of the water with which it was diluted in this proceſs, may be avoided, by rectifying at once a large quantity of aqua vitæ. Nothing more is required to obtain at once a conſiderable quantity of pure ſpirit of wine, than to ſet aſide the twelve or fifteen pints firſt drawn over from a large quantity, *e. g.* from three hundred pints of aqua vitæ, diſtilled with a very gentle fire in a large alembic. As the moſt ſpirituous, leaſt aqueous, and leaſt oily part of it always riſes firſt, theſe twelve or fifteen pints are perfectly rectified ſpirit of wine, eſpecially when the heat has been well conducted.

By thus keeping apart portions of the ſpirit obtained, at different times, we may have ſpirit of wine of the ſeveral degrees of ſtrength and purity. The weaker ſpirit may, by another diſtillation, be again rectified; and the ſpirit of moderate ſtrength may be preſerved for many uſes. The method is followed by M. Beaumé in the rectification of ſpirit of wine, and is certainly the moſt convenient and the beſt.

A perfectly rectified ſpirit of wine, or ſuch as is entirely freed from water, is undoubtedly a thing of frequent and neceſſary uſe in the nice operations of chemiſtry.

It had uſed to be prepared, either by often diſtilling the ſpirit, and every time drawing over only half of it, and repeating this till the half remaining in the cucurbit appeared as ſtrong as that drawn over; or elſe by raiſing it to a great height from the body of the veſſel, and this in a very gentle heat, ſo that ſpirit alone could riſe, the water not being capable of being driven ſo far by that degree of heat.

But the accurate Boerhaave always found upon trial, that there was ſtill remaining ſome water in theſe ſpirits, whether prepared by the firſt or ſecond proceſs, or both. Boerhaave's Chem. part ii. p. 124.

The method he therefore invented is this: fill a ſtill half full of the ſpirit prepared for alcohol in one or other of theſe ways, and add to it half a pound of pure decrepitated, and perfectly dried ſea-ſalt; put this in hot, then place on the head, and carefully lute the junctures; leave this for twelve hours in a heat ſo ſmall, as not to make the alcohol boil, then diſtil off the ſpirit; keep the firſt two ounces apart, becauſe ſome aqueous vapour may have happened to lodge in the head or worm of the ſtill, which this certainly waſhes off; after this receive two-thirds of the following alcohol into a pure dry glaſs veſſel, and keep it perfectly ſtopped; then draw off the remainder, and keep that by itſelf: there will remain a moiſt ſalt in the ſtill, which has attracted the aqueous matter of the alcohol, and held it ſo down, that it could not riſe by the heat of boiling water, which is all that muſt be uſed in this diſtillation; and the ſalt having been firſt decrepitated, never makes any change in the alcohol by adding any thing to it. By this means an alcohol is prepared perfectly pure, and fit for all the uſes of chemiſtry.

For the teſts and properties of pure alcohol, ſee ALCOHOL.

M. Reaumur diſcovered, that a mixture of ſpirit of wine and water acquired a ſpecific gravity greater than that which would arithmetically reſult from the proportions employed of each of theſe liquors. Thus, fifty meaſures of ſpirit of wine, and fifty meaſures of water, mixed together, were found to make only ninety-eight meaſures; but in what progreſſion the denſity is increaſed by mixing various proportions of the two liquors, had not been determined till M. Briſſon made a ſet of experiments with that view; an account of which is given in the Memoirs of the Academy of Sciences of Paris, for the year 1769.

From his experiments he has conſtructed the following table, which ſhews this progreſſion, and alſo enables us to diſcover the proportion of ſpirit of wine and water, in any given mixture of theſe (as brandies, rums, &c.), the ſpecific gravity of which is found to correſpond with any of the ſpecific gravities in the table. Thus, for inſtance, if we find upon accurate trial, that the ſpecific gravity of the rum, brandy, or other mixture, whoſe ſtrength is required to be known, be to that of water as $942\frac{1}{2}$ to 1000, we learn, by inſpection of the table, that this ſpirituous mixture conſiſts of equal parts of water and ſpirit of wine, of which ſpirit the ſtrength is ſuch, that its denſity is to that of the water as 837 to 1000. The firſt column ſhews the proportion of well rectified ſpirit of wine in the mixture; the ſecond column ſhews the proportion of the water in the mixture; the third column ſhews the ſpecific gravity of the mixture; the fourth column ſhews the difference between the ſpecific gravity of the mixture and that of the preceding mixture; and the fifth column ſhews the proportion which the ſeveral augmentations of denſity, cauſed by penetration of the two liquors, have to each other, that is their progreſſion.

Spirit of Wine.	Water.	Specific Gravity.	Differences.	Proportionable Augmentations of Denſity from Penetration.

Spirit of wine is uſed in dyeing, as a non-colouring drug, and though it gives no colour itſelf, it ſerves to prepare the ſtuffs to receive other colours. Its conſumption is alſo very conſiderable in ſeveral other works and manufactures, particularly the making of varniſh.

Proof-ſpirit cannot be uſed for burning in lamps, for diſſolving reſins, and for making varniſh; and there is alſo a great number of tinctures, ſolutions, and mixtures, for which it cannot ſerve; but rectified ſpirit, or alcohol, beſides its ready uſe for medicinal purpoſes, may, when the ſpirit is of a proper kind, be made into punch, and all other mixtures, with greater purity, and much greater certainty and exactneſs in point of ſtrength. See next article and ALCOHOL.

SPIRITS, in the *Materia Medica*, "rectified ſpirit" of the London Pharmacopeia; "alcohol," "ſpiritus vinoſus rectificatus ſive puriſſimus," Edinb.; "ſpiritus vinoſus rectificatus," Dub.; is alcohol nearly in the higheſt ſtate of concentration in which it can be eaſily prepared in the large way for the purpoſes of trade. The London and Edinburgh colleges ſtate its ſpecific gravity to be to that of water as 835 to 1000, while the Dublin college ſtates it at 840. The Edinburgh college names this ſpirit alcohol; but directions being given both by the London and Dublin colleges, for the preparation of a ſtill ſtronger ſpirit, the name of alcohol, in their pharmacopeias, is judiciouſly retained for the ſtronger ſpirit, while that of rectified ſpirit is applied to the preſent preparation.

The alcohol of the Lond. Ph. is prepared by taking of rectified ſpirit a gallon, and of ſubcarbonate of potaſs, three pounds: add a pound of the ſubcarbonate, previouſly heated to 300 degrees, to the ſpirit, and macerate for 24 hours, frequently ſhaking the mixture; then pour off the ſpirit, and add the remainder of the ſubcarbonate, heated to the ſame degree; and laſtly, diſtil the alcohol from a water-bath, and preſerve it in a well-cloſed veſſel. The ſpecific gravity of this alcohol is to that of diſtilled water as .315 to 1,000.

The alcohol of the Dub. Ph. is prepared by taking of rectified ſpirit of wine, a gallon; pearl-aſhes, dried at a heat of 300°, and ſtill hot, a pound; cauſtic kali, in powder, an ounce; muriate of lime, dried, half a pound. Mix the ſpirit and the kali; add the pearl-aſhes, previouſly reduced to powder, and digeſt the mixture for three days in a cloſed veſſel, frequently ſhaking it; then pour off the ſpirit; mix with it the muriate of lime; and laſtly, diſtil with a moderate heat, until the reſidue begins to thicken. The ſpecific gravity of this ſpirit is to that of diſtilled water as 315 to 1000.

Rectified ſpirit of the ſpecific gravity of 835, contains about 15 *per cent.* of water; and to free it from this is the intention of the above proceſſes. The Edinburgh college has no proceſs for the preparation of pure alcohol, which may be eaſily diſpenſed with; but it has very improperly given this title to the rectified ſpirit of the other pharmacopeias. The theory of the operation is ſufficiently obvious. The affinity of the alkali and the muriate of lime for water is much greater than that of the ſpirit: it is, therefore, attracted by theſe ſubſtances, and prevented from riſing with the ſpirit during the diſtillation, by which means the alcohol comes over in a very highly concentrated ſtate. Of the two proceſſes, that of the Dublin college is to be preferred; muriate of lime being a much more powerful agent for ſeparating the water, which is the object in both, than ſubcarbonate of potaſs.

Dr. Black thus obtained alcohol of the ſp. gr. of 800°, and Richter procured it ſo low as 0.792, in the temperature of 68° Fahr. at which degree of concentration it may be regarded almoſt as pure alcohol, or alcohol perfectly free from water. That of the pharmacopeias is not free from water, though more than ſufficiently concentrated for all the purpoſes of pharmacy.

The following Table, drawn up by Lowitz, with an additional column by Dr. Thomſon, ſhews the ſpecific gravity of different mixtures of pure alcohol, of a ſpecific gravity .791, and diſtilled water, at the temperatures of 60° and 68° of Fahrenheit.

* Alcohol of the London and the Dublin Pharmacopeias. † Ditto (Edinburgh); rectified ſpirit (London). ‡ Rectified ſpirit (Dublin). § Proof ſpirit (Lond. Dub.) ‖ Ditto (Edinburgh).

In the extract from Mr. Gilpin's table (ſee *Specific* GRAVITY), the ſtandard ſpirit was of the ſpecific gravity of 0.825, or contained 89 pure alcohol, and 11 water, in 100 parts.

Pure rectified ſpirit has a fragrant odour, and a hot highly pungent taſte. It is colourleſs; always fluid; cannot be congealed at any known degree of cold; evaporates ſpeedily at the ordinary temperature of the atmoſphere; boils at 163° Fahrenheit; and is extremely inflammable, burning with a blue lambent flame, without any ſenſible ſmoke. Like alcohol, it combines with water in every proportion; and, on account of its affinity for water, precipitates many of the neutral ſalts from their aqueous ſolutions. It is capable of diſſolving many ſaline bodies, and is the proper ſolvent of the greater number of the proximate principles of vegetables. Its conſtituents are 85 of pure alcohol and 15 of water, in 100 parts, when its ſpecific gravity is 835, at a temperature of 60° of Fahrenheit; but 83 only of pure alcohol, and 17 of water, when it is 840, as deſignated by the Dublin college.

Rectified ſpirit is a very powerful ſtimulant. In its undiluted ſtate it is never exhibited as a remedy; and is merely employed for forming the diluted ſpirit, and as a pharmaceutical agent.
